**BUTLER, SAMUEL** (1835-1902), English author, son of the Rev. Thomas Butler, and grandson of Samuel Butler, Bishop of Lichfield (q.v.), was born at Langar, Notts., on Dec. 4, 1835. He was educated at Shrewsbury School and at St. John's College, Cambridge, where he narrowly missed a classical fellowship. He wished to be a painter, and refused, on grounds of religious doubt, to enter the Church, for which he had been intended. After some differences with his father on this head, he emigrated in 1859 to New Zealand, and established a sheep-run on the Rangitata, with capital advanced by his father. He had already been connected at St. John's with an undergraduate paper, *The Eagle*, and in New Zealand he contributed various articles to the press, including a dialogue, *Darwin and the Origin of Species* (1862), and a sketch, *Darwin among the Machines* (1863), which was the germ of his best-known work, *Erewhon*. His first book, *A First Year in Canterbury Settlement* (1863), describing his New Zealand experiences, was edited and published by his father from his letters during his absence from England. In 1864, having doubled his capital, he sold his sheep-run, and returned to England, taking rooms in Clifford's Inn, where he lived for the rest of his life. At this time he possessed a competence; but this was subsequently lost in speculative ventures, and from 1874 to 1886 his circumstances were embarrassed. In 1886, however, his father's death ended his monetary troubles. On his return to England he had begun to study painting seriously, and from 1868 to 1876 he exhibited regularly at the Royal Academy. One of his pictures, "Mr. Heatherley's Holiday," is now in the National Gallery of British Art. At Heatherley's school of painting in Newman Street he met Eliza Mary Anne Savage, who became his closest friend. He corresponded regularly with her until her death in 1885. It appears that she was in love with him; but she was lame, in

poor health, and not beautiful. Butler never married. In his later years his closest friend was Henry Festing Jones, who wrote his life, and collaborated with him in the illustrating of his Italian books and in his musical compositions. These include *Gavottes, Minuets, Fugues, and other Short Pieces for the Piano* (1885), *Narcissus: a Cantata in the Handelian form* (1888), and *Ulysses: an Oratorio* (1904). Butler was throughout his life passionately devoted to Handel, whom he ranked very much above all other composers.

Butler lives, not by his musical compositions or his pictures, but by his books. His first important work was *Erewhon, or Over the Range* (1872), a story of a visit to an imaginary country shut off from the world. The account of Erewhonian manners enables Butler to proclaim his own philosophy of life in satirizing the manners of his age. *Erewhon*, which had a popular success denied, in Butler's lifetime, to all his later books, was followed by *The Fair Haven* (1873), a satirical defence of "the miraculous element in Our Lord's ministry here on earth," purporting to be written by one, John Pickard Owen, of whom a satirical biography is prefixed. *The Fair Haven*, based on a pamphlet on *The Evidence for the Resurrection*, which Butler had printed privately in 1865, appeared without his name, and was taken seriously by some reviewers. In a second edition, issued in the same year, Butler disclosed his authorship and intention. Meanwhile, he had been following up his early interest in the doctrine of evolution. In 1872 he twice stayed with Charles Darwin, with whom, and with his son, Francis, he was on terms of friendship. But his study of evolution led him to a sharp dissent from Darwin's views, and to the upholding of a doctrine which he traced back in part to Buffon, Lamarck, and Erasmus Darwin, whose contributions to the theory of evolution seemed to him to have been overlaid by the praise accorded to Charles Darwin's theory of Natural Selection. In 1877 he published the first of his books on this subject, *Life and Habit*, in which he developed the doctrine that heredity, and therefore evolution, depended not on the natural selection of chance variations or "sports," but on an "unconscious memory," transmitted as habit from generation to generation, and tending constantly to grow with the life of the race. *Life and Habit* was followed by *Evolution Old and New* (1879), *Unconscious Memory* (1880), and *Luck or Cunning?* (1886), in which Butler's biological theories were further developed. These writings, by means of which he held that he had achieved "the re-introduction of teleology into organic life," received no serious notice from his contemporaries, though they have been far more favourably considered by later scientists [cf. Prof. Bateson, in the Darwin centenary volume, *Darwin and Modern Science* (1909)]. Natural selection, as interpreted by Darwin, seemed to Butler to remove all idea of purpose from the universe, and to depend on the occurrence of variations, or "sports," whose appearance it left totally unexplained. Against this view, he maintained that variation was due, not to "luck," but to the striving (or "cunning") of the individual in adapting itself to its environment, and handed on by the inheritance of "unconscious memory" or "habit."

Having completed his contribution to the theory of evolution, Butler found himself attracted to a problem of a very different order—the Homeric question. He developed the belief that the *Iliad* and the *Odyssey* were by different writers—the *Iliad* by a native of the Troad, veiling his sympathy for the Trojans against the Greeks, and the *Odyssey* by a woman, a native of Trapani in Sicily. These views were first put forward in periodical writings and in two pamphlets, *The Humour of Homer* (1892) and *On the Trapanese Origin of the Odyssey* (1893). His views about the *Odyssey* were further developed in *The Authoress of the Odyssey* (1897), and he also translated both the *Iliad* (1898) and the *Odyssey* (1900) into colloquial prose. His remaining works include his charming *Alps and Sanctuaries of Piedmont and the Canton Ticino* (1881) and *Ex Voto: an Account of the Sacro Monte or New Jerusalem at Varallo-Sesia* (1888), memorials of his frequent holidays in Italy, first visited by him as an undergraduate, and subsequently re-visited on all possible occasions. He also wrote *The Life and Letters of Samuel Butler* (1890), a voluminous study of his grandfather's life and work, a book on

*Shakespeare's Sonnets* (1899), and *Erewhon Re-visited* (1901), an amusing sequel to *Erewhon*.

Butler's one novel, *The Way of All Flesh* (1903), not published until after his death, though it was written between 1873 and 1885, is by far his most important work. It is largely autobiographical, and the characters are mostly taken, with changes, from real life. Theobald and Christina Pontifex are based on Butler's parents, Alethea on Miss Savage, and Dr. Skinner on Dr. Kennedy, Butler's head master at Shrewsbury, while Butler himself appears twice, as both Overton and Ernest Pontifex. *The Way of All Flesh* is the quintessence of its author's commonsense philosophy. It wages war on all extremes (*surtout point de zèle* was a favourite maxim of Butler's), on all shams and pretences—above all those of which the pretenders are unconscious—on all attempts to take either life or death too seriously. It is full of a faintly bitter irony, which the author turns on occasion against himself as well as his victims. It is caricature; but no book gives a better satiric picture of family life and manners in mid-Victorian England. With Butler's books on evolution, it has notably influenced Bernard Shaw, especially in his writings on parents and children.

Butler wrote a good, plain, vigorous English, almost devoid of ornament. "A man," he wrote at the age of 22, "should be clear of his meaning before he endeavours to give it any kind of utterance, and, having made up his mind what to say, the less thought he takes how to say it, more than briefly, pointedly, and plainly, the better." His *Notebooks*, from which a selection was published in 1912, are full of good and characteristic things said briefly, pointedly and plainly. There will be found also his famous *Psalm of Montreal*, first published in the *Spectator* in 1878.

See *Samuel Butler: Records and Memorials* (privately printed, 1903), H. F. Jones, *Charles Darwin and Samuel Butler* (1911), H. F. Jones *The Life of Samuel Butler* (1919), and, for a critical study, C. E. M. Joad, *Samuel Butler* (1924). (G. D. H. C.)

**BUTLER, SIR WILLIAM FRANCIS** (1838-1910), British soldier, entered the army as an ensign in 1858, becoming captain in 1872 and major in 1874. He took part with distinction in the Red river expedition (1870-71) and the Ashanti operations of 1873-74 under Wolseley, and received the C.B. in 1874. He served with the same general in the Zulu War (brevet lieutenant-colonel), the campaign of Tel-el-Kebir, after which he was made an aide-de-camp to the queen, and the Sudan 1884-85, being employed as colonel on the staff 1885, and brigadier-general 1885-86. In the latter year he was made a K.C.B. He was colonel on the staff in Egypt, Feb. 1890 to Dec. 1892, and brigadier-general till Nov. 1893, then appointed to Aldershot as major-general. Later he commanded the south-eastern district. In 1898 he succeeded General Goodenough as commander-in-chief in South Africa, with the local rank of lieutenant-general. For a short period (Dec. 1898-Feb. 1899), during the absence of Sir Alfred Milner in England, he acted as high commissioner, and as such and subsequently in his military capacity he expressed views on the subject of the probabilities of war which were not approved by the home government; he was consequently ordered home to command the western district, and held this post until 1905. He was promoted lieutenant-general in 1900. He had long been known as a descriptive writer, since his publication of *The Great Lone Land* (1872) and other works, and he was the biographer (1899) of Sir George Colley. Sir William Butler died at Tipperary on June 7 1910. He married in 1877 Miss Elizabeth Thompson, an accomplished painter of battle-scenes.

Among Lady Butler's more famous works were "The Roll Call" (1874), "Quatre Bras" (1875), "Rorke's Drift" (1881), "The Camel Corps" (1891), and "The Dawn of Waterloo" (1895). See her *Autobiography* (1923).

**BUTLER**, a city of Pennsylvania, U.S.A., on Cōhoquenessing creek, about 30m. N. of Pittsburgh; the county seat of Butler county. It is served by the Baltimore and Ohio, the Pennsylvania, the Buffalo, Rochester and Pittsburgh, and the Bessemer and Lake Erie railways. The population in 1920 was 23,778, and was 23,568 in 1930 by the Federal census. It is built on a hill about 1,000ft. above sea-level and commands extensive views of the

valley. Oil, natural gas, limestone, coal, and iron abound in the vicinity, and the city has important manufactures, including plate-glass, steel cars, car wheels, motor tyres, metal pipe, oil-well machinery, and petroleum products. The total factory output in 1925 was valued at \$22,396,963. When Butler county was formed in 1802, this site was selected for the county seat, and in 1803 the borough was laid out and incorporated. A city charter was secured in 1917. County and city were named after General Richard Butler, a Revolutionary soldier and friend of Washington.

**BUTLER**, a domestic servant who superintends the wine-cellar and acts as the chief male servant of a household; among his other duties are the conduct of the service of the table and the custody of the plate. The butler of a royal household was an official of high rank, whose duties, though primarily connected with the supply of wine for the royal table, varied in the different courts in which the office appears. In England, as superintendent of the importation of wine, a duty was payable to him (*see PRISAGE AND BUTLERAGE*); the butlership of Ireland, *Pincerna Hiberniae*, was given by John, king of England, to Theobald Walter, who added the name of Butler to his own; it then became the surname of his descendants, the earls, dukes and marquesses of Ormonde (*see BUTLER* [family]). Butler is from the Late Lat. *buticularius*, *buticula*, a bottle, through the O.Fr. *bouteillier*.

**BUTLERAGE** and **PRISAGE**: *see PRISAGE AND BUTLERAGE*.

**BUTO**, the Greek name of the Egyptian goddess Uto (hierogl. *W'zy-t*), confused with the name of her city Buto (*see BUSIRIS*). She was a cobra-goddess of the marshes, worshipped especially in the city of Buto in the north-west of the Delta, and at another Buto (Hdt. ii. 75) in the north-east of the Delta, now Tell Nebesheh. This western Buto was the capital of the kingdom of Northern Egypt in prehistoric times before the two kingdoms were united; hence the goddess Buto was goddess of Lower Egypt and the North. To correspond to the vulture goddess (Nekhbi) of the south she sometimes is given the form of a vulture; she is also figured in human form. As a serpent she is commonly twined round a papyrus stem, which latter spells her name; and generally she wears the crown of Lower Egypt. The Greeks identified her with Leto; partly by the resemblance of name, partly by the myth of her having brought up Horus in a floating island, resembling the story of Leto and Apollo on Delos. Herodotus describes the temple and other sacred places of (the western) Buto, and refers to its festival, and to its oracle. It eventually became, at a very late date, the capital of a nome, in this case called Phtheneto, "the land of (the goddess) Buto." The second Buto (hierogl. *Im-t*) was capital from early times of the 19th nome of Lower Egypt.

**BUTON** (Dutch, *Boeton*), island off the S.E. of Celebes, one of a group of which the most important are Buton, Muna, Kabena, and Wowoni. Buton Strait, between Buton and Muna, (port, on the E. coast, Raha) is very narrow, and difficult to navigate, but very beautiful. Buton lies in the track from Macassar to Buru and Amboyna. It is over 100 miles long, and has an area of about 2,000 sq. miles. It has an axial chain of limestone hills (highest point Kepala-Ogena, 3,500ft.) thickly forested as is the whole island. The coast people are mostly Mohammedan Buginese, but the interior also has pagan peoples. There are three classes—descendants of nobles, free inhabitants, and slaves. They carry on weaving, and copperwork but are chiefly trading sailors and fishermen, and their well built *prahus* traverse all the seas of the Archipelago. Houses are built of wood, on piles, and sometimes villages are in shallow water off shore in more or less circular form, with approach by a bamboo causeway. Buton formerly had an evil reputation for piracy, and on the S. coast the old pirate haunt of Wasumba is still to be seen, surrounded by thick walls of chalk-blocked coral, and not far from the village of Wabula. Buton comes under the jurisdiction of Celebes, but there is a local sultan, who is elected by a council in which Dutch officials participate and who lives at Wabula, in a *kraton*, or fortress, which has bastions, with loop-holes, and is situated on the top of a steep hill, at some distance from the coast. Teak is found, and is used for boat-building, coconuts are grown, and

there is some trade in copra, and a kind of small dried fish is marketed. A few of the natives engage in pearl-dealing, but not all the pearls they handle are genuine. The port for the island is Buton, at the N.W. end of the Strait. An assistant-resident is stationed in Ban-Bau (Buton).

**BÜTOW**, chief town of an eastern sub-division in the district of Köslin, in the Prussian province of Pomerania. Pop. (1925) 8,873. It is a railway junction and a local agricultural centre.

**BUTRINTO**, a small Albanian town which can be reached from Argyrocastro but less easily from Janina, from which it is separated by a range of hills. The town occupies the site of an ancient fortress on a headland facing the northern end of Corfu. It is on the shores of a fine bay a mile in length with an anchorage of 14 to 16 fathoms. The harbour is too far to the south to be worth developing and it is badly served by communications inland. It is only a few miles from the present Greco-Albanian frontier and so is subject to rapid occupation in the event of war. It lies on a rough coast-road that leads northwards to Valona. Its proximity to Corfu would prevent free access to it by sea if Corfu were occupied by hostile forces. Extensive fisheries are carried on at Butrinto and the markets of Corfu are largely supplied from this source. The lakes and marshes near the town abound in waterfowl of many kinds. The town is scantily populated and in no sense modernized. The entrance to the harbour is largely silted up.

Butrinto is usually identified with the ancient Buthrotum, a city said to have been founded in the time of the Trojan war. It seems to have been an Illyrian or Epirote town of no great importance and not a Greek city state. It became, however, a Roman colony by the time of Strabo. In the middle ages it was made a Venetian fortress with fortifications that still survive. It remained in Venetian hands until 1797 when Ali Pasha of Tepelen occupied it.

**BUTT, DAME CLARA** (1873—), English contralto singer, was born at Southwick, Sussex, on Feb. 1, 1873. She was trained at the Royal College of Music, and made her debut in a students' performance of Gluck's *Orfeo* at the Lyceum theatre in 1892. She possessed a contralto voice of exceptional power and wide range, and became a public favourite as a ballad and oratorio singer. In 1900 she married the singer Kennerley Rumford (b. 1870), and with him sang constantly at concerts in all parts of Great Britain, also undertaking various long tours in the colonies. During the World War she devoted the proceeds of many of her concerts to war charities, and was in 1917 created D.B.E.

**BUTT, ISAAC** (1813–1879), Irish lawyer and Nationalist leader, was born at Glenfin, Donegal, in 1813, his father being rector of Stranorlar. He was a brilliant student at Trinity college, Dublin, where he helped to found the *University Magazine* in 1833, and where he was appointed professor of political economy in 1836. Called to the Irish bar in 1838, he was made a Q.C. in 1844, and took part in all the important Irish law cases of the time, being engaged in the defence of Smith O'Brien in 1848, and of the Fenians between 1865 and 1869. He began by taking an active part in politics as a Conservative, was a defender of the old corporation, and of Protestantism, and started the *Protestant Guardian*, which later became part of the *Orange War*; in 1840 he was chosen to defend the old corporation of Dublin before the bar of the House of Lords. Butt was also a warm supporter of the union. In 1852 he was returned to parliament by Youghal as a Liberal-Conservative, and retained this seat till 1865. During his parliamentary career he drifted away from conservatism, and by 1865, when he returned to Ireland, he was definitely Liberal. Disappointment at the disestablishment of the Irish church drove Butt with other Irish Protestants into union with the Nationalists, and as leader of this coalition he evolved the federal theory of Home Rule. At a large meeting on May 19, 1870, in Dublin he inaugurated the Home Rule movement, and after his election in 1871, for Limerick, he found himself at the head of a party of 57 members. The Home Rule league was founded in 1872, but gradually the Protestant and Conservative members dropped out; Butt himself disapproved of violent methods and obstruction in parliament, and remained

convinced that the union between Ireland and England must stand. The party got beyond his control, and extremists accused him of being a political traitor, his false position assisted in breaking down his health, and he died in Dublin, on May 5, 1870.

**BUTT.** (1) A cask for ale or wine, with a capacity of about two hogsheads (108 gal.; *see* HOGSHEAD). (2) The thick end of anything, as of a fishing-rod, or the wooden end of a rifle, shaped to fit against the firer's shoulder, also the stump of a tree. (3) A mark for shooting, or a mound or bank, sometimes called a "stop-butt," in front of which are placed the targets in artillery or musketry practice (Fr. *but*, a goal, and *butte*, a target, a rising piece of ground). The word is used figuratively of a person or object at which derision or abuse is levelled.

**BUTTE**, the largest city of Montana, U.S.A., on the west slope of the continental divide, at an elevation of 5,755ft.; the county seat of Silver Bow county. It is on Federal highways 10 and 91, and is served by four trans-continental railways: the Chicago, Milwaukee, St. Paul and Pacific, the Great Northern, the Northern Pacific, and the Union Pacific. It has a fine airport covering nearly 60 acres. The area is 5.2sq. miles. The population in 1920 was 41,611, of whom 11,454 were foreign-born white, and was 39,532 in 1930 by the Federal census; in 1880 the population was 3,363, and in 1900, 30,470.

Butte is the principal railroad and business centre of the Rocky Mountain north-west, the largest city between Minneapolis and Spokane north of Salt lake. Basically it is a huge mining camp, on "the richest hill in the world." Its surface in the mining district is gridironed with railway tracks to the mines and dotted with shaft-houses, smokestacks, and steel hoist-frames. Underground the rocks are honeycombed with workings, some to a depth of 3,600 feet. It is also an important trading centre, wholesale and retail, has a large tourist traffic, and manufactures a variety of products, valued in 1925 at \$4,108,478. Formerly fumes from the smelters killed all vegetation, and the general appearance of the city was desolate indeed by day, though at night it had a fantastic beauty. At present, however, most of the ore is treated at Anaconda and Great Falls; trees and grass have reappeared, and some beautiful residential districts and parks have been developed. The assessed valuation of property in 1925 was \$19,350,785. The Montana school of mines, established in 1893, is situated here.

Gold was panned from gravel near the present site of Main street in 1864, and before these placer operations were worked out (1867) they had yielded about \$1,500,000. Silver ores were first successfully treated in 1875. Production of silver reached its peak in 1887, and practically disappeared as a primary industry with the drop in the price in 1893. Production of copper on a large scale began in 1882, and by 1900 the output amounted to nearly half the total for the country. To the end of 1924 the Butte district of a few square miles produced 8,622,814,852 lb. of copper, besides 190,993,827 lb. of lead, 1,876,718,111 lb. of zinc, 1,630,489 oz. of gold, and 399,801,572 oz. of silver, amounting in value to \$1,841,531,619. The city was laid out in 1866, and incorporated in 1879. It grew slowly until the railways reached it in the '80s. The population was 241 in 1870; 3,363 in 1880; 10,723 in 1890; and 30,470 in 1900. There are hot medicinal springs at several points near by. To the west is Big Butte, a sharp conical peak, from which the city takes its name. The Lewis and Clark national monument, 45m. East, includes a cavern 600 x 400ft. in size, not yet fully explored, with intricate passages and numerous chambers filled with curious stalagmites and stalactites.

**BUTTE** or **BUTE** (Fr. *butte*, a hillock or rising ground), a word used in the Western States of North America for a flat-topped hill surrounded by a steep escarpment from which a slope descends to the plain. It is sometimes used for "an elevation higher than a hill but not high enough for a mountain." The butte capped by a horizontal platform of hard rock is characteristic of the arid plateau region of Western U.S.A. The term "knob" is occasionally used for the same feature and represents a reasonable English description of the shape.

**BUTTER.** It is calculated that in England and Wales about 15% of all the milk produced is made into butter on farms. About 27 lb. of milk are required to make one pound of butter, and on this basis the production of butter is 28,450 tons of which 5,750 tons are consumed in farm households. A certain proportion of milk is sold by farmers to factories and creameries and there made into butter.

Although butter has been made on English farms from the earliest days of farming, it now takes a comparatively low place in the list of farm products. Reckoning by value it represents less than three % of the total farm output. The sale of liquid milk is generally more profitable than butter-making, while the absence of competition in the one case and its steady increase in the other makes milk-selling "the line of least resistance."

The imports of butter into Great Britain are large. In 1927 they were 5,827,000cwt. To this large quantity the chief contributors were as follows:—

| Country                    | Cwt.      |
|----------------------------|-----------|
| Denmark . . . . .          | 1,995,000 |
| New Zealand . . . . .      | 1,261,000 |
| Australia . . . . .        | 489,000   |
| Argentina . . . . .        | 420,000   |
| Irish Free State . . . . . | 586,000   |
| Russia . . . . .           | 350,000   |
| Finland . . . . .          | 205,000   |
| Sweden . . . . .           | 166,000   |
| Netherlands . . . . .      | 170,000   |
| France . . . . .           | 66,000    |
| U.S.A. . . . .             | 672       |
| Canada . . . . .           | 423       |

As margarine competes with, and is a substitute for butter, it should be added, in this connection, that the imports into Great Britain of that commodity amounted to 1,185,000cwt., nearly all of which came from Holland.

The international trade in butter is extensive. Great Britain is much the largest buyer, taking about six times as much as all other importing countries and thus dominating the trade. But in the aggregate the exports to other countries are considerable. In Europe, Belgium, Switzerland, Norway, Czechoslovakia, France, Austria and Germany are importing countries, while outside Europe the United States, Central America, Egypt, Algiers and South Africa also take greater or less quantities. Some of these countries, such as France, export as well as import butter, but they rank as importing countries if their imports normally exceed their exports. Even Great Britain, although typically an importing country, exports annually a small quantity of native and a considerable quantity of imported butter. Butter is transhipped to the Irish Free State, Germany, Holland, Belgium, the United States and France.

One explanation of this apparent anomaly is that there are various kinds and qualities of butter on the wholesale markets with different levels of price. A country may export one quality and import another. On the English markets, home produce is seldom or never quoted in bulk, but if of first quality it usually sells at a higher price per lb. than imported butters. Among these, Danish and Irish creamery butter rank highest in price, Dutch, New Zealand, Australian and Argentina coming next, and Siberian last.

Changes in the taste of the public affect the demand for particular kinds of butter. At one time, not so long ago, a rather heavily salted, highly coloured butter was generally favoured, but the main bulk of the supplies now are very lightly salted and uncoloured. This change in taste is attributable largely to the influence of Danish butter which has set a standard to which the mass of the people have become accustomed. The natural colour of butter is a pale yellow unless it is made from the milk of cows such as Jerseys, which give exceptionally rich milk. The artificial colouring of butter is now very little practised. Another influence in the same direction has been the institution of instruction in, and demonstration of, butter-making. The "working dairy" was in innovation 40 years ago, but at every important agricultural show it is now one of the regular attractions. Butter-making

competitions at the Royal Agricultural Show and the Dairy Show, attract competitors from all parts of Great Britain and the art of butter making by the most modern methods and with the latest appliances is there demonstrated. (See DAIRY FARMING.)

(R. H. R.)

**United States.**—Butter was first made in the United States on the farms. With the coming of the industrial age, and with it the larger units of manufacture, the handicraft method of making butter gradually gave way to the factory. The first creamery in the United States was built in Campbell hall, Orange county, N.Y., in 1856.

The size of the creamery has grown from the little neighbourhood factory to the large centralized creamery which receives cream from a radius of several hundred miles. The first creameries had a daily capacity of only a few hundred pounds of butter. The milk was delivered by the farmers at the plant, where it was skimmed from cans and vats after it had stood one or two days. Now the warm milk is separated by the farmer immediately after it is milked and the cooled cream is delivered to the creamery. The neighbourhood creamery has an average annual output of about 250,000 lb. of butter, which is marketed through the city butter-dealer. In a few cases a number of small creameries have organized a co-operative marketing agency. The most outstanding association of the sort is the Land O' Lakes creameries, which distributes the butter for 420 creameries of Minnesota and Wisconsin. The largest butter factories are found in large cities, where the finished product is marketed soon after it is made. A few single factories have an annual capacity of approximately 15,000,000 lb. and one or two companies with a series of 15 or 20 creameries are manufacturing over 60,000,000 lb. of butter in a year.

The per capita consumption of butter in the United States is 17.5 pounds. This is about the same as that of the United Kingdom but 10 lb. less than the Canadian citizen eats. The total amount of butter produced in the United States is around 1,600,000,000 lb. annually, which is about twice that of any other nation. Approximately 35% of the milk produced in the United States is manufactured into butter. The United States imports a little more butter than it exports.

Butter is made as follows: as quickly as the milk is separated the cream is cooled. The cream is delivered to the creamery once every two or three days, where it is graded in at least two classes, sweet and sour. If sour, the acidity is standardized to about .25% lactic acid by the use of a carbonate or a lime. Then it is pasteurized, and if ripened cream butter is to be made a pure culture of *streptococcus lactis* is introduced to start the desirable souring process. If sweet cream butter is to be made no starter is added. The best storage butter is made from unripened or sweet cream. After pasteurization and ripening the cream is held over night, when it is churned, washed, salted and worked in the combined churn and worker. The market requirements determine the amount of colour and salt that should be used. Good creamery butter has a composition of about 81% fat, 15.5% water, 2.7% salt and 0.8% casein and ash. Butter, which is a valuable food and an effective appetizer, should have a firm, waxy body, a pleasant, creamy flavour and should be delivered to the consumer in a pleasing package.

(E. S. G.)

**BUTTERCUP (RANUNCULUS BULBOSUS).** SHOWING TERMINAL FLOWERS AND BASE OF STEM SWOLLEN WITH STORED FOOD  
A. Leaf receptacle containing the mature seed  
B. Longitudinal section through flower  
C. Petal enlarged to show gland that secretes nectar, the chief source of the honey of bees

**BUTTER-AND-EGGS**, the name commonly given in the United States to the yellow toadflax (*q.v.*), widely naturalized from the Old World as a wayside weed. (See TOADFLAX.)

**BUTTERCUP**, a name given to various crowfoots which bear bright yellow, broadly cup-shaped flowers. Among the best known are the tall or meadow buttercup (*Ranunculus acris*), 2 ft. to 3 ft. high, with stiffly erect stems; the creeping buttercup (*R. repens*), which spreads by runners, and the bulbous buttercup (*R. bulbosus*), 1 ft. high, with the stem thickened at the base into a bulb. These plants, all natives of Northern Asia and Europe, and abundant in British Isles, have become widely naturalized in North America. Among the conspicuous native American species are the marsh buttercup (*R. septentrionalis*) and the California buttercup (*R. californicus*). See CROWFOOT; RANUNCULUS.

**BUTTER-FAT**, the fatty constituent of cows' milk. Butter, which is a solid emulsion containing fat, water, curd, milk-sugar and inorganic salts, is melted and allowed to settle; the clear butter-fat rises to the top and is separated by decantation. It does not become rancid as readily as butter, for the albuminous curd and the water present in the latter favour the growth of the organisms which promote rancidity. Butter-fat is chiefly manufactured in India and Egypt; before the war it was also prepared in Siberia (whence it was exported to Turkey), and to a less extent in Germany (Schmelzbutter). In India, where it is prepared in large quantities, butter-fat is known as "ghi"; it is commonly mixed with the milk-fat of the buffalo, while in Egypt the chief adulterants are the milk-fats of sheep and goats. In the latter country the fat is termed *Samna*. Butter-fat occupies a unique position among the natural animal fats because it contains considerable amounts of the glycerides of the water-soluble fatty acids—butyric, caproic, caprylic and capric acids. The Reichert-Meissel (Reichert-Wollny) value, which is a measure of the amount of these acids, is a valuable characteristic in butter-fat analysis. Especially characteristic is the presence of butyric acid, which is absent from coconut and palm-kernel oils, from which butter-fat is also distinguished by its smaller content of lauric acid. (See also OILS AND FATS.)

**BUTTERFIELD, DANIEL** (1831–1901), American soldier, was born in Utica, New York. He graduated at Union college in 1849 and when the Civil War broke out he became colonel of the 12th New York militia regiment. On May 14, 1861 he was transferred to the regular army as a lieutenant-colonel, and in September was made a brigadier-general U.S. volunteers. He served in Virginia in 1861 and in the Peninsular campaign of 1862; took part in the campaign of second Bull Run (Aug. 1862), became major-general U.S. volunteers, and in July 1863 Colonel U.S. army. After Gen. Hooker succeeded Burnside, Butterfield was appointed chief of staff, army of the Potomac, and served in the Chancellorsville and Gettysburg campaigns. He was sent as chief of staff to Hooker, with the XI. and XII. corps to Tennessee, and took part in the battle of Chattanooga (1863), and the Atlanta campaign of the following year. His services were recognized by the brevets of brigadier-general and major-general in the regular army. He resigned in 1870 to engage in civil and commercial pursuits. In 1862 he wrote a manual of *Camp and Outpost Duty* (1862). He died at Cold Spring, N.Y., on July 17, 1901.

A *Biographical Memorial*, by his widow, was published in 1904.

**BUTTERFIELD, WILLIAM** (1814–1900), English architect, was born in London, and educated for his profession at Worcester, where he laid the foundations of his knowledge of Gothic architecture. He settled in London and became prominent in connection with the Cambridge Camden Society, and its work in the improvement of church furniture and art. His first important building was St. Augustine's, Canterbury (1845), and his reputation was made by All Saints', Margaret Street, London (1859), followed by St. Alban's, Holborn (1863), the new part of Merton College, Oxford (1864), Keble College, Oxford (1875), and many houses and ecclesiastical buildings. He executed many restorations.

**BUTTERFISH**, a small fish, *Poronotus triacanthus*, caught along the Atlantic coast of the United States and sometimes known as the "dollar fish." The flavour is very delicate especially

when the fish is fried in butter until lightly browned. The name butterfish is also applied to various other fishes, particularly to species of blenny (*q.v.*) on account of the slippery nature of their bodies.

**BUTTERFLY** and **MOTH**, the common English names for insects forming the order Lepidoptera (*q.v.*).

**BUTTERFLY FISH**, the common name of the Chaetodonts, laterally compressed and often brilliantly coloured fishes of tropical seas, especially abundant in the vicinity of coral. (See *FISH*.)

**BUTTERFLY - WEED** (*Asclepias tuberosa*), a North American plant of the milkweed family (Asclepiadaceae), known also as pleurisy-root, orange-root and orange milkweed. It is native to dry fields, mostly in limestone soil, from Maine to Ontario and Minnesota and southward to Florida, Texas, Arizona and Chihuahua. The butterfly-weed is a stout, rough-haired perennial, with long horizontal roots. The usually erect, somewhat branching stem, 1 ft. to 3 ft. high, is very leafy throughout, and about midsummer bears numerous clusters of bright orange flowers. Unlike most milkweeds, this plant has a very scanty milky juice. The root has been used in medicine, especially for pulmonary affections. Butterfly-weed is often planted in wild gardens and is sparingly grown as a border plant.

BY COURTESY OF THE WILD FLOWER PRESERVATION SOCIETY  
**BUTTERFLY WEED, A NORTH AMERICAN FIELD PLANT BEARING ORANGE FLOWERS**

**BUTTERMILK**, the liquid residue after removing the butter from cream by the churning process. It consists mainly of water, some 90%, together with milk sugar, about 5%, and casein, about 3%. In addition it contains small quantities of butter fat and lactic acid. To the latter, which is formed during the ripening of the cream, buttermilk owes its slightly acid taste. In North America until about 1900 buttermilk was used chiefly for feeding pigs, especially in the leading dairy districts, but, owing to its healthful and nutritious qualities, it has since become widely popular as a beverage. In the United States and Canada it is extensively bottled for the market and sold at dairies, grocery stores, delicatessens, soda fountains and restaurants. In some sections, most of the buttermilk sold commercially is "cultivated." Certain bacteria are added to skimmed milk to produce fermentation. The resulting product is somewhat thicker than natural buttermilk, but is in other respect similar. (See *DAIRY*.)

**BUTTER-NUT**, the fruit of the North American white walnut (*Juglans cinerea*), a native of rich woods from New Brunswick to North Dakota and southward to Delaware, Georgia and Kansas. The nut is oblong with a hard, rough shell. The meat has a buttery flavour, pleasing to the taste when used in caramels or molasses candy. The name is applied also to the tree itself. Butter-nut is likewise the commercial name for the fruit of various species of the genus *Caryocarp* (fam. *Caryocaraceae*), native to South America, known also as souari-nut. (See *WALNUT*.)

**BUTTERWORT**, the popular name of a small insectivorous plant, *Pinguicula vulgaris*, which grows in wet, boggy land. It is a herb with a rosette of fleshy, oblong leaves, 1 to 3 in. long, appressed to the ground, of a pale colour, and with a sticky surface. Small insects settle on the leaves and are caught in the viscid secretion. This, like the secretion of the sundew and other insectivorous plants, contains a digestive enzyme which renders the nitrogenous substances of the body of the insect soluble and capable of absorption by the leaf. In this way the plant obtains nitrogenous food by means of its leaves. The leaves bear two sets of glands, the larger borne on usually unicellular stalks, the smaller

almost sessile. When a fly is captured, the viscid secretion becomes strongly acid and the naturally incurved margins of the leaf curve still further inwards, rendering contact between the insect and the leaf-surface more complete. The plant is widely distributed in the north temperate zone, extending into the arctic zone. In North America it ranges from the high northern tundras southward to Newfoundland, New York, Minnesota, Montana and British Columbia. The butterwort belongs to the bladderwort family (Lentibulariaceae) which comprises various other carnivorous plants. (See *BLADDERWORT*; *INSECTIVOROUS PLANTS*.)

**BUTTERFLY FISH**, SO NAMED BECAUSE OF ITS BRIGHT COLOURING

**BUTTERY**, a place for storing wine (O.Fr. *boterie*, Late Lat. *botaria*, a place where liquor is stored, from *butta*, a cask). Later, by confusion with "butter," a pantry or storeroom for food; at Oxford and Cambridge universities, especially, the place where food is kept.

**BUTTON**, a small piece of metal or other material which, pushed through a loop or buttonhole, serves as a catch between different parts of a garment, etc. The word is also used of other objects which have a projecting knob-like character, e.g., button-mushrooms, the button of an electric bell-push, or the guard at the tip of a fencing foil; or which resemble a button in size and shape, as the button of metal obtained in assaying operations. The derivation is from Fr. *bouton*, apparently from the same root as *bouter*, to push.

At first buttons were apparently used for purposes of ornamentation; in *Piers Plowman* (1377) mention is made of a knife with "botones ouergylte," and in Lord Berners's translation of *Froissart's Chronicles* (1525) of a book covered with crimson velvet with "ten botons of syluer and gylte." While this use has continued, especially in connection with women's dress, they began to be employed as fastenings at least as early as the 15th century. As a term of comparison for something trivial or worthless, the word is found in the 14th century. Buttons of distinctive colour or patterns, or bearing a portrait or motto, are often worn, especially in the United States, as a decoration, or sign of membership of a society or of adherence to a political party; among the most honoured of such buttons are those worn by members of the military order of the Loyal Legion of the United States, organized in 1865 by officers who had fought in the Civil War. Chinese officials during the Empire wore a button or knob on their hats as a mark of rank, the grade being denoted by its colour and material (see *MANDARIN*). Many varieties of buttons are used on clothing, but they may be divided into two main classes according to the arrangement by which they are attached to the garment; in one class they are provided with a shank which may consist of a metal loop or of a tuft of cloth or similar material, while in the other they are pierced with holes through which are passed threads. To these two classes roughly correspond two broad differences in the method of manufacture, according as the buttons are composite and made up of two or more pieces, or are simply shaped discs of a single material; some composite buttons, however, are provided with holes, and simple metal buttons sometimes have metal shanks soldered or riveted on them. From an early period buttons of the former kind were made by needlework with the aid of a mould or former, but about 1807 B. Sanders, a Dane who had been ruined

**BUTTERWORT, SHOWING THE FLOWER STEM GROWING OUT OF A ROSETTE OF GROUND LEAVES**

by the bombardment of Copenhagen, introduced an improved method of manufacturing them at Birmingham. His buttons were formed of two discs of metal locked together by having their edges turned back on each other and enclosing a filling of cloth or pasteboard; and by methods of this kind, carried out by elaborate automatic machinery, buttons are readily produced, presenting faces of silk, mohair, brocade or other material required to harmonize with the fabric on which they are used. Sander's buttons at first had metal shanks, but about 1825 his son invented flexible shanks of canvas or other substance through which the needle could pass freely in any direction. The mechanical manufacture of covered buttons was started in the United States in 1827 by Samuel Williston, of Easthampton (Mass.), who in 1834 joined forces with Joel and Josiah Hayden, of Haydenville.

**Buttons 140 Guineas a Gross.**—The number of materials that have been used for making buttons is very large—metals such as brass and iron for the cheaper kinds, and for more expensive ones, gold and silver, sometimes ornamented with jewels, filigree work, etc.; ivory, horn, bone, and mother-of-pearl or other nacreous products of shellfish; vegetable ivory and wood; glass, porcelain, paper, celluloid and artificial compositions; and even the casein of milk, and blood. Brass buttons were made at Birmingham in 1689, and in the following century the metal button industry underwent considerable development in that city. Matthew Boulton, the elder, about 1745, introduced great improvements in the processes of manufacture, and when his son started the Soho works in 1767 one of the departments was devoted to the production of steel buttons with facets, some of which sold for 140 guineas a gross. Gilt buttons also came into fashion about the same period. In this "Augustan age" of the Birmingham button industry, when there was a large export trade, the profits of manufacturers who worked on only a modest scale amounted to £3,000 and £4,000 a year, and workmen earned from £2 to £4 a week. At one time the buttons had each to be fashioned separately by skilled artisans, but gradually the cost of production was lessened by the adoption of mechanical processes, and instead of being turned out singly and engraved or otherwise ornamented by hand, they came to be stamped out in dies which at once shape them and impress them with the desired pattern. Ivory buttons are among the oldest of all. Horn buttons were made at Birmingham at least by 1777; towards the middle of the 19th century Emile Bassot invented a widely-used process for producing them from the hoofs of cattle, which were softened by boiling. Pearl buttons are made from pearl oyster shells obtained from various parts of the world, and after being cut out by tubular drills are shaped and polished by machinery. Buttons of vegetable ivory can be readily dyed. Glass buttons are especially made in Czechoslovakia, as also are those of porcelain, which were invented about 1840 by an Englishman, R. Prosser of Birmingham.

**The Birmingham Button Trade.**—The English button industry has always been centred in Birmingham, though considerable quantities are also manufactured in London. A large proportion of the industry is in the hands of a combine formed in 1907 by the amalgamation of several of the largest concerns. Rates of wages in the British industry are governed by a Trade Board that was established in 1920. In 1927, when an application was made by the British Button Manufacturers' Association for a duty on imports, it was stated that the industry was then carried on by 53 firms employing 3,629 people, whereas it was estimated that in 1913 the number of persons employed was about 6,850. Twelve of these 53 firms, it was said, were responsible for 85% of the total production, and the turnover of the whole trade was estimated at £750,000. Figures of production given by the manufacturers at the inquiry into their application for protection were, in gross, as follow: 1921, 4,300,000; 1922, 6,300,000; 1923, 5,700,000; 1924, 5,600,000; 1925, 6,200,000; 1926, 5,000,000. During the same years imports of buttons were, in gross: 1921, 4,474,000; 1922, 7,270,000; 1923, 6,966,000; 1924, 9,099,000; 1925, 10,645,000; 1926, 9,000,000.

All types of buttons are manufactured by English firms, but their principal output consists of linen, mother-of-pearl, composi-

tion, metal and fancy buttons. Germany, a big button manufacturing country, concentrates chiefly on fancy and Galalith buttons; France on mother-of-pearl and fancy metal; Italy on so-called vegetable ivory (the product of the corozo nut from South America); Japan on certain classes of mother-of-pearl; and Czechoslovakia on glass, china and paste (imitation precious stones). London is the centre of the world's trade in mother-of-pearl shells for buttons, which are brought from the Colonies (principally Australia) and auctioned in Mincing Lane in their raw state. They sell at anything from 80s. to 110s. per cwt., according to quality. These shells are distinct from the river mother-of-pearl which are used to make a cheaper class of button. Buttons are measured by the diameter, the unit being a "line." In all countries except France 10 lines are the equivalent of approximately  $\frac{1}{4}$  in. and sizes commence at 8 lines, rising in 2's to as much as 100 lines. Three French lines are the equivalent of 10 English. In the United States few buttons were made until the beginning of the 19th century, when the manufacture of metal buttons was started at Waterbury (Conn.), which became a centre of that industry. In 1812 Aaron Benedict began to make ivory and horn buttons at the same place. Buttons of vegetable ivory, now one of the most important branches of the American button industry, were first made at Leeds (Mass.), in 1859 by an Englishman, A. W. Critchlow, and in 1875 commercial success was obtained in the production of composition buttons at Springfield (Mass.). Pearl buttons were made on a small scale in 1855, but their manufacture received an enormous impetus in the last decade of the 19th century, when J. F. Boepple began, at Muscatine (Iowa), to utilize the unio or "niggerhead" shells found along the Mississippi.

By 1850, there were 59 United States button manufacturing concerns, using materials valued at \$324,837, the output being worth \$964,359. In 1919 the number of firms had risen to 57, producing buttons valued at \$41,840,000, and employing 15,600 persons. The United States, however, do not do a large export trade, being principally employed in meeting domestic requirements—or, rather, helping to meet them, for large quantities are also imported.

See *The Button Industry*, by W. Unite Jones; Sir Isaac Pitman and Sons, Ltd. (1924).

**BUTTON-BUSH** (*Cephalanthus occidentalis*), a North American shrub or small tree of the madder family (Rubiaceae), called also button willow and globe-flower. It grows in swamps and low grounds from New Brunswick to Minnesota southward to Florida and Texas, and also in California, Mexico and Cuba. In the northern parts of its range it is a shrub 3 ft. to 12 ft. high, but in southern Arkansas and eastern Texas it attains a height of 40 ft. to 50 ft., with a straight trunk a foot in diameter. It bears ovate, entire, pointed leaves and small, fragrant, creamy white flowers in globular stalked heads about an inch in diameter. In the north-eastern States the button-bush is sparingly cultivated as an ornamental plant.

**BUTTON SNAKEROOT** (*Liatris* or *Laciniaria*), a genus of North American plants of the family Compositae, comprising about 30 species found chiefly in the central and eastern United States and southern Canada. Various species, because of their showy flowers, are also called blazing star. They are erect, perennial, mostly unbranched herbs, with the stem usually rising from a globular tuber, whence the name *button* snakeroot. The leaves are narrow, often rigid, and sometimes strongly dotted; the rose-purple or rarely white flowers are borne in hemispherical or cylindrical heads, usually in long dense spikes or narrow racemes. Noteworthy examples are the scaly blazing star (*L. squarrosa*), 1 ft. to 2 ft. high, found from Ontario to South Dakota south to Florida and Texas; the handsome blazing star (*L. elegans*), 2 ft. to 3 ft. high, native to dry soil from Virginia to Arkansas and southward; the large button snakeroot (*L. scariosa*), sometimes 6 ft. high, found from Maine to Manitoba and southward to Florida and Texas; the dense button-snakeroot (*L. spicata*), called also gay-feather, colic-root and devil's-bit, 2 ft. to 6 ft. high, with blue-purple or white flowers, found from Massachusetts to Wisconsin and southward; and the prairie button

snakeroot (*L. pycnostachya*), 2 ft. to 5 ft., with very numerous rigid leaves and a long, very dense spike of purple flowers, native to prairies in the Mississippi valley.

**BUTTRESS**, a mass of masonry projecting from the face of a wall, either to strengthen the wall or to resist the side thrust of an arch, roof or vault abutting against that wall (*see* ABUTMENT). Until the extensive development of vaulting there was little need

DEVELOPMENT OF THE BUTTRESS FROM THE EARLY COLUMNAR TYPE TO THE FINAL GOTHIC FLYING BUTTRESS AND ONE MODERN TREATMENT

for buttresses, and therefore they are not found prior to the Roman period. In such buildings, however, as the great *thermae* of the Roman empire, the enormous vaults rendered careful buttressing a necessity. The Romans always attempted to combine their buttresses with necessary cross walls in the plan. Even when this could not be done and the buttresses showed externally (as in portions of the villa of Hadrian at Tivoli and the baths of Diocletian at Rome) no special architectural treatment was developed for them. Byzantine buttresses follow Roman precedent. In early Romanesque work buttresses occasionally occur as mere pilaster strips used largely for decorative purposes, and it was only with the rapid development of the vaulting of churches, in the 12th century, that buttresses of large size became necessary. Employed first around the apses of French churches these buttresses took form originally as engaged columns, complete with capital and base, and sometimes topped with a cone; then, as projecting masses of masonry with a steep slope at the top to shed the water. When naves came generally to be vaulted with ribbed and groined vaults, the tremendous concentration of thrusts at each bay rendered necessary an entirely new study of the buttress problem. The solution was only reached satisfactorily in the Gothic period. The Gothic builders seized upon this structural necessity and transformed it into one of their greatest opportunities for achieving architectural effect. The flying buttress (*q.v.*), the pinnacles which by weighting a buttress at its top increased its efficiency, the gables, and the moulded offsets all helped the buttress to function. In the later period of French

Gothic, sculpture was frequently added; in the late Gothic styles in all countries the tendency was towards over-elaboration and thinness. In modern work, due to the almost universal abandonment of structural vaults, buttresses are used only to strengthen thin walls as in retaining walls and the like, and are usually treated in the simplest manner possible. (T. F. H.)

**BUTURLINOVKA**, a town in the Voronezh province of the Russian Socialist Federal Soviet Republic, situated on the edge of a plateau, and on the branch railway to Kalach. Lat. 50° 48' N. Long. 40° 35' E. Pop. (1926) 27,548. It has sulphur mineral springs. It trades chiefly in cattle, and has tallow, tanning and leather factories. Its sheepskin coats and caps are noted.

**BUTYL ALCOHOLS**. Four isomeric alcohols of this formula,  $C_4H_9OH$ , are known; two of these are primary, one secondary and one tertiary (*see* ALCOHOLS). The two primary butyl alcohols arise during the high-pressure synthesis of methyl alcohol from carbon monoxide and hydrogen in presence of metallic catalysts (copper, cobalt, chromium, manganese, etc.). Normal butyl alcohol,  $CH_3(CH_2)_2CH_2OH$ , is a colourless liquid, boiling at 116.8°, and formed by reducing normal butyl aldehyde with sodium, or by a peculiar fermentation of glycerin, brought about by a schizomycete. The bacterial fermentation (*Bacillus butylicus*) of various carbohydrates yields *n*-butyl alcohol and acetone in the proportions 2:1 by weight. Isobutyl alcohol  $(CH_3)_2CHCH_2OH$ , the butyl alcohol of fermentation by yeast, is a primary alcohol derived from isobutane. It may be prepared by any of the general methods, and occurs in fusel oil, especially in potato spirit. It is a liquid, smelling like fusel oil and boiling at 108.4° C. Methyl ethyl carbinol,  $C_2H_5CH(CH_3)OH$ , is the secondary alcohol derived from *n*-butane. It is a strongly smelling liquid, boiling at 99°. Trimethyl carbinol or tertiary butyl alcohol  $(CH_3)_3COH$ , the simplest tertiary alcohol, was obtained by A. Butlerow in 1864 by acting with zinc methyl on acetyl chloride (*see* ALCOHOLS). It forms rhombic prisms or plates melting at 25° and boiling at 83°; it has a camphoraceous smell. Secondary butyl alcohol from butylene is obtained as a by-product from the petroleum cracking process (*see* PETROLEUM).

**BUTYRIC ACID** is the first acid in the acetic acid series to show structural isomerism (*q.v.*). There are two acids of the formula  $C_4H_7CO_2H$ . Normal butyric acid or fermentation butyric acid is found in butter, as an hexyl ester in the oil of *Heracleum giganteum*, as an octyl ester in parsnip (*Pastinaca sativa*), and in the oil of *Eucalyptus Perriniana* as *n*-butyl butyrate; it has also been noticed in meat juice, in perspiration and in excrements. The acid is an oily liquid of unpleasant smell, solidifies at -19° C., and boils at 162.3° C. It is easily soluble in water and alcohol, and is thrown out of aqueous solution by calcium chloride. The calcium salt,  $Ca(C_4H_7O_2)_2 \cdot H_2O$ , is less soluble in hot water than in cold. It may be synthesised by hydrolysing ethylacetoacetic ester (*see* CHEMISTRY: Organic, [1] Aliphatic). It is ordinarily prepared by the fermentation of sugar or starch, brought about by the addition of putrefying cheese, calcium carbonate being added to neutralize the acids formed in the process. A. Fitz (b. 1878) found that the butyric fermentation of starch is aided by the direct addition of *Bacillus subtilis* (hay bacillus).

*Isobutyric acid*,  $(CH_3)_2CHCOOH$ , is found in the free state in carobs (*Ceratonia siliqua*) and in the root of *Arnica dulcis*, and as an ethyl ester in croton oil. It is a liquid of somewhat unpleasant smell, boiling at 155.5° C. It may be artificially prepared by the hydrolysis of isopropylcyanide with alkalis, by the oxidation of isobutyl alcohol with potassium bichromate and sulphuric acid (I. Pierre and E. Puchot, 1873), or by hydrolysing dimethylacetoacetic ester (*cf. supra*). Alkaline potassium permanganate oxidizes it to  $\alpha$ -hydroxyisobutyric acid,  $(CH_3)_2C(OH)COOH$ , whilst concentrated nitric acid converts it into dinitroisopropane. Its salts are more soluble in water than those of the normal acid, the calcium salt differing from its normal isomeride in being more soluble in hot than in cold water.

**BUXAR** or **BAXAR**, a sub-divisional town of northeastern India, in the Shahabad district of Bêhar and Orissa, Bengal, on the south bank of the Ganges, with a station on the East Indian Railway. Pop. (1921) 10,098. There is a dismantled fort of

small size which was important from its commanding the Ganges. A celebrated victory was gained here on Oct. 23, 1764, by the British forces under Major (afterwards Sir Hector) Munro, over the united armies of Shuja-ud-Dowlah and Kasim Ali Khan. The action raged from 9 o'clock till noon, when the enemy gave way. Pursuit was, however, frustrated by Shuja-ud-Dowlah sacrificing a part of his army to the safety of the remainder. A bridge of boats had been constructed over a stream about 2m. distant from the field of battle, and this the enemy destroyed before their rear had passed over. Through this act 2,000 troops were drowned, or otherwise lost; but destructive as was this proceeding, it was, said Maj. Munro, "the best piece of generalship Shuja-ud-Dowlah showed that day, because if I had crossed the rivulet with the army, I should either have taken or drowned his whole army in the Karamnasa, and come up with his treasure and jewels, and Kasim Ali Khan's jewels, which I was informed amounted to between two and three millions."

See C. E. A. W. Oldham, "The Battle of Buxar," *Journal of Bihar and Orissa Research Society* (1926).

**BUXTEHUDE, DIETRICH** (1637-1707), organist and composer, was born at Helsingborg, Sweden, the son of Johann Buxtehude (d. 1674), who was for over 30 years organist of the Olai church at Helsingör, Denmark. Dietrich studied under his father, and in 1668 was appointed organist of the Marienkirche, Lübeck, where he instituted the famous *Abendmusiken*, sacred concerto held in the church during Advent each year, which J. S. Bach walked 50 miles to attend. Buxtehude was one of the most eminent musicians of his day and a composer of real note who had considerable influence upon the earlier writings of Bach. His organ works were edited (2 vols., 1876-78) by Spitta, and some of his cantatas by M. Seiffert in *Denkmäler deutscher Tonkunst* (1904).

See A. Pirro, *Dietrich Buxtehude* (1913).

**BUXTON, SIR THOMAS FOWELL** (1786-1845), English philanthropist, was born at Earl's Colne, Essex, on April 1, 1786, and was educated at Trinity College, Dublin. In 1807 he married Hannah Gurney, sister of Elizabeth Fry. He entered in 1808 the brewery of Truman, Hanbury & Company, of which his uncles, the Hanburys, were partners. He became a partner in 1811, and soon had the whole concern in his hands. In 1816 he made a famous speech on behalf of the Spitalfields weavers, and in 1818 he published his able *Inquiry into Prison Discipline*. The same year he was elected M.P. for Weymouth, a borough he represented till 1837. In the House of Commons Buxton worked for the abolition of slavery in British colonies, but when success came in 1833 he was compelled to admit into the bill some clauses against which his better judgment had decided. He travelled on the continent in 1839 to recruit his health, which had given way, and took the opportunity of inspecting foreign prisons. He was made a baronet in 1840, and then devoted himself to a plan for ameliorating the condition of the African natives. The failure of the Niger expedition of 1841 was a blow from which he never recovered. He died on Feb. 19, 1845.

See *Memoir and Correspondence of Sir T. F. Buxton* (1848), by his third son, Charles Buxton (1823-71).

**BUXTON**, municipal borough and health-resort, north Derbyshire, England, on the L.M.S. railway, 36 m. N.W. of Derby. Pop. (1931) 15,353. It is in the centre of the Peak District, and has the reputation of being the highest town in England. It lies between 1,000 and 1,150 ft. above sea-level, in a basin protected by hills of grit and limestone rising to 1,800 ft., whence flows the river Wye on the south-east. The old town (High Buxton) is at a higher level than the new, and consists of one wide street. The mineral waters of Buxton are tasteless and odourless, and have long enjoyed a great reputation. The waters were known and used by the Romans, but no remains of their baths survive. Roman roads connected the place with Derby, Brough in Edale and Manchester. Buxton (Bawdestanes, Bue-stanes) was probably the "Bectune" mentioned in Domesday. After the departure of the Romans the baths seem to have been long neglected, but have again been frequented since the 16th century, when the chapel of St. Anne acquired fame for the

"cures" effected. At the close of the 18th century the duke of Devonshire, lord of the manor, spent large sums of money on improvements in the town. There are numerous public and private baths, open all the year round, for the treatment of nervous diseases, gout, rheumatism, etc. The waters are of two distinct classes: thermal and chalybeate. The thermal waters issue at a constant temperature of 82° F. The Pump Room, presented by the duke of Devonshire, contains both thermal and chalybeate springs. Features of note in the town are the Buxton Gardens and the Cavendish Terrace. In the neighbourhood are Poole's Hill, a stalactite cave; Diamond Hill, so called from the quartz crystals in its rocks; and Chee Tor, a 300 ft. cliff on the bank of the Wye. Buxton is an important centre for horse-breeding, a large fair being held annually. A Saturday market was granted in 1813. The busiest season at Buxton is from May to October, but the bracing air, low humidity and winter sports ensure growing popularity as a winter resort. The town was made a municipal borough on Jan. 1 1917. It is governed by a mayor, and corporation of 24 members. Area 3,101 acres. For purposes of representation it is included in the High Peak division of the parliamentary county of Derby.

**BUXTORF or BUXTORFF, JOHANNES** (1564-1629), German Hebrew and Rabbinic scholar, was born at Kamen in Westphalia. At the instance of Grynaeus, he undertook the duties of the Hebrew chair in the University of Basle, and after two years was unanimously appointed to the vacant office. From this date (1591) to his death he remained in Basle, and devoted himself to the study of Hebrew and rabbinic literature. He received into his house many learned Jews, that he might discuss his difficulties with them, and he was frequently consulted by Jews themselves on matters relating to their ceremonial law. On one occasion this brought him into trouble with the authorities of the city, but, on the whole, his relations with the city of Basle were friendly. He corresponded with the most distinguished scholars of the day; the library of the University of Basle contains a collection of letters, which are valuable for a literary history of the time.

WORKS.—*Manuale Hebraicum et Chaldaicum* (1602; 7th ed., 1658); *Synagoga Judaica* (1603 in German; afterwards enlarged and translated into Latin), a valuable repository of information regarding the opinions and ceremonies of the Jews; *Lexicon Hebraicum et Chaldaicum cum brevi Lexico Rabbinico Philosophico* (1607; reprinted at Glasgow, 1824); his great rabbinical Bible, *Biblia Hebraica cum Paraphr. Chald. et Commentariis Rabbinorum* (1618; 1618-19).

BIBLIOGRAPHY.—For additional information regarding his writings see *Athenae Rawicae*, p. 444-448; articles in Ersch and Gruber's *Encyklopädie*, and Herzog-Hauck, *Realencyk.*; J. P. Nicerson's *Mémoires*, vol. xxxi., p. 206-215; J. M. Schroeck's *Kirchengeschichte*, vol. v. (Post-Reformation period), p. 72 seq. (Leipzig, 1806); G. W. Meyer's *Geschichte der Schrift-Erklärung*, vol. iii. (Göttingen, 1804); and E. Kautsch, *Johannes Buxtorf der Ältere* (1879).

**BUXTORF or BUXTORFF, JOHANNES** (1599-1664), son of the preceding, concentrated on theological and Semitic studies, and in 1622 published at Basle a *Lexicon Chaldaicum et Syriacum*, as a companion work to his father's great Rabbinical Bible. On the death of his father in 1629, he was unanimously designated his successor in the Hebrew professorship at Basle, where he remained till his death. In 1647 a third theological professorship was founded specially for him, but when the professorship of the Old Testament became vacant in 1654, Buxtorf accepted that chair instead.

Much of Buxtorf's public life was spent in controversy on biblical criticism. The Reformed churches at this time, having renounced the dogma of an infallible church, thought it necessary to maintain that of an infallible Bible and, as the necessary foundation of this, of a Bible handed down from the earliest ages without textual alteration. Even the vowel points and accents were held to have been given by divine inspiration. The Massoretic text of the Old Testament, therefore, as compared with that of the Samaritan Pentateuch, the Septuagint or the Vulgate, alone contained the true words of the sacred writers. Although many of the Reformers, as well as learned Jews, had long seen that these views could not be made good, there had been as yet no formal controversy. Louis Cappel (*q.v.*) was the first to dispel

these illusions by a work on the modern origin of the vowel points and accents, published anonymously in 1624, under the title *Arcanum Punctuationis revelatum*. In 1648 Buxtorf published his *Tractatus de punctorum origine, antiquitate, et autoritate, oppositus Arcano punctuationis revelato Ludovici Cappelli*. He tried to prove by citations from the rabbinical writers, and by various arguments, that the points were at least as old as the time of Ezra, and thus possessed the authority of divine inspiration. Cappel replied in a second edition, which, however, was not published until 1685. Buxtorf engaged in three other controversies with the same antagonist, on the subject of the integrity of the Massoretic text of the Old Testament, on the antiquity of the present Hebrew characters, and on the Lord's Supper.

Besides the works mentioned in this article, Buxtorf edited the great *Lexicon Chaldaicum, Talmudicum, et Rabbinicum*, on which his father had spent 20 years, and the great Hebrew *Concordance*.

**BUYER**, one who purchases or acquires by barter. The individual buyer purchases commodities for himself through the expenditure of his own money, or its equivalent. As commonly used, however, the term refers to the authorized purchasing agent for some other individual, firm or institution. On the stock exchange, the buyer or broker is an individual or a firm legally invested with the power of buying stocks and bonds upon order from the purchaser.

The term "buyer" in business parlance, refers usually to an individual buying for the retail and wholesale trade. Large department stores are composed of a great number of departments, each specializing in a given line of commodities. Each of these departments is headed by a buyer, that is, a man or woman employed by the store owner, to buy on the market such articles as are required to keep the department running. The department store buyer differs from a stock exchange broker in that all the buying of the former is done on the department store's credit, the buyer serving as an intermediary between the manufacturer and the store-keeper. Invested with the right of buying what he considers his store's clientèle demands, he selects his goods and instructs the manufacturer from whom he buys to submit the bill directly to the store owner. He is responsible for seeing that the merchandise he buys is fresh and strong in selling appeal. It is his duty to select the best quality at the lowest possible price, and to undersell corresponding departments in other stores, whenever possible. In the highly organized systems of operation recently adopted by the larger and more progressive department stores a merchandise manager is put in charge of three or four kindred departments. Such a manager is responsible for the profit and loss figures of the departments under his control. The buyer, however, is still the active purchasing agent for his particular department, and his relationship to the merchandise manager is one of co-worker, rather than subordinate.

**BUYER'S OPTION**, a written contract under the terms of which a buyer of securities need not accept delivery until the end of a specified time but may demand delivery at any time within the limit upon one day's notice. On the New York Stock Exchange a buyer's option must be for a term of not less than 4 nor more than 60 days. The buyer, unless the contract is "flat" (without interest), pays the seller interest on the price of the security at the legal rate up to the date of delivery.

**BUYING IN**. On the London stock exchange, a transaction by which, if a member has sold securities which he fails to deliver on settling day, or any of the succeeding 10 days following the settlement, the buyer may give instructions to a stock exchange official to "buy in" the stock required. The official announces the quantity of stock, and the purpose for which he requires it, and whoever sells the stock must be prepared to deliver it immediately. The original seller has to pay the difference between the two prices, if the latter is higher than the original contract price. A similar practice, termed "selling out," prevails when a purchaser fails to take up his securities. (See STOCK EXCHANGE.)

**BUYS BALLOT'S LAW**, in meteorology, the name given to a law which may be expressed as follows:—"Stand with your back to the wind; the low-pressure area will be on your left-hand." This rule, the truth of which was first recognized by the

American meteorologists J. H. Coffin and W. Ferrel, is a direct consequence of Ferrel's Law (*q.v.*). It is approximately true in the higher latitudes of the northern hemisphere, and is reversed in the southern hemisphere, but the angle between barometric gradient and wind is seldom a right angle in low latitudes. The law takes its name from C. H. D. Buys Ballot, the chief of the Dutch Meteorological Services from 1854-89, who introduced a new instrument called the aeroclinoscope which indicated the position of the centre of a depression and the barometric gradient. The original formulation of the law was modified later, but an early form of it appears in the *Jaarboek* of the Meteorological Institute of the Netherlands for 1857.

**BUYSSE, CYRIEL** (1859- ), Flemish writer, published his first book in 1893. In his portrayal of the lives and people of eastern Flanders he is a follower of the French naturalists. There is no writer of fiction who shows us with more realism every aspect of the Flemish people. He is an excellent story-teller, not without humour, and with his virile art and sober yet vivid style he knows well how to accentuate the essential characteristics of men and things never losing sight of their natural environment. He has written over 40 novels and short stories.

**BUZĂU**, a town of Rumania, capital of the department of the same name, situated near the right bank of the river Buzău, between the Carpathian mountains and the fertile lowlands of south Moldavia and east Walachia. Pop. (1924) 32,000. Buzău is important as a market for petroleum, timber and grain. It is the meeting-place of railroads from Ramnicu Sarat, Brăila and Ploesti. Amber is found by the riverside, and there are cloth-mills in the city. Buzău is the seat of a bishop, whose cathedral was erected in 1640 by Prince Matthias Bassarab of Walachia, on the site of an older church. In the neighbourhood there are many monasteries. Buzău was formerly called Napuca or Buzograd. The department of Buzău is rich in oil, and produces some lignite.

**BUZOT, FRANÇOIS NICOLAS LEONARD** (1760-1794), French revolutionist, at the outbreak of the Revolution was an advocate in his native town (Evreux). In 1789 he was elected deputy to the States-General, and there became known for his advanced opinions. In 1792 he was elected deputy to the convention, and took his place among the Girondists. He demanded the formation of a national guard from the departments to defend the convention against the populace of Paris. His proposal was carried, but never put into force; and the Parisians were extremely bitter against him. Proscribed with the Girondists on June 2 1793, he took refuge in Normandy, where he contributed to organize a federalist insurrection against the Convention, which was speedily suppressed. Buzot was outlawed, fled, and committed suicide in the woods of St. Émilien on June 18 1794.

See *Mémoires de Pétion, Barbaroux, Buzot*, published by C. A. Daubon (1866).

**BUZULUK**, a town in the Samara Province of the Russian Socialist Federal Soviet Republic, situated on the left bank of the Samara river near its junction with the Buzuluk and Domashke. Lat. 52° 48' N., long. 52° 12' E. Pop. (1926) 24,562, mainly Russians and Mohammedan Tatars. It is on the railway, has telegraphic connection with the south and is a river port with an elevator. It trades chiefly in corn and cattle, and has tallow, soap, leather, brick and oil pressing (from sunflower seed) industries. Its position on the northern edge of the dry steppe area makes it liable to famine, from which it suffered in 1921.

**BUZZARD**, a bird of prey. The buzzards are distinguished from the eagles by their bill, which is decurved from the base. The head, too, in buzzards is short and round, while in the eagles it is elongated. In a general way buzzards are smaller than eagles, and have their plumage more mottled. Furthermore, most if not all of the buzzards assume their adult dress at the first moult, while the eagles take longer to reach maturity. The buzzards are fine looking birds, but are slow and heavy of flight. Their food consists of small mammals, young birds, reptiles, amphibians and insects. Buzzards are found over the whole world with the exception of the Australian region. In the British Isles are two species, one resident (*Buteo buteo*) and now confined to a few

wooded districts; the other, the rough-legged buzzard (*B. lagopus*), a somewhat irregular winter visitant. The honey-buzzard (*Pernis apivorus*), a summer visitor from the south, and breeding, or attempting to breed, yearly in the New Forest, is the type of a distinct genus of which there are other examples in Africa and Asia. In America the name "buzzard" is popularly given to the turkey-buzzard or turkey-vulture (*Cathartes aura*). There are also several species of the genus *Buteo* in North America: the red-tailed hawk (*B. borealis*), and red-shouldered hawk (*B. lineatus*), with eastern and western forms; and Swainson's hawk, in the western states.

**BYBLOS:** see JEBAIL.

**BYELAYA TSERKOV** (White Church), a town in the Ukrainian Socialist Soviet Republic, on the left bank of the Rosi river, on a branch railway and on the main road from Kiev to the Crimea. Lat. 49° 50' N., Long. 30° 8' E. Pop. (1926) 21,939. It has an elevator and a radio station, trades in cattle and grain, and has numerous fairs. It is first mentioned in 1155, but was destroyed by the Mongols in the 13th century. In 1550 the Prince of Kiev built a castle here and gave the inhabitants various privileges. From 1651 it was subject alternately to Poland and to independent hetmans (Cossack chiefs), but became Russian after 1793.

**BYELEV**, a town in the province of Tula in the Russian Socialist Federal Soviet Republic, on the left bank of the Oka river. Lat. 53° 48' N., Long. 36° 9' E. Pop. (1926) 12,794. It has an annual fair trading in grain, hemp, oil, cattle and tallow, and has tallow, oil, tanning, sugar refining and distilling industries. It is first mentioned in 1147, belonged to Lithuania at the end of 14th century and in 1468 became a principality dependent on Lithuania. At the end of the 15th century it began to attach itself to the Grand-duchy of Moscow and was united to Russia by Ivan III. It was repeatedly attacked by the Tatars in the 16th century. The Empress Elizabeth died here whilst going from Taganrog towards Leningrad. Its public library (1858) is a memorial to the poet Zhukovsky, who was born in 1782 in a neighbouring village.

**BYELGOROD** (White Town), a town in the Kursk province of the Russian Socialist Federal Soviet Republic, on a chalk hill on the right bank of the Donetz river. Lat. 50° 38' N., Long. 36° 37' E. Pop. (1926) 22,794. It is a railway junction and has a radio station. It is situated near a patch of timber-bearing land and trades in honey, wax, leather, grain and cattle, and has lime and brickworks. It became an archiepiscopal see in 1666, and its two cathedrals and its theological college date from the 16th century. In the 17th century it was frequently attacked by Tatars, and an earthen wall, with 12 forts, called the Byelgorod line, was built across the 200m. between the Vorskla river and the Don river.

**BYELUY, ANDREI** (1880— ), pen name of Boris Bugaiev, Russian writer, was born in Moscow, Oct. 7, 1880, the son of a well-known mathematician. When he graduated in 1904 from the Moscow university, he had already published poetry of a symbolic type. His books of poetry and rhythmic prose are symbolic phantasies, in essence spiritual, yet expressed in realistic images. The most famous of these are: *Gold in Blue* (1904), *Ashes* (1909) and *The Urn* (1909). His prose is best represented in three novels: *The Silver Dove* (1910), a psychological study of Russian religious sects, reminiscent of Gogol; *Petersburg* (1916), a gloomy, fantastic tale about Russian pre-revolutionary realities; *Kotik Letaiiev* (1922), an imaginative autobiography—the problems of life and the mind, seen through the soul of a child. One of the most remarkable of his later books is *The Reminiscences of A. Blok*.

**BYEZHETSK**, a town in the Tver province of the Russian Socialist Federal Soviet Republic, on the right bank of the Mologa river. Lat. 57° 48' N., Long. 36° 39' E. Pop. (1926) 12,236. It is on a railway, and has a radio station. Its scythes, agricultural implements and hardware are noted and it also trades in grain, linen, hemp and flax. It is mentioned in the chronicles of 1137 and, on the fall of Novgorod, to which it had belonged; it was incorporated, in 1479, with the Moscow Grand-Duchy.

**BY-LAW** or **BYE-LAW**, either (1) a regulation made by a common law corporation, one of the legal incidents of which is the power to make regulations for the government of its members, or (2) a regulation made by a statutory corporation which, unlike the former, has no power to make such regulations unless it is expressly conferred upon it. Thus a municipal corporation, which is always a common law corporation created by charter, has an inherent power to make such by-laws, while a statutory corporation, a term which includes both county councils and railway companies, always has its powers defined by statute. The power of town councils to make such regulations is, however, now defined and extended by the Municipal Corporation Act of 1882, while various general acts, such as the Public Health Act of 1875, had already given them and other Public Health authorities the power to make by-laws for the particular purpose of those acts.

It is a rule of law that when the power to make by-laws exists, whether at common law or by statute, its existence imports the power to enforce the by-law by penalties, but obedience to it cannot be enforced by the imprisonment of the offender; the only penalty is a pecuniary one, i.e., the infliction of a fine or the recovery by action of a money penalty (see *Hall v. Nixon*, 1875, L.R. 10 Q.B. 159). It is usual, however, for any statute giving power to make by-laws to incorporate by reference the Summary Jurisdiction Acts, in which case the offender against the by-law is, in default of a fine, liable to imprisonment. County councils are expressly given by s. 16 of the Local Government Act of 1888 the same power of making by-laws in relation to their county as the council of a borough have in relation to their borough. There is an important difference between statutory rules and orders (*q.v.*) and by-laws, in that the latter, unlike the former, can be quashed by the courts, even when they are otherwise *intra vires*, on the mere ground that they are "unreasonable," i.e., oppressive or in conflict with the common law. The courts have further laid it down (*Salt v. Scott Hall*, 1903, K.B. 245) that even though a by-law may be reasonable in its general operation and therefore not to be quashed as such, the subject is protected against its oppressive enforcement in a particular case by the rule that the magistrates are not bound to convict in every case of infringement of a by-law that comes before them. The magistrates have power under s. 16 of the Summary Jurisdiction Act of 1879, if they think the circumstances warrant such a course, to dismiss the summons.

There is another check upon the abuse of the power of making by-laws, viz., the superior power of a central department to "disallow" them. The by-laws of a county council require the assent of the Ministry of Health; the by-laws of a municipal corporation may be disallowed by the king on the advice of the Privy Council. This, however, is a negative power, and the fact that a Government department has not disallowed a by-law, or has approved it, in no way deprives the courts of the power to pronounce it unreasonable. The by-laws of railway companies require the approval of yet another Government department, the Board of Trade.

The courts have laid down the important principle that in the exercise of their power to declare a by-law "unreasonable" they will extend more latitude to the interpretation of by-laws made by local authorities than to that of by-laws made by "profit-making companies," which latter "the courts must scrutinize jealously" (see *Kruse v. Johnson*, 1898, 2 Q.B.) 91, which may now be regarded as the leading case on the subject). In that case the court held that the by-law of a local authority "ought to be supported unless it was manifestly partial and unequal in its operation between different classes, or unjust, or made in bad faith, or clearly involving an unjustifiable interference with the liberty of those subject to it." The Interpretation Act of 1889 enacts that a statutory power to make by-laws includes a power to rescind, revoke, amend and vary them, a fact which, as the court observed in that case, means that a local authority can always, under the pressure of the public opinion of the locality, be compelled to alter them if they are unpopular or unnecessary. Furthermore, the Municipal Corporation Act of 1882 has interposed certain safeguards in the exercise of this legislative function

such as the requirement of a two-thirds majority of the council and of 40 days notice to the burghesses. By-laws may therefore be regarded as a class of "subordinate" or "delegated" legislation which is wholly free from the oppressive and arbitrary character which too often attaches to the legislative activities of Government departments, invested by statutes of their own devising with the power to make "statutory orders" having the full force of a statute and, as such, uncontrollable by the courts of law.

(J. H. Mo.)

**United States.**—In America the term by-law refers to the rules made by a private corporation for the regulation of corporate affairs. Their binding force is derived from mutual assent, either express or implied, on the part of the members. Non-members and non-assenting members are not subject to them. Usually the power to make by-laws is specifically granted in the charter, which may also expressly limit the scope, application, use and purpose of such corporate legislation. Ordinarily, special persons, such as the directors, are vested with the power of making by-laws. Where this is not done, power lies in the members-at-large. In contradistinction to the British usage, the term by-law does not include municipal ordinances.

**BYLES, MATHER** (1706–88), American clergyman, was born in Boston (Mass.), March 26 1706, and was descended, on his mother's side, from John Cotton and Richard Mather. He was graduated at Harvard in 1725, and in 1733 became pastor of the Hollis Street church (Congregational), Boston. He was noted for his scholarly sermons and his ready wit, and he and his friend Joseph Green were prominent figures in what was one of the most barren periods in American poetry. A Tory during the Revolution, he was tried by his church and in 1777 by the civil authorities, who sentenced him to deportation. This sentence was later changed to imprisonment in his own house. He was soon released, but never resumed his pastorate. He died in Boston July 5 1788. Besides many sermons, he published various short pieces, such as "The Conflagration" (1729) and a collection of verse, *Poems on Several Occasions* (1744).

See A. W. H. Eaton, *The Famous Mather Byles* (1914).

**BYNG, JOHN** (1704–1757), British admiral, was the fourth son of George Byng, Lord Torrington, and entered the navy in 1718. On the approach of the Seven Years' War the island of Minorca was threatened by an attack from Toulon and was actually invaded in 1756. Byng, who was then serving in the Channel with the rank of admiral, which he attained in 1755, was ordered to the Mediterranean to relieve the garrison of Fort St. Philip, which was still holding out. The squadron was not very well manned, and Byng was in particular much aggrieved because his marines were landed to make room for the soldiers who were to reinforce the garrison, and he feared that if he met a French squadron after he had lost them he would be dangerously undermanned. His correspondence shows clearly that he left prepared for failure, that he did not believe that the garrison could hold out against the French force landed, and that he was already resolved to come back from Minorca if he found that the task presented any great difficulty. He wrote home to that effect to the ministry from Gibraltar. The governor of the fortress refused to spare any of his soldiers to increase the relief for Minorca, and Byng sailed on May 8. On the 19th he was off Minorca, and endeavoured to open communications with the fort. Before he could land any of the soldiers, the French squadron appeared. A battle was fought on the following day. Byng, who had gained the weather gauge, bore down on the French fleet of M. de la Galissonnière at an angle, so that his leading ships came into action unsupported by the rest of his line. The French cut the leading ships up, and then slipped away. When the flag captain pointed out to Byng that by standing out of his line he could bring the centre of the enemy to closer action, he declined on the ground that Thomas Mathews had been condemned for so doing. The French, who were equal in number to the English, got away undamaged. After remaining near Minorca for four days without making any further attempt to communicate with the fort or sighting the French, Byng sailed away to Gibraltar leaving Fort St. Philip to its fate. The failure

caused a savage outburst of wrath in the country. Byng was brought home, tried by court-martial, condemned to death, and shot on March 14, 1757 at Portsmouth. The severity of the penalty, aided by a not unjust suspicion that the ministry sought to cover themselves by throwing all the blame on the admiral, led in after time to a reaction in favour of Byng. It became a commonplace to say that he was put to death for an error of judgment. The court has indeed acquitted him of personal cowardice or of disaffection, and only condemned him for not having done his utmost. But it must be remembered that in consequence of many scandals which had taken place in the previous war the Articles of War had been deliberately revised so as to leave no punishment save death for the officer of any rank who did not do his utmost against the enemy either in battle or pursuit. That Byng had not done all he could is undeniable, and he therefore fell under the law. In 1745 an unhappy young lieutenant, Baker Phillips by name, whose captain had brought his ship into action unprepared, and who, when his superior was killed, surrendered the ship when she could no longer be defended, was shot by sentence of a court-martial. This savage punishment was approved by the higher officers of the navy, who showed great lenity to men of their own rank. The contrast had angered the country, and the Articles of War had been amended precisely in order that there might be one law for all. The facts of Byng's life are fairly set out in Charnock's *Biogr. Nav.* vol. iv. pp. 145 to 179. The number of contemporary pamphlets about his case is very great, but they are of no historical value, except as illustrating the state of public opinion.

(D. H.)

**BYNG, JULIAN HEDWORTH GEORGE BYNG**, 1ST VISCOUNT (1862– ), British general, was born Sept. 11, 1862, son of the 2nd earl of Strafford, and joined the 10th Hussars in India in 1883. He passed through the Staff college, and served in the South African War. In 1912 he was sent to Egypt to take command of the army of occupation. In Oct. 1914 he took the 3rd Cavalry Division to France, and he succeeded to command of the Cavalry Corps in June 1915. But two months later he was despatched to the Dardanelles to take charge of the IX. Army Corps there and he became responsible for the Suvla area, from which he withdrew his troops most skilfully in the following December. Called back to the Western Front, in May 1916, he took over the Canadian Army Corps, a tenure distinguished by the capture of Vimy Ridge on April 9, 1917. In June 1917 he succeeded to the leadership of the III. Army, which he retained till the close of the war. On Nov. 20 he carried out the now famous tank surprise attack on the Cambrai front. In Oct. 1919 he received a barony and a grant of £30,000. In June 1921 he was appointed Governor-General of Canada, retaining the position until 1926 in which year he was created a viscount. In July 1928 he was appointed Commissioner of the Metropolitan Police.

**BYNKERSHOEK, CORNELIUS VAN** (1673–1743), Dutch jurist, was born at Middelburg, Zeeland. He studied law at Franeker, Friesland, and was called to the bar at The Hague. In 1703 he was appointed a member of the supreme court of Holland and Zeeland, of which in 1724 he became president. In that position he enjoyed very great prestige, but his judicial career did not prevent him from publishing a large and varied number of works of legal scholarship. His writings on Roman and Dutch municipal law are important, but his fame rests chiefly on what he did for the development of international law on positive lines. To a greater extent than any of his predecessors in this field he took actual usage, as appearing from ordinances issued by the States General or other Governments and from treaties concluded between Christian States as the basis of his studies. On questions like the sovereignty of the seas, the legal position of ambassadors, private property in war time, prizes, neutrality, contraband, blockade, his opinions have always been regarded as carrying great weight and have exercised considerable influence.

**BIBLIOGRAPHY.**—Bynkershoek's principal works in the domain of international law are *De Dominio Maris* (1702), *De Foro Legatorum* (1721), *Quaestiones juris Publici* (1737). Complete editions of his works were published after his death, one at Geneva in 1761, and another at Leiden in 1766. See O. W. S. Numan, *Cornelis van*

*Bynkershoek* (Leiden, 1869); J. Delpech, in *Les fondateurs du droit international* (1904); Coleman Philipson, in *Journal of the Society of Comparative Legislation* (1908).

**BYRD, RICHARD EVELYN** (1888– ), American naval officer and aeronautic explorer, was born in Winchester, Va., on Oct. 24, 1888. He was educated at the Shenandoah Valley academy, Winchester, and at the age of 12 made a trip round the world unaccompanied. He attended the Virginia military institute from 1904–07 and the University of Virginia, 1907–08. Entering the U.S. Naval Academy in 1908, he graduated in 1912. During the World War he held the temporary rank of lieutenant-commander in command of the U.S. naval forces operating in Canadian waters, and built up the naval aviation stations at North Sidney and Halifax, N.S. He was appointed lieutenant in 1918, and was promoted lieutenant-commander on the retired list by special Act of Congress in 1922. In 1925 he went to Greenland as flight commander with the Macmillan expedition under the auspices of the National Geographic Society. The experience there gained convinced him that a flight to the North Pole was feasible if undertaken in the month of May. On his return he selected a carefully tested Fokker monoplane equipped with three Wright air-cooled motors. He left New York city in April, 1926 and Spitsbergen was reached without mishap. Accompanied only by his pilot, Floyd Bennett, he started from Spitsbergen at 12:50 A.M. on May 9, 1926, having two objectives, a flight to the Pole (680m. distant) and back and alternatively a flight to Peary Land. Taking off from King's Bay, Amsterdam island, he flew in a straight line to the Pole, which he reached and circled around several times, incidentally verifying the observations of Admiral Peary in 1909. Returning, his course was to Verlegen Hook, New Friesland, thence west to his starting point, which he reached at 4:20 P.M. His flying time was 15½ hours and the total mileage covered was 1,600.

On June 29–July 1, 1927, Byrd made a dramatic four-passenger flight from New York to Ver-sur-Mer, France, covering an airline distance of 3,744m. in 46 hours and six minutes. Upon reaching the European mainland he encountered heavy fog and rain. After circling blindly for hours over inland France, he was compelled to descend to the ocean, near the shore line, after a total flight of about 4,200m. In making this perilous landing his powerful tri-motored monoplane was wrecked, but, largely through his skill, the party reached shore uninjured. Early in 1928 he published *Skyward*, an account of his experiences in aviation, and organized an expedition, which set off later in the same year, equipped for two years' aeronautical exploration of the Antarctic continent, including a flight to the South Pole.

Byrd established his base to the south of New Zealand, in the neighborhood of 165° W., and named it Little America. He made a series of successful flights and established a line of eight supply depots on the route toward the South Pole. On November 28, 1929, after months of careful preparation, he started in the tri-motored monoplane "Floyd Bennett," named in honour of his pilot in the flight to the North Pole, and, with three companions, Bernt Balchen, pilot, Captain A. C. McKinley, map photographer, and Harold I. June, radio operator, headed the plane due south toward the pole, some 500 miles distant from his base. The most serious obstacle was a range of mountains, some of them 15,000 feet high, about half way to the pole. The plane was heavily loaded, and, to surmount the pass, it was necessary to throw overboard two bags of food. The plane slipped over the pass and the rest of the way to the pole across the snow-covered plateau averaging 10,000 ft. was comparatively easy. Byrd circled about the pole, headed northward, guided by the Burnstead sun compass, and returned, reaching his base in slightly under 19 hours. On December 21 Byrd received the rank of rear admiral in recognition of his successful flight. He returned in 1930.

**BYRD, WILLIAM** (1542 or 1543–1623), one of the greatest of English musical composers, was probably a member of one of the numerous Lincolnshire families of that name who were to be found at Lincoln, Spalding, Pinchbeck, Moulton and Epworth in the 16th century. According to Wood, he was "bred up to musick under Thomas Tallis." He was appointed organist of Lincoln cathedral on Feb. 27, 1563, and on Sept. 14, 1568, was married at

St. Margaret in the Close to Ellen or Julian Birley. On Feb. 22, 1570, he was sworn in as a member of the Chapel Royal, but he does not seem to have left Lincoln immediately. In the Chapel Royal he shared with Tallis the honorary post of organist, and on Jan. 22, 1575, the two composers obtained a licence for twenty-one years from Elizabeth to print and sell music and music-paper, a monopoly which does not seem to have been at all remunerative. In 1575 Byrd and Tallis published a collection of Latin motets for five and six voices, printed by Thomas Vautrollier.

In 1578 Byrd and his family were living at Harlington, Middlesex. As early as 1581 his name occurs among lists of recusants, and though he retained his post in the Chapel Royal he was throughout his life a Catholic. In 1579–80 he set a three-part song in Thomas Legge's Latin play *Ricardus Tertius*. In 1588 he published *Psalmes, Sonets and Songs of Sadnes and Pietie*, and in the same year contributed two madrigals to Nicolas Yonge's *Musica Transalpina*. In 1589 appeared *Songs of Sundrie Natures*, a second edition of which was issued in 1610. In the same year he published *Liber Primus Sacrarum Cantionum*, a second series of which was brought out in 1591. In 1590 two madrigals by Byrd were included in Thomas Watson's *First Sette of Italian Madrigalls Englished*; one of these seems to have been sung before Queen Elizabeth on her visit to Lord Hertford at Elvetham in 1591. In April 1592 Byrd was still living at Harlington, but about 1593 he became possessed of the remainder of a lease of Stondon Place, Essex, a farm of some 200 acres, belonging to William Shelley, who was shortly afterwards convicted of high treason. The property was sequestered, and on July 15, 1595, Byrd obtained a Crown lease of it for the lives of his eldest son Christopher and his daughters Elizabeth and Rachel.

In 1603 Easte published a work (no copies of which are known to exist) entitled *Medulla Musicke. Sucked out of the sappe of two [of] the most famous Musitians that ever were in this land, namely Master Wylliam Byrd . . . and Master Alphonso Ferasbosco . . . either of whom having made 40<sup>tie</sup> severall waies (without contention), showing most rare and intricate skill in 2 partes in one upon the playne song Miserere*. In 1607 appeared two books of *Gradualia*, a second edition of which was issued in 1610. In the following year he published *Psalmes, Songs and Sonnets; some solemne, others joyfull, framed to the life of the Words*. Probably in the same year was issued *Parthenia*, a collection of virginal music, in which Byrd was associated with Bull and Orlando Gibbons. The last work to which he contributed was Sir Thomas Leighton's *Teares or Lamentacions of a Sorrowfull Soule* (1614). His death took place on July 4, 1623. He is entered in the Chapel Royal *Cheque Book* as a "father of musicke." His will, dated Nov. 15, 1622, shows that he remained a Catholic until the end of his life.

Besides the works already mentioned Byrd was the composer of three masses, for three, four and five voices respectively, which seem to have been published with some privacy about 1588: There exists a second edition (also undated) of the four-part mass; all three have recently appeared in modern editions, and increase Byrd's claim to rank as the greatest English composer of his age. In addition to his published works, a large amount still remains in ms., comprising nearly every kind of composition. The Fitzwilliam *Virginal Book* contains a long series of interesting pieces for the virginal, and more still remains unpublished in Lady Neville's *Virginal Book* and other contemporary collections. Byrd's industry was enormous, and though his work is unequal and the licences he allowed himself cannot always be defended on strict grounds, his Latin church music and his instrumental compositions entitle him to the highest rank among his contemporaries. As a madrigalist he was inferior to Morley, Wilbye and Gibbons, though even in this branch of his art he often displays charm and individuality.

In general the estimation in which this great English master is held by scholars and students has steadily advanced, this increased appreciation of his importance finding notable expression in the many celebrations held all over the country in connection with the tercentenary of his death in 1923, when also memorial tablets were erected in Lincoln cathedral and the parish church of Stondon Massey.

(W. B. S.)

**BYRD, WILLIAM** (1674–1744), Virginia planter and first man of letters in North America, was born at Belvidere, near the James river in Virginia, on Mar. 28, 1674. After receiving his education for the law in England, he returned, in 1696, to Westover, which he made “the quintessence of Virginia Aristocracy,” and where he became one of the most brilliant figures in colonial Virginia. For 35 years he was a member of the King’s Council, and during the last year of his life its president. He was one of the commissioners who established the North Carolina-Virginia boundary, and in 1733 founded Richmond, Va. Interested in art and science, a wit and a lover of books, he acquired probably the largest colonial library. Occasionally he forsook his fields of that “bewitching vegetable, tobacco,” for the field of letters. His “Westover Manuscripts,” first published in 1841, include: *The History of the Dividing Line; A Journey to the Land of Eden; A Progress to the Mines*. He died at Westover on Aug. 26, 1744.

See *The Writings of Colonel William Byrd of Westover in Virginia* Esq., edit. by J. S. Bassett (New York, 1901).

**BYRNIE**, a coat of linked mail (Icelandic, *brynja*). The chain-mail body armour worn by early Scandinavians and others. Mid-English *brinie*—a coat of mail which hung from the neck to the knees, the skirt being slit to facilitate riding on horseback. The Normans called it the *hawberk*. The back and front were so much alike that mistakes in putting it on were common, the classic example being that of William the Conqueror before the battle of Hastings.

**BYROM, JOHN** (1692–1763), English poet, writer of hymns and inventor of a system of shorthand, was born at Kersal Cell, near Manchester, on Feb. 29, 1692, and died on Sept. 26, 1763, in London. He became a fellow of Trinity College, Cambridge, in 1714. His first poem, “Colin to Phoebe,” a pastoral, appeared in the *Spectator*, No. 603. The heroine is said to have been Dr. Bentley’s daughter, Joanna, the mother of Richard Cumberland, the dramatist. After leaving the University Byrom went abroad, ostensibly to study medicine, but possibly his errand was political, for he was an adherent of the Pretender. He was elected a member of the Royal Society in 1724. On his return to London he taught a new method of shorthand of his own invention. His diary gives interesting portraits and letters of the many great men of his time whom he knew intimately. A collection of his poems was published in 1773, and he is included in Alexander Chalmers’s *English Poets*. His system of shorthand was not published until after his death, when it was printed as *The Universal English Shorthand; or the way of writing English in the most easy, concise, regular and beautiful manner, applicable to any other language, but particularly adjusted to our own* (Manchester, 1767).

*The Private Journal and Literary Remains of John Byrom, related by Richard Parkinson, D.D.*, was published by the Chetham Society (1854–57).

**BYRON, GEORGE GORDON BYRON, 6TH BARON** (1788–1824), English poet, was born in London at 16 Holles street, Cavendish square, on Jan. 22, 1788. The Byrons were of Norman stock, but the founder of the family was Sir John Byron, who entered into possession of the priory and lands of Newstead in the county of Nottingham in 1540. From him it descended (but with a bar sinister) to a great-grandson, John (1st Baron) Byron (q.v.), a Cavalier general, who was raised to the peerage in 1643. The first Lord Byron died childless, and was succeeded by his brother Richard, the great-grandfather of William, the 5th lord, who outlived son and grandson, and was succeeded by his great-nephew, the poet. Admiral the Hon. John Byron (q.v.) was the poet’s grandfather. His eldest son, Captain John Byron, the poet’s father, was a libertine by choice and in an eminent degree. He caused to be divorced, and married (1779) as his first wife, the marchioness of Carmarthen (born Amelia D’Arcy), Baroness Conyers in her own right. One child of the marriage survived, the Hon. Augusta Byron (1783–1851), the poet’s half-sister, who, in 1807, married her first cousin, Col. George Leigh. John Byron’s second marriage to Catherine Gordon (b. 1765) of Gight in Aberdeenshire took place at Bath on May 13, 1785. He is said to have squandered the fortunes of both wives. It is certain that Gight

was sold to pay his debts (1786), and that the sole provision for his wife was a settlement of £3,000. It was an unhappy marriage. There was an attempt at living together in France, and, when this failed, Mrs. Byron returned to Scotland. On her way thither she gave birth to a son, christened George Gordon after his maternal grandfather, who was descended from Sir William Gordon of Gight, grandson of James I. of Scotland. After a while her husband rejoined her, but went back to France and died at Valenciennes on Aug. 2, 1791. His wife was not a bad woman, but she was not a good mother. Vain and capricious, passionate and self-indulgent, she mismanaged her son from his infancy, now provoking him by her foolish fondness, and now exciting his contempt by her paroxysms of impotent rage. In the conduct of her affairs she was praiseworthy. She hated and avoided debt, and when relief came (a civil list pension of £300 a year) she spent most of it upon her son. The violence of her temper was abnormal. Her father committed suicide, and it is possible that she inherited a tendency to mental derangement.

The poet’s first years were spent in lodgings at Aberdeen. His mother found him two tutors, first a clergyman named Ross, and then a good Latin scholar named Paterson, the son of the Byrons’ shoemaker. From 1794 to 1798 he attended the grammar school, “threading all classes” till he reached the fourth. He was lame from his birth. His right leg and foot, possibly both feet, were contracted by infantile paralysis, and, to strengthen his muscles, his mother sent him in the summers of 1796–97 to a farm house on Deeside. To his Scottish upbringing he owed his love of mountains, his love and knowledge of the Bible, and too much Calvinism for faith or unfaith in Christianity. The death of his great-uncle (May 19, 1798) placed him in possession of the title and estates. Early in the autumn Mrs. Byron travelled south with her son and his nurse, and for a time made her home at Newstead Abbey. Byron was old enough to know what had befallen him. “It was a change from a shabby Scotch flat to a palace,” a half-ruined palace, indeed, but his very own. It was a proud moment, but in a few weeks he was once more in lodgings. The shrunken leg did not improve, and acting on bad advice his mother entrusted him to the care of a quack named Lavender, truss-maker to the general hospital at Nottingham. His nurse who was in charge of him maltreated him, and the quack tortured him to no purpose. At his own request he read Virgil and Cicero with a tutor.

In August 1799, he was sent to a preparatory school at Dulwich. The master, Dr. Glennie, gave the boy the free run of his library. He read a set of the *British Poets* from beginning to end more than once. This, too, was an initiation and a preparation. He remained at Dulwich till April 1801, when, on his mother’s intervention, he was sent to Harrow, then under Dr. Drury. His school days, 1801–05, were fruitful in two respects. He learned enough Latin and Greek to make him a classic, if not a classical scholar, and he made friends with his equals and superiors. He learned something of his own worth and of the worth of others. “My school-friendships,” he says, “were with me passions.” Two of his closest friends died young, and from Lord Clare, whom he loved best of all, he was separated by chance and circumstance. He was an odd mixture, now lying dreaming on his favourite tombstone in the churchyard, now the ring-leader in whatever mischief was afoot. He was a “record” swimmer, and, in spite of his lameness, enough of a cricketer to play for his school at Lord’s, and yet he found time to read and master standard works of history and biography.

When he was a boy between eight and ten at Aberdeen he had “fallen in love” with his cousin, Mary Duff. Now, in the mid-summer of 1803, when he was in his sixteenth year, he fell in love, seriously, with his distant relative, Mary Anne Chaworth, a “minor heiress” of the hall and park of Annesley, which marches with Newstead. Two years his senior, she was already engaged to a neighbouring squire. Mary Chaworth is the subject of at least five of his early poems, including the pathetic stanzas, “Hills of Annesley,” and there are allusions to his love story in *Childe Harold* (c. 1 s.v.), and in “The Dream” 1816. The Easter holidays of 1804 were spent at Burgage Manor, Southwell, where Mrs. Byron had established herself, leaving Newstead Abbey to a tenant, Lord Grey of Ruthyn.

Byron went into residence at Trinity College, Cambridge, in Oct. 1805. Cambridge did him no good. "The place is the devil," he said, and according to his own showing he did homage to the *genius loci*. There he made friends who were worthy of his choice. Among them were the scholar-dandy Scrope, Charles Skinner Matthews, Berdmore Davies, Francis Hodgson, who died provost of Eton, and, best friend of all, John Cam Hobhouse (afterwards Lord Broughton). And there was another friend, a chorister named Edleston, a "humble youth" for whom he formed an attachment. He died whilst Byron was still abroad (May 1811), and the *Thyrza* poems of 1811-12 have been said, though on questionable evidence, to refer to his death. During the vacation of 1806, and in 1807 which was one "long vacation," he wrote most of his "Juvenile Poems," which were printed in a thin quarto of 66 pages by S. and J. Ridge of Newark. The "advertisement" is dated Dec. 23, 1806, but before that date he had begun to prepare a second collection for the press. One poem ("To Mary") contained at least one stanza which was frankly indecent, and yielding to advice he gave orders that the entire issue be thrown into the fire. Early in January 1807 an expurgated collection entitled *Poems on Various Occasions* was ready for private distribution. Encouraged by Henry Mackenzie and Lord Woodhouselee, he determined to recast this second issue and publish it under his own name. *Hours of Idleness*, "by George Gordon Lord Byron, a minor," was published in June 1807. The fourth and last issue of *Juvenilia*, entitled *Poems, Original and Translated*, was published in March 1808.

*Hours of Idleness* enjoyed a brief triumph. *The Critical* and other reviews were "very indulgent," but the *Edinburgh Review* for Jan. 1808 contained a scathing article, not, as Byron believed, by Jeffrey, but by Brougham. The sole result was that it supplied fresh material and a new title for some rhyming couplets on "British Bards" which he had begun to write. A satire on Jeffrey, the editor, and Lord Holland, the patron of the *Edinburgh Review*, was slipped into the middle of "British Bards," and the poem, rechristened *English Bards and Scotch Reviewers* was published March 1, 1809.

In April 1808, whilst he was still "a minor," Byron entered upon his inheritance, and established himself at Newstead in September on leaving Cambridge. The possession of this lordly and historic domain was an inspiration in itself. It was an ideal home for one who was to be hailed as the spirit or genius of romance.

On March 13, 1809, he took his seat in the House of Lords. He had determined, as soon as he was of age, to travel in the East, but first he invited Hobhouse and three others to a house-warming. Perhaps the story of the revels of the party, as told in *Childe Harold* (canto 1, stanzas 5-9), need not be taken too seriously. Byron was angry because Lord De La Warr did not wish him good-bye, and visited his displeasure on friends and "lemans" alike. May and June were devoted to the preparation of an enlarged edition of his satire. At length, accompanied by Hobhouse and a small staff of retainers, he set out on his travels. He sailed from Falmouth on July 2, and reached Lisbon on July 7, 1809. The first two cantos of *Childe Harold's Pilgrimage* contain a record of the principal events of his first year of absence.

*Childe Harold* and the Eastern tales which followed laid English contemporary readers under a great debt to Byron. They were a liberal education in the manners and customs of "the gorgeous East," in the scenery, the art, the history and politics of Italy and Greece. He widened the horizon of his contemporaries, bringing within their ken wonders and beauties hitherto unknown or unfamiliar, and in so doing he heightened and cultivated, he "touched with emotion," the unlettered and unimaginative many, that "reading public" which despised or eluded the refinements and subtleties of less popular writers.

Byron sailed from Gibraltar on Aug. 16, and spent a month at Malta making love to Mrs. Spencer Smith (the "Fair Florence" of c. 11. s. xxix-xxxiii.). He anchored off Prevesa on Sept. 28. The second canto records a journey on horseback through Albania, then almost a *terra incognita*, as far as Tepeleni, where he was entertained by Ali Pacha (Oct. 20), a yachting tour along the shores of the Ambracian gulf (Nov. 8-23), a journey by land from

Larnaki to Athens (Dec. 15-25), and excursions in Attica, Sunium and Marathon (Jan. 13-25, 1810). Of the tour in Asia Minor, a visit to Ephesus (March 15, 1810), an excursion in the Troad (April 13), and the famous swim across the Hellespont (May 3), the record is to be sought elsewhere. The stanzas on Constantinople (lxxvii.-lxxxii.), where Byron and Hobhouse stayed for two months, though written at the time and on the spot, were not included in the poem till 1814. They are, probably, part of a projected third canto. On July 14 Hobhouse set sail for England and Byron returned to Athens.

Of Byron's second year of residence in the East little is known beyond the bare facts that he was travelling in the Morea during August and September, that early in October he was at Patras, having just recovered from a severe attack of malarial fever, and that by Nov. 14 he had returned to Athens and taken up his quarters at the Franciscan convent. Of his movements during the next five months there is no record, but of his studies and pursuits there is substantial evidence. He learnt Romaic, he compiled the notes to the second canto of *Childe Harold*. He wrote (March 12) *Hints from Horace* (published 1831), an imitation or loose translation of the *Epistola ad Pisones* (Art of Poetry), and (March 17) *The Curse of Minerva* (published 1815), a skit on Lord Elgin's deportation of the metopes and frieze of the Parthenon. He left Athens in April, passed some weeks at Malta, and landed at Portsmouth (c. July 20). Arrived in London he consulted his literary adviser and cousin, R. C. Dallas, with regard to the publication of *Hints from Horace*. Of *Childe Harold* he said nothing, but after some hesitation produced the ms. from a "small trunk," and, presenting him with the copyright, commissioned Dallas to offer it to a publisher. It was finally accepted by Murray of Fleet street, who undertook to share the profits of an edition with Dallas.

Meanwhile Mrs. Byron died suddenly from a stroke of apoplexy. Byron set off at once for Newstead, but did not find his mother alive. He had had but little affection for her while she lived, but her death touched him to the quick. "I had but one friend," he exclaimed, "and she is gone." Another loss awaited him. Whilst his mother lay dead in his house, he heard that his friend Matthews had been drowned in the Cam. Edleston and Wingfield had died in May, but the news had reached him on landing. There were troubles on every side. On Oct. 11 he wrote the "Epistle to a Friend" ("Oh, banish care," etc.) and the lines "To Thyrza," which, with other elegies, were appended to the second edition of *Childe Harold* (April 17, 1812). This cry of desolation, this open profession of melancholy, first excited the interest of contemporaries.

Towards the close of the year he made friends with Moore. Some lines in *English Bards* (ii. 466-467), taunting Moore on fighting a duel with Jeffrey with "leadless pistol," had led to a challenge, and it was not till Byron returned to England that explanations ensued, and that the challenge was withdrawn. The friendship which sprang up between them still serves Byron in good stead. Moore's *Life of Byron* (1830) is no doubt a picture of the man at his best, but it is a genuine likeness. At the end of October Byron moved to London and settled at 8 St. James's street. On Feb. 27, 1812, he made his first speech in the House of Lords on a bill which made the wilful destruction of certain newly invented stocking-frames a capital offence, speaking in defence of the riotous "hands" who feared that their numbers would be diminished by improved machinery. It was a brilliant speech and won the praise of Burdett and Lord Holland. He made two other speeches during the same session. *Childe Harold* (4to) was published on Tuesday, March 10, 1812. "The effect," says Moore, "was . . . electric, his fame . . . seemed to spring, like the palace of a fairy king, in a night." A fifth edition (8vo) was issued on Dec. 5, 1812. Just turned 24, he "found himself famous," a great poet, a rising statesman. Society was now at his feet. But the excitement and absorption of one reigning passion after another destroyed his peace of mind. His first affair of any moment was with Lady Caroline Lamb the wife of William Lamb (Lord Melbourne). The culmination of this tragic episode—tragic for the enamoured woman—was an unbelievable scene at Lady Heathcote's ball in June 1813, which was the talk of all London.

To Lady Caroline succeeded Lady Oxford, who was double his own age, and Lady Frances Wedderburn Webster, the "Ginevra" of his sonnets, the "Medora" of *The Corsair*.

There was no slackening of his poetical energies. In Feb. 1813 he published *The Waltz* (anonymously), he wrote and published *The Giaour* (published June 5, 1813) and *The Bride of Abydos* (published Nov. 29, 1813), and he wrote *The Corsair* (published Feb. 1, 1814). The Turkish Tales were even more popular than *Childe Harold*. Murray sold 10,000 copies of *The Corsair* on the day of publication.

In the summer of 1813 a new and potent influence came into his life. Mrs. Leigh, whose home was at Newmarket, came up to London on a visit. After a long interval the brother and sister met, and whether there is or is not any foundation for the dark story obscurely hinted at in Byron's lifetime, and afterwards made public property by Mrs. Beecher Stowe (*Macmillan's Magazine*, 1869, pp. 377-396), there is no question as to the depth and sincerity of his love for his "one relative." Byron passed the seasons of 1813-14 in London. Socially he was on the crest of the wave. He was a welcome guest at the great Whig houses, at Lady Melbourne's, at Lady Jersey's, at Holland House. Sheridan and Moore, Rogers and Campbell were his intimates and companions. He was a member of the Alfred, of Watier's, of the Cocoa Tree, and half a dozen clubs besides. After the publication of *The Corsair* he had promised an interval of silence, but the abdication of Napoleon evoked an Ode in his dishonour (April 16). *Lara, a Tale*, an informal sequel to *The Corsair*, was published anonymously on Aug. 6, 1814.

Newstead had been put up for sale, but pending the completion of the contract was still in his possession. During his last visit but one, whilst his sister was his guest, he became engaged to Miss Anne Isabella (Annabella) Milbanke (b. May 17, 1792; d. May 16, 1860), the only daughter of Sir Ralph Milbanke, Bart., and the Hon. Judith (born Noel), daughter of Lord Wentworth. She was an heiress, and in succession to a peerage in her own right (becoming Baroness Wentworth in 1856). She was a pretty girl of "a perfect figure," highly educated, a mathematician, and, by courtesy, a poetess. She had rejected Byron's first offer, but, believing that her cruelty had broken his heart and that he was an altered man, she was now determined on marriage. On her side there was ambition touched with fancy—on his, a wish to be married and some hope perhaps of finding an escape from himself. The marriage took place at Seaham in Durham on Jan. 2, 1815. Bride and bridegroom spent three months in paying visits, and at the end of March settled at 13 Piccadilly terrace, London.

Byron was a member of the committee of management of Drury Lane theatre, and devoted much of his time to his professional duties. He wrote but little poetry. *Hebrew Melodies* (published April 1815), begun at Seaham in October 1814, were finished and given to the musical composer, Isaac Nathan, for publication. *The Siege of Corinth* and *Parisina* (published Feb. 7, 1816) were got ready for the press. On Dec. 10, Lady Byron gave birth to a daughter christened Augusta Ada. The tale of their strange honeymoon shows that there were difficulties from the beginning. It is certain that before and after the child was born his conduct was so harsh, so violent and so eccentric, that his wife believed, or tried to persuade herself, that he was mad. Money difficulties were acute; and both Annabella and Augusta suffered from Byron's conduct.

On Jan. 15, 1816, Byron ordered his wife to leave the Piccadilly house, the bailiffs were in it, and he wished to break up the establishment. Lady Byron went home, claimed her father's protection, and demanded a separation from her husband. In 1869 Mrs. Beecher Stowe affirmed that Lady Byron had expressly told her that Byron was guilty of incest with his half-sister, Mrs. Leigh; and in 1905 the second Lord Lovelace (Lord Byron's grandson) printed *Astarte*, which is now held by most judges to prove the truth of this charge. At the time, neither Lady Byron nor her advisers supported their demand by this or any other charge of misconduct. Lady Byron continued to correspond with Augusta, whom she certainly desired to shield, and Byron used Augusta as a means of communication with his wife. The

tangled story is too complicated to be related here, and the reader must be referred to the authorities cited at the end of this article. To the end Byron hoped for a reconciliation, and he never ceased to lament the separation from his daughter.

The separation of the Byrons was the talk of the town. There was a balance of opinion, but politics turned the scale. Byron had recently published some pro-Gallican stanzas, "On the 'Star of the Legion of Honour,'" in the *Examiner* (April 7). The Whigs defended Byron as best they could, but his own world, with one or two exceptions, ostracized him. The "excommunicating voice of society," as Moore put it, was loud and insistent. The articles of separation were signed on or about April 18, and on Sunday, April 25, Byron sailed from Dover for Ostend. The "Lines on Churchill's Grave" were written whilst he was waiting for a favourable wind. Byron's ostracism in London was in a sense his liberation. It made him great. "The howl of contumely," wrote Macaulay, "followed him across the sea, over the Alps; it gradually waxed fainter; it died away. . . . His poetry became more popular than it had ever been; and his complaints were read with tears by thousands and tens of thousands who had never seen his face." He was from that moment the typical figure of the romantic movement, the artist who found his subject in his own sorrows, in his own remorse. His cry, "My pang shall find a voice," was the cry of René and of Werther. He displayed to the world, as Arnold has said, "the pageant of a bleeding heart."

Byron's route lay through the Low Countries, and by the Rhine to Switzerland. On his way he halted at Brussels and visited the field of Waterloo. He reached Geneva on May 25, where he met by appointment at Dejean's Hôtel d'Angleterre, Shelley, Mary Godwin and Jane (or "Claire") Clairmont. The meeting was probably at the instance of Claire, who had recently become Byron's mistress. On June 10 Byron moved to the Villa Diodati on the southern shore of the lake. Shelley and his party had already settled at an adjoining villa, the Campagne Montalègre. The friends were constantly together. On June 23 Byron and Shelley started for a yachting tour round the lake. They visited the castle of Chillon on June 26, and, being detained by weather at the Hôtel de l'Ancre, Ouchy, Byron finished (June 27-29) the third canto of *Childe Harold* (published Nov. 18), and began the *Prisoner of Chillon* (published Dec. 5, 1816). These and other poems of July-September 1816, e.g. "The Dream" and the first two acts of *Manfred* (published June 16, 1817), betray the influence of Shelley. Byron passed the summer at the Villa Diodati, where he also wrote the *Monody on the Death of Sheridan*, published Sept. 9, 1816. The second half of September was spent and devoted to "an excursion in the mountains." His journal (Sept. 18-29), which was written for and sent to Mrs. Leigh, is a great prose poem, the source of the word pictures of Alpine scenery in *Manfred*. His old friend Hobhouse was with him and he enjoyed himself, but at the close he confesses that he could not lose his "own wretched identity" in the "majesty and the power and the glory" of nature. Remorse was scotched, not killed. On Oct. 6 Byron and Hobhouse started via Milan and Verona for Venice, which was reached early in November. For the next three years Byron lived in or near Venice—at first, 1816-17, in apartments in the Frezzzeria, and after Jan. 1818 in the central block of the Mocenigo palace. At Venice he pursued a life of deliberate profligacy. Of two of his amours we learn enough or too much from his letters to Murray and to Moore—the first with his land-lord's wife, Marianna Segati, the second with Margarita Coggi (the "Fornarina"), a Venetian of the lower class, who amused him with her savagery and her wit. Nevertheless he worked hard, and about the middle of April 1817 set out for Rome, where, with Hobhouse as companion and guide, he stayed three weeks. He returned to Venice on May 28, but shortly removed to a villa at Mira on the Brenta, some 7m. inland. A month later (June 26) when memory had selected and reduced to order the first impressions of his tour, he began to work them up into a fourth canto of *Childe Harold*. Among the books which Murray sent out to Venice was a copy of Hookham Frere's *Whistlecraft*. Byron took the hint and produced *Beppo, a Venetian Story* (published anonymously on Feb. 28, 1818). He attributes his choice of the mock heroic *ottava-rima*

to Frere's example, but he was certainly familiar with Casti's *Novelle*, and, according to Stendhal, with the poetry of Buratti. The success of *Beppo* and a growing sense that "the excellent manner of *Whistlercraft*" was the manner for him, led him to study Frere's masters and models, Berni and Pulci. An accident had led to a great discovery.

The fourth canto of *Childe Harold* was published on April 28, 1818. In September he began *Don Juan*. His own account of the inception of his last and greatest work is characteristic but misleading. He says (Sept. 9) that his new poem is to be in the style of *Beppo*, and is "meant to be a little quietly facetious about everything." A year later (Aug. 12, 1819), he says that he neither has nor had a plan—but that "he had or has materials." By materials he means books, such as Dalzell's *Shipwrecks and Disasters by Sea*, or de Castelnau's *Histoire de la nouvelle Russie*, etc., which might be regarded as poetry in the rough. The "building up of the drama," as Shelley puts it, was a slow and gradual process. Cantos I, II, were published (4to) on July 15, 1819; Cantos III, IV, V, finished in Nov. 1820, were not published till Aug. 8, 1821. Cantos VI–XVI, written between June 1822 and March 1823, were published at intervals between July 15, 1823 and March 26, 1824. Canto XVII was begun in May 1823, but was never finished. A fragment of 14 stanzas, found in his room at Missolonghi, was first published in 1903.

He did not put all his materials into *Don Juan*. *Mazeppa, a tale of the Russian Ukraine*, based on a passage in Voltaire's *Charles XII*, was finished by Sept. 30, 1818 and published with an Ode on Venice on June 28, 1819. In the spring of 1819 Byron met in Venice, and formed a connection with, an Italian lady of rank, Teresa (born Gamba), wife of the Cavaliere Guiccioli. She was young and beautiful, well-read and accomplished. Married at 16 to a man nearly four times her age, she fell in love with Byron at first sight, soon became and for nearly four years remained his mistress. A good and true wife to him in all but name, she won from Byron ample devotion and a prolonged constancy, though he found the position of accredited *cavaliere servente* irksome. Her volume of *Recollections (Lord Byron jugé par les témoins de sa vie, 1869)*, taken for what it is worth, is testimony in Byron's favour. The countess left Venice for Ravenna at the end of April; within a month she sent for Byron, and on June 10 he arrived at Ravenna and took rooms in the Strada di Porto Sisi. The house (now No. 295) is close to Dante's tomb, and to gratify the countess and pass the time he wrote the *Prophecy of Dante* (published April 21, 1821). According to the preface the poem was a metrical experiment, an exercise in *tersa rima*; but it had a deeper significance. It was "intended for the Italians." Its purport was revolutionary. In the fourth canto of *Childe Harold*, already translated into Italian, he had attacked the powers, and "Albion most of all" for her betrayal of Venice, and he appeals to the country of his adoption to strike a blow for freedom—to "unite." It is difficult to realize the force or extent of Byron's influence on continental opinion. His own countrymen admired his poetry, but abhorred and laughed at his politics. Abroad he was the prophet and champion of liberty. His hatred of tyranny, his defence of the oppressed, made him a power in Europe. It brought consolation and encouragement, and it was not spoken in vain. It must, however, be borne in mind that Byron was more of a king-hater than a people-lover. He was against the oppressors, but he disliked and despised the oppressed. He was aristocrat by conviction as well as birth, and if he espoused a popular cause it was *de haut en bas*. His connection with the Gambas brought him into touch with the revolutionary movement, and thenceforth he was under the espionage of the Austrian embassy at Rome. He was suspected and "shadowed," but he was left alone.

Early in September Byron returned to La Mira, bringing the countess with him. A month later he was surprised by a visit from Moore, who was on his way to Rome. Byron installed Moore in the Mocenigo palace and visited him daily. Before the final parting (Oct. 11) Byron placed in Moore's hands the ms. of his *Life and Adventures* brought down to the close of 1816. Moore, as Byron suggested, pledged the ms. to Murray for 2,000 guineas, to

be Moore's property if redeemed in Byron's lifetime, but if not, to be forfeit to Murray at Byron's death. On May 17, 1824, with Murray's assent and goodwill, the ms. was burned in the drawing-room of 50 Albemarle street. Neither Murray nor Moore lost their money. The Longmans lent Moore a sufficient sum to repay Murray, and were themselves repaid out of the receipts of Moore's *Life of Byron*. Byron told Moore that the memoranda were not "confessions," that they were "the truth but not the whole truth." They did not explain the cause or causes of the separation from his wife. An anonymous work entitled *The Life, Writings, etc., of . . . Lord Byron* (3 vols., 1825) purports to give "Recollections of the Late Destroyed Manuscript." To judge by internal evidence (see "The Wedding Day," etc., ii. 278–284) there is some measure of truth in this assertion, but the work as a whole is untrustworthy.

At the close of 1819 Byron finally left Venice and settled at Ravenna in his own apartments in the Palazzo Guiccioli. At Ravenna his literary activity was greater than ever. His translation of the first canto of Pulci's *Morgante Maggiore* (published in *The Liberal*, No. IV., July 30, 1822), a laborious and scholarly achievement, was the work of the first two months of the year. From April to July he was at work on the composition of *Marino Faliero, Doge of Venice*, a tragedy in five acts (published April 21, 1821). Moved by the example of Alfieri he strove to reform the British drama by "a severer approach to the rules." He would read his countrymen a "moral lesson" on the dramatic propriety of observing the three unities. Eighteen additional sheets of the *Memoirs* and a fifth canto of *Don Juan* were written in the autumn, and in Jan. 1821 Byron began to work on his second "historical drama," *Sardanapalus*. But politics intervened, and little progress was made. He had been elected *capo* of the "Americani," a branch of the Carbonari, and his time was taken up with buying and storing arms and ammunition, and consultations with leading conspirators. Meanwhile a controversy had arisen between Bowles and Campbell with regard to the merits of Pope. Byron rushed into the fray. To avenge and exalt Pope, to decry the "Lakers," and to lay down his own canons of art, Byron addressed two letters to \* \* \* \* \* (i.e., John Murray), entitled "Strictures on the Life and Writings of Pope." The first was published in 1821, the second in 1835. Byron, the protagonist of the romantic movement, was, paradoxically, the persistent admirer of Pope and the classical English school, and the violent assailant of the Lake poets.

The revolution in Italy came to nothing, and by May 28, Byron had finished his work on *Sardanapalus*. The *Two Foscari*, a third historical drama, was begun on June 12 and finished on July 9. On the same day he began *Cain, a Mystery*. *Cain* startled and shocked the orthodox. It was not irreverent or blasphemous, but it treated accepted dogmas as open questions. *Cain* was published in the same volume with the *Two Foscari* and *Sardanapalus*, Dec. 19, 1821. The *Blues*, a skit upon literary coteries and their patronesses, was written in August. It was first published in *The Liberal*, No. III., April 26, 1823. When *Cain* was finished Byron turned from grave to gay, from serious to humorous theology. Southey had thought fit to eulogize George III. in hexameter verse. He called his funeral ode a "Vision of Judgment." In the preface there was an obvious reference to Byron. The "Satanic School" of poetry was attributed to "men of diseased hearts and depraved imaginations." Byron's revenge was complete. In his "Vision of Judgment" (published in *The Liberal*, No. I., Oct. 15, 1822) the tables are turned. The laureate is brought before the hosts of heaven and rejected by devils and angels alike. In October Byron wrote *Heaven and Earth, a Mystery (The Liberal, No. II., Jan. 1, 1823)*, a lyrical drama based on the legend of the "Watchers," or fallen angels of the Book of Enoch.

The countess and her family had been expelled from Ravenna in July, but Byron still lingered on in his apartments in the Palazzo Guiccioli. At length (Oct. 28) he set out for Pisa. On the road he met his old friend, Lord Clare, and spent a few minutes in his company. Rogers, whom he met at Bologna, was his fellow-traveller as far as Florence. At Pisa he rejoined the countess, who had taken on his behalf the Villa Lanfranchi on the Arno. At

Ravenna Byron had lived amongst Italians. At Pisa he was surrounded by a knot of his own countrymen, friends and acquaintances of the Shelleys. Among them were E. J. Trelawny, Thomas Medwin, author of the *Conversations of Lord Byron* (1824), and Edward Elliker Williams. His first work at Pisa was to dramatize Miss Lee's *Kruitzner, or the German's Tale*. He had written a first act in 1815, but as the ms. was mislaid he made a fresh adaptation of the story which he rechristened *Werner, or the Inheritance* (1822). Alone of Byron's plays *Werner* took hold of the stage. Macready's "Werner" was one of his most famous impersonations.

In the early spring Allegra, his daughter by Claire Clairmont, died at the convent of Bagna Cavallo on April 20, 1822. He had insisted on having the guardianship of the child, and had himself placed her in the convent. Soon after the death of Allegra, Byron wrote the last of his eight plays, *The Deformed Transformed* (published by John Hunt, Feb. 20, 1824). With the idea of having a paper of his own in which he could answer his critics and put forward his own theories he invited Leigh Hunt to Pisa, and undertook to lodge him with his wife and six children in the Villa Lanfranchi. The outcome of this arrangement was *The Liberal—Verse and Prose from the South*. Four numbers were issued between Oct. 1822 and June 1823. *The Liberal* did not succeed financially, and the joint ménage was a lamentable failure. *Correspondence of Byron and some of his Contemporaries* (1828) was Hunt's revenge for the slights—sometimes fancied slights—which he suffered in Byron's service. Yet Byron made generous allowances to the Hunts, and made over to John Hunt copyrights of enormous value. Yachting was one of the chief amusements of the English colony at Pisa. A schooner, the "Bolivar," was built for Byron, and a smaller boat, the "Don Juan" re-named "Ariel," for Shelley. Hunt arrived at Pisa on July 1. On July 8 Shelley, who had remained in Pisa on Hunt's account, started for a sail with his friend Williams and a lad named Vivian. The "Ariel" was wrecked in the Gulf of Spezia, and Shelley and his companions were drowned. On Aug. 16 Byron and Hunt witnessed the "burning of Shelley" on the seashore near Via Reggio. Byron told Moore that "all of Shelley was consumed but the heart." Whilst the fire was burning Byron swam out to the "Bolivar" and back to the shore. The violent emotion caused by the death of Shelley and the improvident swim brought on one of the many fevers which weakened his constitution and shortened his life.

The Austrian Government would not allow the Gambas or the countess Guiccioli to remain in Pisa. As a half measure Byron took a villa for them at Montenero near Leghorn, but as the authorities were still dissatisfied they removed to Genoa. At Genoa Byron took up his quarters with the Gambas at the Casa Saluzzo, and Hunt and his party at the Casa Negroto with Mrs. Shelley. Life at Genoa was uneventful. Of Hunt and Mrs. Shelley he saw as little as possible. Though his still unpublished poems were at the service of *The Liberal*, each number was badly received. Byron had broken with Murray and was offering *Don Juan* (cantos vi.-xii.) to John Hunt, the publisher of *The Liberal*, but he meditated a "run down to Naples" and a recommencement of *Childe Harold*. Home politics and the congress of Verona (Nov.-Dec. 1822) suggested a satire entitled *The Age of Bronze* (published April 1, 1823). By the middle of February (1823) he had completed *The Island; or Christian and his Comrades* (published June 26, 1823), based on Bligh's *Narrative of the Mutiny of the Bounty*, and Mariner's *Account of the Tonga Islands*. When *The Island* was finished, Byron went on with *Don Juan*, his last, and his greatest, work. In *Don Juan* he set himself to depict life as a whole. The style is often misnamed the mock-heroic. It might be more accurately described as humorous-realistic. His "plan was to have no plan" in the sense of synopsis or argument, but in the person of his hero to "unpack his heart," to avenge himself on his enemies, personal or political, to suggest an apology for himself and to disclose a criticism and philosophy of life. As a satirist in the widest sense of the word, as an analyser of human nature, he ranks among the greatest. It is a test of the quality of *Don Juan* that its reputation has slowly increased and that, in spite of occasional grossness and voluptuousness, it has come to be recognized

as Byron's masterpiece. *Don Juan* will be read for its own sake, for its beauty, its humour, its faithfulness. It is a "hymn to the earth," but it is a human sequence to "its own music chaunted."

Early in March the news reached him that he had been elected a member of the Greek Committee, a small body of influential Liberals who had taken up the cause of the liberation of Greece. Byron at once offered money and advice, and after some hesitation on the score of health, determined "to go to Greece." His first step was to sell the "Bolivar" to Lord Blessington, and purchase the "Hercules," a collier-built tub of 120 tons. On July 23 the "Hercules" sailed from Leghorn, and anchored off Cephalonia on Aug. 3. The party on board consisted of Byron, Pietro Gamba, Trelawny, Hamilton Browne, and six or seven servants. The next four months were spent at Cephalonia, at first on board the "Hercules," in the harbour of Argostoli, and afterwards at Metaxata. Byron took time to ascertain the real state of affairs in Greece. The revolutionary Greeks were split up into parties, not to say factions, and there were several leaders. At length he received a message from Prince Alexander Mavrocordato, urging him to come at once to Missolonghi, and enclosing a request from the legislative body "to co-operate with Mavrocordato in the organization of western Greece." Byron sailed from Argostoli on Dec. 29, 1823, and after an adventurous voyage landed at Missolonghi on Jan. 5, 1824. He met with a royal reception. Byron may have sought, but he did not find, "a soldier's grave." During his three months' residence at Missolonghi he advanced large sums of money for the payment of troops, for repair and construction of fortifications, for the provision of medical appliances. He brought opposing parties into line, and served as a link between Odysseus, the democratic leader of the insurgents, and Mavrocordato. He was eager to take the field, but a revolt in the Morea, and the repeated disaffection of his Suliot guard prevented him from undertaking the capture of Epacto, an exploit which he had reserved for his own leadership. On March 18 he received an invitation from Odysseus and other chiefs to attend a conference at Salona, and by the same messenger an offer from the government to appoint him "governor-general of the enfranchised parts of Greece." He promised to attend the conference but did not pledge himself to the immediate acceptance of office. But "roads and rivers were impassable," and the conference was inevitably postponed.

His health had given way, but he does not seem to have realized that his life was in danger. On Feb. 15 he was struck down by a fit, which left him speechless though not motionless. He recovered sufficiently to conduct his business as usual, and to drill the troops. But he suffered from dizziness in the head and spasms in the chest, and a few days later he was seized with a second though slighter convulsion. These attacks may have hastened but they did not cause his death. On April 9 a letter from his sister raised his spirits and tempted him to ride out with Gamba. It came on to rain, and though he was drenched to the skin he insisted on dismounting and returning in an open boat to the quay in front of his house. Two hours later he was seized with ague and violent rheumatic pains. On the 11th he rode out once more through the olive groves, attended by his escort of Suliot guards, but for the last time. Whether he had got his deathblow, or whether copious blood-letting by his incompetent attendant Bruno, made recovery impossible, he gradually grew worse, and on the ninth day of his illness fell into a comatose sleep. It was reported that in his delirium he had called out, half in English, half in Italian, "Forward—forward—courage! follow my example—don't be afraid!" and that he tried to send a last message to his sister and to his wife. He died at six o'clock in the evening of Easter Monday, April 19, 1824, aged 36 years and three months. Mavrocordato gave orders that 37 minute-guns should be fired at daylight and decreed a general mourning of 21 days. His body was embalmed and lay in state. On May 25 his remains, all but the heart, which is buried at Missolonghi, were sent back to England, and were finally laid beneath the chancel of the village church of Hucknall-Torkard on July 16, 1824. The authorities would not sanction burial in Westminster Abbey, and there is neither bust nor statue of Lord Byron in Poets' Corner.

The title passed to his first cousin as 7th baron, from whom the subsequent barons were descended. The poet's daughter Ada (d. 1852) predeceased her mother, but the barony of Wentworth went to her heirs. She was the first wife of Baron King, who in 1838 was created 1st earl of Lovelace, and had two sons (of whom the younger, b. 1839, d. 1906, was 2nd earl of Lovelace) and a daughter, Lady Anne, who married Wilfrid S. Blunt (q.v.). On the death of the 2nd earl the barony of Wentworth went to his daughter and only child, and the earldom of Lovelace to his half-brother by the 1st earl's second wife.

Throughout his stormy life Byron was faithful to his vocation as a poet. Poetry was often but not always an exaltation and a relief. He could fulfil his tasks in "hours of gloom." If he had not been a great poet, he would have gained credit as a painstaking and laborious man of letters. His habitual temperance was the outcome of a stern resolve. He had no scruples, but he kept his body in subjection as a means to an end. In his youth Byron was a cautious spendthrift. Even when he was "cursedly dipped" he knew what he was about; and afterwards, when his income was sufficient for his requirements, he kept a hold on his purse. He loved display, and as he admitted, spent money on women, but he checked his accounts and made both ends meet. On the other hand, the "gift of continency" he did not possess, nor trouble himself to acquire. He was, to use his own phrase, "passionate of body," and his desires were stronger than his will. Byron was kindly and generous by nature. He took pleasure in helping necessitous authors, men and women, not at all *en grand seigneur*, or without counting the cost, but because he knew what poverty meant, and a fellow-feeling made him kind. Even in Venice he set aside a fixed sum for charitable purposes. It is to his credit that neither libertinism nor disgrace nor remorse withered at its root this herb of grace. Cynical speeches with regard to friends and friendship, often quoted to his disadvantage, need not be taken too literally. Byron talked in accordance with the whim of the moment. His acts do not correspond with his words. He rejected both Protestant and Catholic orthodoxy, but like the Athenians he was "exceedingly religious." He could not, he did not wish to, detach himself from a belief in an Invisible Power. "A fearful looking form of judgment" haunted him to the last. Whatever his faults may have been, Byron had certain noble qualities which did not fail him at his worst. He was courageous, he was often kind, and he loved truth rather than lies. He was a worker and a fighter. He hated tyranny, and was prepared to sacrifice money and ease and life in the cause of popular freedom.

In his own lifetime Byron stood higher on the continent of Europe than in England or even in America. His works as they came out were translated into French, German, Italian and Russian, and the stream of translation has never ceased to flow. The *Bride of Abydos* has been translated into ten, *Cain* into nine languages. Of *Manfred* there is one Bohemian translation, two Danish, two Dutch, two French, nine German, three Hungarian, three Italian, two Polish, one Romaic, one Rumanian, four Russian and three Spanish translations. The dictum or verdict of Goethe that "the English may think of Byron as they please, but this is certain that they show no poet who is to be compared with him" was and is the keynote of continental European criticism. A survey of European literature is a testimony to the universality of his influence. Victor Hugo, Lamartine, Delavigne, Alfred de Musset, in France; Börne, Müller and Heine in Germany; the Italian poets Leopardi and Giusti; Pushkin and Lermontov among the Russians; Mickiewicz and Slowacki among the Poles—more or less as eulogists or imitators or disciples—were of the following of Byron. The part he played in revolutionary politics endeared him to those who were struggling to be free. He had the passion and the energy, the brilliance—in a word the genius—which made his voice heard throughout Europe. He was the least insular, the most European, of British poets. It was as the creator of new types, "forms more real than living man," that Byron appealed to the artistic sense and to the imagination of Latin, Teuton or Slav. That "he taught us little" of the things of the spirit, that he knew no cure for the sickness of the soul, were considerations which lay outside the province of literary criticism. "It is a mark," says

Goethe (*Aus meinem Leben: Dichtung und Wahrheit*, 1876, iii. 125), "of true poetry, that as a secular gospel it knows how to free us from the earthly burdens which press upon us, by inward serenity, by outward charm." Now of this "secular gospel" the redemption from "real woes" by the exhibition of imaginary glory and imaginary delights, Byron was both prophet and evangelist.

Byron was 5ft. 8in. in height, and strongly built; only with difficulty and varying success did he prevent himself from growing fat. At 35 he was extremely thin. He was "very slightly lame," but he was painfully conscious of his deformity and walked as little and as seldom as he could. He had a small head covered and fringed with dark brown or auburn curls. His forehead was high and narrow, of a marble whiteness. His eyes were of a light grey colour, clear and luminous. His nose was straight and well-shaped, but "from being a little too thick, it looked better in profile than in front face." Moore says that it was in "the mouth and chin that the great beauty as well as expression of his fine countenance lay." The upper lip was of a Grecian shortness and the corners descending. His complexion was pale and colourless. Scott speaks of "his beautiful pale face—like a spirit's, good or evil." Charles Matthews said that "he was the only man to whom he could apply the word beautiful." Coleridge said that "if you had seen him you could scarce disbelieve him . . . his eyes the open portals of the sun—things of light and for light." He was likened to "the god of the Vatican," the Apollo Belvedere.

The best-known portraits are: (1) Byron at the age of seven by Kay of Edinburgh; (2) a drawing of Lord Byron at Cambridge by Gilchrist (1808); (3) a portrait in oils by George Sanders (1809); (4) a miniature by Sanders (1812); (5) a portrait in oils by Richard Westall, R.A. (1813); (6) a portrait in oils (Byron in Albanian dress) by Thomas Phillips, R.A. (1813); (7) a portrait in oils by Phillips (1813); (8-9) a sketch for a miniature, and a miniature by James Holmes (1815); (10) a sketch by George Henry Harlow (1818); (11) a portrait in oils by Vincenzo Camuccini (in the Vatican) c. 1822; (12) a portrait in oils by W. H. West (1822); (13) a sketch by Count D'Orsay (1823). Busts were taken by Bertel Thorwaldsen (1817) and by Lorenzo Bartolini (1822). The statue (1829) in the library of Trinity College, Cambridge, is by Thorwaldsen after the bust sculptured in 1817.

**BIBLIOGRAPHY.**—Editions: The important editions of Byron's works are: *The Works of Lord Byron with his Letters and Journals and his Life*, by Thomas Moore, 17 vols. (1832-33); *The Works of Lord Byron*, new enlarged and revised edition, the *Letters and Journals*, ed. R. E. Prothero (Lord Ernle), 6 vols.; the *Poetry*, ed. E. H. Coleridge, 7 vols. (1898-1903); *The Poetical Works of Lord Byron*, with memoir by E. H. Coleridge (1905); *Lord Byron's Correspondence chiefly with Lady Melbourne* (1922). Of the many editions of the Poems, one of the best is: *Poems of Lord Byron* selected and arranged in chronological order with preface, by H. J. C. Grierson (1923).

Biographies, notices, etc.: J. C. Hobhouse, *Journey through Albania . . . with Lord Byron* (1812, rep. 2 vols., 1813 and 1855); H. de Stendhal, *Lord Byron en Italie* (1816); Dr. John Watkins, *Memoirs of the Life and Writings . . . of Lord Byron* (1822); E. Brydges, *Letters on the Character and Poetical Genius of Lord Byron* (1824); *Correspondence of Lord Byron with a Friend*, 3 vols. (Paris, 1824); R. C. **BYRON, HENRY JAMES** (1834-1884), English playwright, was born in Manchester in Jan. 1834. He entered the Middle Temple as a student in 1858, but soon joined a provincial company as an actor. He was the first editor of the weekly comic paper *Fun*, and started the short-lived *Comic Trials*. His first successes were in burlesque; but in 1865 he joined Miss Marie Wilton (afterwards Lady Bancroft) in the management of the Prince of Wales's theatre, near Tottenham Court road. Here several of his pieces, comedies and extravaganzas were produced with success; but, upon starting management on his own account in the provinces, he was financially unfortunate. The commercial success of his life was secured with *Our Boys*, which was played at the Vaudeville from Jan. 1875 till April 1879—a then unprecedented "run." *The Upper Crust*, another of his successes, gave a congenial opportunity to Mr. J. L. Toole for one of his inimitably broad character-sketches. H. J. Byron was the author of some of the most popular stage pieces of his day. He wrote one novel, *Paid in Full* (1865). He had many friends, among whom he was justly popular for geniality and imperturbable good temper. He died at Clapham on April 11, 1884.

**BYRON, JOHN BYRON**, 1st BARON (c. 1600-1652), English cavalier, was the eldest son of Sir John Byron (d. 1625), a member of an old Lancashire family which had settled at Newstead, near Nottingham. During the third decade of the 17th century Byron was member of parliament for the town and afterwards for the county of Nottingham. In Dec. 1641, the king made him lieutenant of the Tower of London, but in consequence of the persistent demand of the House of Commons he resigned in 1642. Byron fought at the skirmish at Powick Bridge; he commanded his own regiment of horse at Edgehill and at Roundway Down; and at the first battle of Newbury Falkland placed himself under his orders. His defeat at Nantwich, in Jan. 1644, compelled him to retire into Chester, and he was made governor of this city by Prince Rupert. At Marston Moor, as previously at Edgehill, Byron's rashness gave a great advantage to the enemy; then, after fighting in Lancashire and north Wales, he returned to Chester, which he held for about twenty weeks in spite of the king's defeat at Naseby and the general hopelessness of the royal cause. Having obtained favourable terms he surrendered the city in Feb. 1646. Byron took some slight part in the second Civil War, and was one of the seven persons excepted by parliament from all pardon in 1648. But he had already left England, and he lived abroad in attendance on the royal family until his death in Paris on Aug. 23, 1652. Although twice married Byron left no children, and his title descended to his brother Richard (1605-79), who had been governor of Newark. Byron's five other brothers served Charles I. during the Civil War, and one authority says that the seven Byrons were all present at Edgehill.

**BYRON, HON. JOHN** (1723-1786), British vice-admiral, second son of the 4th Lord Byron, and grandfather of the poet, was born on Nov. 8, 1723. While still very young, he accompanied Anson in his voyage of discovery round the world. He saw a great deal of hard service and stormy weather, and was nicknamed by the sailors, "Foul-weather Jack." It is to this that Lord Byron alludes in his *Epistle to Augusta*:—

A strange doom is thy father's son's, and past  
Recalling as it lies beyond redress,  
Reversed for him our grandsire's fate of yore,  
He had no rest at sea, nor I on shore.

In 1768 he published a *Narrative* of some of his early adventures with Anson, which was to some extent utilized by his grandson in *Don Juan*. In 1769 he was appointed governor of Newfoundland. In 1775 he attained his flag rank, and in 1778 became vice-admiral. In the same year he was despatched with a fleet to watch the movements of the Count d'Estaing, and in July, 1779 fought an indecisive engagement with him off Grenada. He died on April 10, 1786.

**BYSTROM, JOHAN NIKLAS** (1783-1848), Swedish sculptor, was born on Dec. 18, 1783, at Philipstad, and died at Rome on March 13, 1848. The greater part of his life was spent in Italy. His colossal statues of the Swedish kings, in Stockholm, form his most celebrated work.

**BYTOWNITE** (named from Bytown, now Ottawa, in Canada), a rock-forming mineral of the plagioclase (*q.v.*) group of feldspars. The name is now restricted to feldspars intermediate in composition between labradorite (*q.v.*) and anorthite (*q.v.*), and arbitrarily reserved for solid solutions of composition-range  $Ab_{30}An_{70}$  to  $Ab_{10}An_{90}$ .

**BYWATER, INGRAM** (1840-1914), English classical scholar, was born in London June 27 1840, and died there Dec. 17 1914. He was university reader in Greek at Oxford, 1883, and regius professor 1893-1908, and was an authority on Aristotle.

Chief works: *Heracliti Ephesii Reliquiae* (1877); *Prisciani Lydi quae extant* (edited for the Berlin Academy in the *Supplementum Aristotelicum*, 1886); Aristotle, *Ethica Nicomachea* (1890), *De Arte Poetica* (1898); *Contributions to the Textual Criticism of the Nicomachean Ethics* (1892).

**BYZANTINE AND ROMANESQUE ARCHITECTURE.** Byzantine architecture is that which was developed under the Eastern Roman empire from the time of Constantine (323-337) down to its fall in 1453. Offshoots of this style in Russia (see RUSSIAN ARCHITECTURE) and the Balkans, and along the east coast of Italy are frequently included. Romanesque architecture is the style which grew up in western and central Europe after the fall of Rome, 476, and prior to the development of Gothic. (See GOTHIC ARCHITECTURE.) The Romanesque type, found in Rome itself, is usually termed Early Christian or Basilican. (See BASILICA.)

#### BYZANTINE ARCHITECTURE

**Origin and Development.**—In the 100 years preceding Constantine, Eastern influence on Roman culture increased continually. In architecture, the Syrian provinces developed a vivid style of their own, which by the time of Hadrian (117-138) already showed marked changes from classic practice. These resulted from three things: an abundance of hard stone, a lack of timber and Eastern love of surface ornament. The differences in building materials produced great originality in stone vaulting, and the love of surface ornament reduced the projections in Roman carving. (See de Vogüé, *Syrie Centrale*, and Butler, *Architecture and Other Arts*.)

Many builders working in the later Roman empire seem to have had Syrian training, and the palace of Diocletian at Spalato (c. 300) shows how profoundly this influence affected Roman ornament. When Constantine moved his capital to Constantinople (330) the importance of the Syrian influence in its architecture was inevitable. The germ of the style first appeared in utilitarian works. In Constantine's great cistern, known as the Binbirderek (the reservoir of a thousand and one columns), a truncated, pyramidal block, known as an impost block or dossier and used as a column capital appears. Moreover, the vault consists of square, groined bays with the crowns so raised at the centre that they approach the pendentive dome in shape. Throughout their history the Romans sought unsuccessfully a method of placing a dome over a square or polygonal room by means of squinches (*q.v.*), diagonal arches, etc. It remained for Byzantine architects to solve the problem and realize the structural and artistic possibilities of the true pendentive, which is merely the section of a

spherical dome. The church of S. Sophia, Salonika (*c.* 450) is probably the earliest building in which the pendentive is used in connection with a dome at the crossing of a church.

Ornament of this period also shows many changes from Roman precedent. These comprise the extended use of the impost block, the flattening of carving, the elimination of entablature mouldings, and the development of coloured surface decoration by means of marble panels and glass mosaic. Where entablatures occur, the members of architrave and cornice blend together in continuous bands of carved richness. These transitional details appear in the 5th century churches of S. John the Baptist, Constantinople, and S. Demetrius, Salonika. In the church of SS. Sergius and Bacchus in Constantinople (*c.* 523), ornament of this new type is first found decorating a domical building of large size. Here, however, the dome springs directly from an octagon, without pendentives; this church, however, shows a definite attempt to combine a large dome with a polygonal plan of Syrian type and to decorate the whole with columned galleries in which there are many variations from classical prototypes.

With the beginning of the church of S. Sophia at Constantinople in 532, the Byzantine style came to its maturity; a perfect blend of Roman planning and Eastern structure and ornament. The architects, Isidorus of Miletus and Anthemius of Tralles, both from the East, conceived the daring idea of substituting for the groined vault of the Roman basilica of Constantine an enormous dome on pendentives and a half dome at each end. From the semi-circular walls supporting the half domes, small apses are opened out and pierced by arcades carried on columns, so that the sense of openness is tremendous and the great weights involved are concentrated on a few colossal piers. The side aisles are separated from the nave, by arcades, pierced by means of wide arched passages, the great piers supporting and buttressing the dome. The aisles are in two storeys, the second, as always in Byzantine churches, used for a woman's gallery. In front of this building was a long, narrow narthex (*q.v.*), groin vaulted and opening by many doors into the nave and aisles. The church is a historical one because here, at last, Byzantine structural and decorative genius achieved complete definitive expression. In it complete freedom from Roman precedent is won and the ornament, even when the effect is produced by carving, is frankly a surface ornament. The richness of this carving is the richness of lace. It combines admirably with the veined marble panels which

sheath the walls and the piers, the intricate decoration of the arcade spandrels, and the glass mosaics, mainly on a gold ground, of the vaults, to produce an interior of a character and power hitherto unknown. The success of such a building had a profound effect, not only in Constantinople but even in Ravenna, in the distant Italian exarchate where the church of S. Vitale (547) is entirely in the Byzantine style. It was Byzantine influence which dominated the early architecture of Venice 500 years later. Byzantine architecture soon separated into local schools, Constantinople, Greece, the Balkans, Armenia, Italy and Russia.

**Constantinople.**—In its later phases this school is characterized by the use of the drum, which is a vertical cylindrical wall, pierced with windows, between the top of the pendentives and the base of the dome proper, which it carries. This appears first in the dome of S. Irene (probably *c.* 712). The greater number of churches still existing in Constantinople are of comparatively small size, and the dome drum is frequently of disproportionate height. As time went on, more and more attention was given to exterior design, especially by the use of alternating courses of brick and stone, arched recesses and decorative cornices, often in brick. Frequently, too, the walls of the drum were carried up above the spring of the dome, which was covered by a conical roof, as, for instance, in the church of S. Theodore Tyrone, in Constantinople. Decorative wall panelling of geometric marble mosaic, as in the palace hall of the Tekfur Serai at Constantinople, also became more common. Internally, the decorative scheme of the later churches is merely a development of that of S. Sophia, Constantinople, with gradually increasing complexity in the mosaics, of which beautiful examples remain in the 12th century church now known as Kahriyeh Djami, Constantinople.

**Greece.**—In all Greek churches there seems to be a love of small scale for its own sake, quite different from the Constantinople tradition. Proportions are always high and narrow and drums carrying miniature domes are of extravagant height (*e.g.*, the Holy Apostles, Salonika, 12th century). There is, also, a love of marble for exterior panelling, used much as the Constantinople architects employed it for interior work. In the small cathedral at Athens, an interesting effect is gained by building into the exterior walls heterogeneous, decorative panels of carved marble.

**The Balkans.**—Yugoslavia and Albania contain many churches of Byzantine type, dating from a late period (*c.* 1500–1800). In almost all of these the high, stilted character is still further

increased by the breaking up of the façade into many long, slim, arched recesses frequently emphasized by painting the arches white against the yellow wall. Occasionally, further exterior richness is given by complicated carving of Armenian character. The lavishness of the outside of these Balkan churches increased continually, until, in the 17th and 18th centuries, there began to appear signs of influences from western Europe; the resulting adulterated mixture had a certain naive extravagance, but was without vitality and soon died.

**Armenia.**—Here a vivid and characteristic Byzantine style existed between the 4th and the 11th centuries. Armenian architecture is peculiarly interesting historically because its monuments are built out of cut stone, instead of the brick common in Constantinople, and is closely related to Syrian examples. Although often later in date, the monuments show forms transitional between early Christian art of Syria (such as the basilica of Kalaat Simaan) and the matured Byzantine of Constantinople. Armenian churches are built of carefully cut ashlar, or smooth stone masonry; the entire outside faces are decorated with rich patterns of incised lines and softly modulated mouldings, which frequently take the form of decorative arches with no relation to the structure. The cross and the interlace were common. The eastern apse or apses were frequently in the thickness of the wall. The most characteristic examples of the Armenian style are the many churches of the ruined city of Ani.

**Italy.**—In addition to the early work in Ravenna (e.g., S. Vitale, noted for its mosaics) a Byzantine school of quite different character developed in Venetia, from the 10th century on. The Venetians, whose wealth was based on commerce with the East, turned naturally to Constantinople for artistic inspiration, but they put the stamp of their own character on their Byzantine work. This is especially true of their domestic architecture, for the typical Venetian palace, marble sheathed, with arched windows and pierced balconies, took form during the Byzantine period. St. Mark's, the great monument of Venice, is the second most important Byzantine monument in the world. Here the structural idea, five domes covering a plan of Greek cross type, was borrowed from the Church of the Holy Apostles in Constantinople, and built in a thoroughly Byzantine manner, and the decorative marble sheathing and glass mosaics were similar. In detail the Roman influence is stronger than that of Constantinople; capitals often closely resemble the Roman Corinthian; the acanthus leaf is treated with its full, classic, curving relief. In capitals and bands, a touch of fresh naturalism is found; birds, animals and human figures are used with a verve quite different from the conventionalized lace of Constantinople. The columns of the screens which separate nave and aisles carry a full classic entablature. The front of St. Mark's, as it exists at the present time, represents many alterations and rebuildings during the Gothic period. Only the essential structural framework and the tiers of marble columns are of the original Byzantine design. The onion outer domes, with their elaborate metal finials, are also of a later date.

**Russia.**—A style originally Byzantine, but developed in accordance with Russian taste, continued in use in that country down to the beginning of the 19th century. (See RUSSIAN ARCHITECTURE.) Like the Byzantine of Greece and the Balkans, its churches tend toward high and slim proportions. Details, however, show wide divergences from those in Constantinople. Particularly characteristic is the decoration of dome drums and gables with a succession of small semi-circular arches, like scales, one above the other; onion domes; towers with fantastically domed tops; column shafts moulded like balusters, with simple capitals; and, on the interior, the frequent use of mural paintings instead of marble and mosaic. The result is an impression of rich and sombre mystery. The great cathedral of S. Basil in Moscow is a good example.

### ROMANESQUE ARCHITECTURE

**Origin and Development.**—Conditions in the western part of the Roman empire during the 5th, 6th and 7th centuries were chaotic. The invading barbarians from the north made Roman provinces their highway, occasionally, like the Goths and Vandals,

passing on to Africa, but usually settling in the districts which they conquered and mixing with the native stock. In the resultant confusion, the Roman material civilization died. Men of alien tradition, with pastoral and nomadic backgrounds, filled the cities of France, Spain and Italy, where the Roman buildings fell into decay and were looted of their furnishings. The new peoples born from this condition needed buildings, and especially, because of their recently acquired Christianity, churches. Yet their building traditions and skill were unequal to the task. Naturally they turned to Roman buildings for their inspiration, and their attempts to imitate them constitute the earliest Romanesque, which is well represented by certain Roman basilicae (q.v.), in which crude, new buildings were decorated with architectural details looted from Roman work and confusedly used.

Charlemagne (768-814) made a real attempt to resurrect Roman culture, and the church that he built at Aachen (Aix-la-Chapelle) was, in its day, the most advanced building in Europe. In building it, he turned to Byzantine work for inspiration, and in many ways the church strongly resembles S. Vitale at Ravenna. It is an octagonal building with two storeys of side aisles round a central domed area; the details are as Byzantine as the general scheme. This was a unique example to which later architecture owes little. A more interesting effort was made in the barbaric kingdom of the Lombards, where under Liutprand, towards the end of the 8th century, legal recognition was given to a builders' guild known as the *Maestri Comacini*. These builders attacked the building problem realistically, gave up the sterile attempt to imitate Roman work and developed forms to fit their own crude technique and ornament to express their own emotions.

It is difficult to trace the exact growth of Romanesque art during these chaotic times. It developed from various sources. In France, the influence of Roman precedents was strong (e.g., S. Jean, Poitiers, probably 6th century; complete contemporary descriptions of other lavish buildings exist). In northern Spain, there was a crude art of great vitality, sometimes known as Visigothic art. It was not, however, until the 10th century that an architecture thus engendered achieved definite form; examples from then on become increasingly numerous and important. All Romanesque architecture has certain common features. National boundaries were then non-existent and the unifying power of the Church, exerted especially through the widely spread monasteries, particularly of the Benedictine and Cistercian orders, was everywhere dominant. Monasticism was the ecclesiastical expression of the same social and political influences that produced feudalism. To cultivate the arts was a cardinal tenet of the Benedictine order, and although lay architects begin to appear in increasing numbers in the 12th century, the earlier master builders were undoubtedly monks who carried building traditions from one monastery to another, and so spread the Romanesque style. All the common factors of Romanesque architecture are the result of the attempt to build an adequately lighted, impressive church building, as richly decorated as possible, with incomplete technical skill and crude materials. Knowledge of structural engineering grew from year to year, by trial and error, through the frequent collapse of earlier buildings, but never enough to give builders complete mastery of their problem. Romanesque walls are universally heavy, usually of small stones or brick; windows and doors are almost always small and round arched; columns are short and stumpy, with heavy capitals. In the place of columns, square or clustered piers are often used to separate nave and aisles.

The church plan went through an extensive evolution. Although occasional circular churches of Eastern type are found (S. Sepulcro, Bologna, 11th century; St. Sepulchre's, Cambridge, England, 1101), it is the Roman basilica type that is dominant. Side aisles are low and frequently vaulted with groined vaults. In order to get clerestory windows, naves are made as high as the builder dared; in earlier cases they are usually roofed with wood, but increasingly the attempt was made to vault them completely in masonry. The triforium (q.v.) gallery appears between the arcades of the side aisle and the clerestory windows, sometimes occupying merely the space under the sloping roof of the side aisles, sometimes existing as a full second storey gallery. Apses

usually terminate nave and choir at the east end, and as the ritualistic requirements of the church increased, first transepts, and later minor apses, and additional chapels, were added. The interior decoration is simple, consisting merely of carved capitals of the columns of piers, steppings or simple mouldings in the arches, occasional carved panels round doorways or in other important positions, and simple horizontal mouldings separating side aisle arcade, triforium and clerestory. Lavish colour decoration is found on simple surfaces. There are extensive remains in the church of St. Benoît sur Loire, 12th century. The lower portions of the wall are painted to represent drapery, while above, groups of saints and angels are indicated in a stiff but forcefully Byzantine manner.

The Romanesque period saw the development of the Latin cross type of church plan and the complex but systematized east end or chevet (*q.v.*) consisting of an apse (*q.v.*) with the side aisle carrying around it as an ambulatory (*q.v.*) and with chapels, generally apsidal, opening from it. Significant, also, is the common use of clustered piers, carefully designed with reference to the members which they carry. A typical pier between nave and aisle is frequently of cross shape; the two longitudinal arms carry the pier arches, the projection toward the aisle carries a cross rib of the aisle vault, and the projection into the nave continues up in front of the triforium and clerestory walls to carry either a cross rib of the nave vault or the nave truss. In addition, minor members on the nave side were occasionally added under the groin of the nave vault, and if the pier arches are heavily moulded there may be subsidiary shafts under the main moulding members. In exterior design, decoration consists of simple cornices, sometimes supported by little arches and frequently with corbels (brackets), carved with human heads or leaves and the use of projecting buttresses or buttress stripes occasional wall arcading.

The typical Romanesque door, although itself small, was made a large decorative motive by stepping outward the sides and covering arch in several layers in the thickness of the wall. Each step, known as an order, was treated as a separate decorative entity. Columns, carrying additional arch mouldings, were frequently inserted in the re-entrant angles of the steps. The space between the arch and the top of the door, known as lunette or tympanum, is usually decorated with reliefs of biblical stories or the lives of saints. In addition, there is much rich foliage, frequently intermingled with birds, animals and grotesques (for the elaborate symbolism of these reliefs, see E. Male, *Religious Art of the Twelfth*

*Century in France*). Among the most common subjects and motives of this decoration are: The Last Judgment; Christ enthroned, surrounded by the four evangelists; and the Virgin, enthroned. Christ and the Virgin are usually represented within an oval frame, known as the vesica or mandorla. In the carving of capitals and running mouldings, there is frequent evidence of influence from Mohammedan textiles. The Romanesque period also saw the growth of the church tower as an integral part of ecclesiastical architecture. (See CAMPANILE and TOWER.)

The most important development of Romanesque architecture was the result of continual experimentation with vaulting. (See VAULT.) Completely stone vaulted churches were necessitated by frequent disastrous fires in wooden-roofed buildings, and the problem of counteracting the thrust, or outward pressure, of high, heavy, nave vaults without obscuring clerestory windows, was a controlling factor in Romanesque design. The barrel, or continuous vault, is found in early examples, in which the thrust is only imperfectly braced by the brutally heavy walls. This was soon abandoned in favour of the groined or intersecting vault, in which the weights and thrusts are concentrated at the piers. Intersecting vaults, themselves, brought difficulties, for the nave and aisles, being of different widths, would, in true intersecting vaults, have different bay spacings. To obviate this, the Lombards made one bay of the nave include two bays of the aisle (*e.g.*, S. Ambrogio, Milan, 10th and 11th centuries). They were followed in this by the Rhenish builders. In other localities, various types of oblong vault bays were used, and in Normandy, the sexpartite vault (*q.v.*) was invented in the attempt to combine the advantages of both schemes. The final solution came only with the pointed arch in Gothic architecture (*q.v.*). Another difficulty lay in the heavy centring or temporary timber bracing required during the construction of great vaults. To cope with this, the vault was divided into small sections by ribs, *i.e.*, independent arches, easily built. From these, centring for the intervening sections could be supported. At first ribs were only used across the nave and aisles, but, later ribs were also built under the groins (the diagonal intersections between the two surfaces that make up the intersecting, or groined vault). These still further diminished the surface for which centring was necessary at one time. The last stage in the development came with the slight arching of all of the surfaces between the ribs, so that the ribs carried the entire weight of the vault. Complete ribbed vaults of this type, with cross ribs, and

groin or diagonal ribs, came into use in several places at almost the same time. It is generally agreed that the earliest example is that over the nave of the Lombard church of S. Ambrogio, Milan, probably dating from the second half of the 11th century (Cattaneo, *L'architettura in Italia dal secolo VI al mille circa*, 1888). Other early instances exist in France at Morienval, Oise (c. 1120), and at Durham cathedral in England (1093-1133).

In the development of Romanesque architecture four historical influences are apparent. The first is a direct legacy of pagan Rome. The second is the influence of the Byzantine Eastern empire, which was known in the western world through the wide circulation of manuscripts, jewel work, ecclesiastical furniture and carved ivory, all made in Constantinople, and also by means of the occasional use of Syrian masons and Greek decorative artists. The third is the influence of the builders' own northern background, shown in a certain structural vitality, and the use of ornament of a bold and almost savage intricacy. The last is a direct influence from the Near East, due to commerce in oriental textiles and memories brought back by the crusaders. The various ways in which these influences were intermingled and the varying materials occurring in different localities necessarily produced a series of important local styles which, with their chief characteristics, may be summarized as follows:

**Lombard.**—This style shows great structural genius, with development of the arcaded cornice, the buttress strip and the campanile. The carved ornament is crude, with much use of grotesques and interlaces borrowed from the Byzantine. (S. Ambrogio, Milan; S. Michele, Pavia.)

**Tuscan and Central Italian.**—A style developed by skilled decorators, showing little structural initiative; the buildings follow Roman basilican types. Byzantine influence causes the use of coloured marbles, especially in bands alternately dark and light. Decorative arcades (*q.v.*) and colonnades (*q.v.*) are developed to a high degree, as in the fronts of Pisa (c. 1020) and Lucca (12th century) cathedrals.

**South Italian and Sicilian.**—Here the style is a confused mixture of Lombard, Byzantine, Roman and oriental influences. There is a rich use of mosaic, which in the Capella Palatina in Palermo and in the apse of Monreale cathedral, both of the late 12th century, achieves its highest possibilities. In Apulia, strong Lombard characteristics are evident, as in Troia and Bitonto cathedrals.

**Provence.**—The barrel vaulted naves, low proportions, rich entrances are characteristic, and all decorative work reveals the attempt to copy, with very little change, the motives of Roman ornament. This is the most classic of the Romanesque styles in France (e.g., S. Trophime, Arles).

**Aquitaine.**—Unique in its adoption of Byzantine structural ideas, with the consequent use of the dome on pendentives. Its greatest monument, S. Front at Périgueux (begun 1120), in plan strikingly resembles S. Mark's at Venice. The pointed, scaled, exterior spire and dome forms are characteristic, as also the great façade richness through the use of many tiers of crude wall arcading filled with sculpture. Pointed arches are occasionally used, as in Cahors cathedral.

**Auvergne.**—Byzantine, Roman and Lombard influences are all present, and barrel vaults, groined vaults and domes are found. There is much use of polychrome masonry for exterior decoration. This style is important because of its vaulting experiments and its elaborate development of the chevet (e.g., N. Dame-du-Port, Clermont-Ferrand, cathedral at Le Puy en Velly).

**Burgundy.**—Here there is evidence of strongly-marked structural genius, coupled with interesting adaptations of Roman decorative forms (e.g., cathedral at Autun). Very elaborate entrance doors are frequently found, and occasionally enclosed porches, as in the Abbey of Vézelay.

**Normandy.**—Little Roman or Byzantine influence is found in Normandy. The Lombard influence is strong owing to the fact that an abbot of Pavia, Lanfranc, was in charge of Norman monasteries in the 11th century. The ingenious experiments in vaulting reached their climax in the Abbaye aux Hommes and the Abbaye aux Dames in Caen (last quarter 11th century), where rudimen-

tary flying buttresses first appeared, and in Durham cathedral. The architectural forms are used for decorative purposes (arcades, buttresses, etc.) and the highly finished geometric ornament is characteristic. The Romanesque architecture of England, known as Norman, is largely of this type. An English peculiarity is enormous length in church plans, as in Ely and Peterborough cathedrals.

**Rhineland.**—Here the Lombard influence is dominant. The development of height in church interiors is noteworthy, and the churches frequently have an apse at each end. The use of many towers resulted in fantastic silhouettes, and the carved ornament is often vividly grotesque (e.g., cathedrals at Mainz and Speyer, Church of the Holy Apostles, Cologne).

**Spain.**—There was vital development in Spain at a very early period (Visigothic art). Later manifestations show strong Moorish influence in geometric ornament and conventionalized foliage, and unusual skill in figure sculpture. Through the great church of Santiago at Compostella, one of the most thronged pilgrimage spots of the period, and the existence of a brilliant school of manuscript decoration, this style was of the greatest importance in the development of decorative sculpture throughout Europe. (See Male, *loc. cit.*, and Arthur Kingsley Porter, *Sculpture of the Pilgrimage Roads*, 1923.)

The general effect of Romanesque architecture, both structurally and decoratively (except in southern Italy), is that of power, incomplete achievement and sombre gloom. Its grotesque ornament, often full of a perverse cruelty, instinct with a sense of terror, expresses a mentality under terrific nervous strain—the same emotional instability revealed in the popular fear of the end of the world in the year 1000, and later expressing itself in such extraordinary manifestations as the Children's crusade. Whatever the symbolic or religious explanation of these carvings may be, they are one of the best expressions of the time. The entire population of Europe, struggling to create an as yet inchoate civilization and hampered by feudalism, was confronted by the remains and the tradition of the Roman world. They could not produce buildings or art comparable to those of Rome, and this fact engendered in them, especially in those who were artists, a profound sense of inferiority and frustration, which could only find expression in such an art as that which built the moving mystery of St. Sernin at Toulouse, or painted the savage Last Judgment of Torcello cathedral. (See also ARCHITECTURE.)

**BYZANTINE ART** takes its name from Byzantium, the Greek city on the Bosphorus of which Constantine the Great made a capital in A.D. 324. For the next 1,100 years, Constanti-

nople was the centre of the Greek civilization that produced Byzantine art. Signs of a forthcoming revolution in plastic ideas occur before the foundation of Constantinople, such as the four porphyry emperors set in an outer wall of S. Mark's at Venice (c. A.D. 300), whose simple planes bring out the quality of the material with a new technique. But it is characteristic of the transitional period that these figures are still scowling, close-cropped soldiers, and it was only after Constantinople had received its name that the imperial semblance itself was composed in accordance with the new aesthetic principles. On the coins produced not only at Constantinople but by the other Greek mints, the new type may be seen in its purity, while western coins attempt the imitation of the Greek style. In portrait sculpture, enough fragments remain to show that the movement there was parallel. Religious art, meanwhile, gradually divested itself of the well-worn stock of formulae, taken over from antiquity, common in Early-Christian sarcophagi and wall paintings. It took, however, two centuries for Byzantine principles to extend to the whole field, religious art included, and even so they only triumphed completely in the Greek parts of the empire.

**Characteristics.**—Regard for the material and stylization by simplifying outline and colour are characteristics of the Byzantine architect, sculptor, enameller and weaver. Coloured marbles are widely used; mosaics composed of glass cubes enrich wall-surfaces; translucent enamel, pearls and cabochon stones are set in simple mounts; coloured and figured silks appear in costume as well as in decoration. The Byzantine artist contrives so to choose and handle his material that it perpetually looks fresh and living, even in a modern museum.

#### THE EARLY PERIOD: CONSTANTINE TO JUSTINIAN

Of the surviving vestiges of the 4th and 5th centuries not all, by any means, are Byzantine, but in the 6th, the triumph of Byzantine ideas is recorded in S. Sophia at Constantinople and in numerous well-known monuments at Ravenna and elsewhere. However, the 4th century was the turning point, as is shown by a gilt bronze head, probably representing Constantius II. (A.D. 361), in the National Museum at Budapest (Pl. I., fig. 1). Here, the flat, simple planes, the expression of the face, the frontal pose, the treatment of the hair, the exaggerated eyes, the diadem and the drapery are essentially Byzantine; this bust stands quite outside the antique, and belongs to a new order which was to endure for many centuries.

**Unity of Style.**—Unity of style underlies surface-changes throughout the history of Byzantine art. S. Fosca at Torcello shows the application to architecture of the principles of mass-composition, analogous to those that transformed sculpture in the 4th century. A careful study shows that the wall-surface of the arcade catches the light as one solid mass broken only by the shadow of the openings. The supporting columns are smaller than the classical canon would demand and allow the wall-space behind to play its rôle. In all Byzantine building the exterior surfaces, including the roofs, are presented as simple planes. Even the arcade, which often precedes or surrounds churches, does not break up the wall-surface after the manner of a classical portico. In Byzantine buildings in Ravenna and elsewhere in Italy this is not always evident, as mouldings and other ornaments have frequently been added in comparatively recent times.

These principles of mass composition are also strikingly illustrated in interior design; for example, in S. Sophia. Just as in S. Fosca the eye is led by the sloping roof of the exterior gallery up to the gable ends which, in turn, lead up to the central roof, so in S. Sophia do the minor conches, sunk into the walls supporting the semi-domes, lead to the semi-domes and thence to the cupola. No such grouping of surfaces and spaces occurs in classical architecture. (See BYZANTINE AND ROMANESQUE ARCHITECTURE.)

**Decoration.**—The glass mosaics which decorated the upper walls and vaults of the typical Byzantine ecclesiastical interior tended more and more to become a flat surface of colour, symmetrically adorned. This tendency may be observed, in the 5th century, eliminating what remains of the classical mosaic tech-

nique; in the 6th it triumphs. Green, blue and gold dominate in the 4th and 5th centuries; white, purple and gold in the 6th. Early wall-mosaics of the 5th and 6th centuries survive at Ravenna; those in S. Vitale representing Justinian and Theodora are particularly well known; these, unfortunately, have been radically restored. The 6th century work at Parenzo has also suffered. Purer examples of the 5th century survive in Milan (S. Aquilino), and also, more abundantly, in the magnificent dome of S. George and in the Parascheve at Salonika. The Salonika examples are precious witnesses to the quality of early Byzantine mosaic, which cannot be appreciated at Ravenna.

The floor, like all the other surfaces of a Byzantine building, is treated as part of the composition. The colour scheme of the mosaic pavement is duller than that of the surfaces above: earthy browns and yellows are enlivened by black and white, by red and green, and rarely, as at Aquileia, by a few tesserae of coloured glass. On this pavement are set the great white cubes of the bases from which rise columns of grey-green cipollino, red porphyry or dark green verde antico. The lower walls are wainscoted with slabs of similar marbles, to which are often added red cipollino and other marbles, the veins of which are disposed in symmetrical designs. Between the zone of coloured marbles and the mosaic runs a white line of impost and capitals. Doors are plated with bronze, and enriched with scrolls in relief or with silver inlay. In such a decorative system, built up of precious materials, the painted plaster of frescoes can have no place except where the community is unable to afford anything better.

The system that came to culmination in S. Sophia may also be studied in SS. Sergius and Bacchus in Constantinople; in S. Sophia in Salonika and in S. Vitale at Ravenna. Fifth and 6th century basilicas in which the same principles are applied to a simpler scheme of construction exist in Ravenna, Grado and Parenzo; at Salonika; in Asia Minor, Syria, Palestine and North Africa.

**Sculpture.**—Little sculpture in the round remains from the early period. Indeed the general scheme of the Byzantine church does not require figure sculpture. The remains are chiefly fragments of imperial portraits. Plate I., fig. 5 shows a highly accomplished head in the Castello at Milan, which may represent the Empress Theodora. With the exception of a porphyry head at Venice mentioned below, this is the last Byzantine imperial portrait in the round known to us. We have some 30 pieces of 4th century imperial sculpture, of which may be mentioned: a colossal bronze head, probably of Constantius II., in the Conservatori Museum at Rome, a colossal bronze statue, perhaps of Valentinian I., at Barletta, the reliefs on the base of the obelisk of Theodosius in the Hippodrome at Constantinople, and a porphyry torso in the Archbishop's palace at Ravenna (possibly 5th century). Three female heads in chalky white marble, one in the Louvre and two in Rome, probably represent the Empress Ariadne (c. 500), and are inferior to the heads reproduced on Plate I. Early Byzantine religious sculpture is even rarer. A series of busts of prophets from Asia Minor, now in the Constantinople museum, show a tolerable 4th century Byzantine style, and a white marble head from Ephesus in the Vienna National Museum (Pl. I., fig. 6) is one of the very rare examples of quality. A group of sarcophagi apparently carved in Asia Minor, and taking their name from one found at Sidamara, show Byzantine characteristics in some of the later examples. Small figures representing the Good Shepherd in the Constantinople museum may also be mentioned. Egypt, then a province of the empire, has given us carved tombstones and a certain amount of decorative sculpture, which can only be dated by reference to 5th and 6th century monuments in the capital. The flat carving of the tombstones is a provincial variation of the Constantinople style. Small figures disporting themselves among the architectural ornament of doors and windows show a more local manner with a predilection for the nude treated in a rather jocose spirit. The dry soil of Egypt has also preserved early wood-carving. In wood and ivory-carving, as well as in the woollen textiles, great numbers of which survive, showing a wealth of decorative motive, this Copto-Byzantine art merges into the early Islamic art of Egypt.

**Decorative Arts.**—In the middle of the 6th century, the Chinese monopoly of silk-growing was broken, and silk-weaving became a Byzantine industry. The Cluny Museum possesses a typical textile of this period, showing a chariot-racer in the hippodrome. This scene, which was repeated in the other medallions, is perfectly symmetrical. The style is that of dated consular diptychs of the earlier 6th century. The spandrels, however, have a Persian look about them. Thus, at the very inception of Byzantine silk-weaving, a phenomenon, later common, appears: the choice of Sassanian subjects. To what extent the result can properly be described as Oriental is uncertain. No known textiles can be proved to be Sassanian, and few of the Sassanian monuments, such as rock-reliefs and figured silver dishes, show the balanced composition characteristic of Byzantine textiles. Such compositions do appear on the reverses of the 4th century Byzantine coins and, for instance, on the 4th century silver discs of Valentinian II. (at Geneva) and of Theodosius (at Madrid). The Cluny charioteer silk is lead-blue shot with red, the design being in tawny yellow. It has been supposed that this rather simple scheme of colour is characteristic of Constantinople, and that brighter and more varied hues mark Alexandrian manufacture. However, other textiles in which simple, sombre colours prevail have also been found in Egypt. Fragments illustrating these may be seen in most of the big museums and church treasures.

Ivory carving takes on new life in the 4th century. Panels cut out of large tusks were carved with Christian, secular and even Pagan scenes. A series of dated consular diptychs, of which the earliest is that of Probus (406) at Aosta, and none later than 541 when the consulate was abolished, assist in dating other carvings. The qualities of the material lead the ivory carver to use round contours, and perhaps for this reason, even in the 6th century, his work keeps a superficial resemblance to the antique. The most important example of this art is the throne of Maximian at Ravenna, probably made between 545 and 556. (Pl. II., fig. 5.)

In silver plate, the Byzantines allowed the metal to produce its effect in simple masses, instead of covering it with the typical Roman naturalistic ornament. Plain round, square and triangular dishes with pearl borders, and large votive discs are typical of the 4th century. For the 5th and 6th we have mostly church plate, much of it bearing religious scenes. Some of the best 6th century examples appear to have been made in Syria. The compositions on them, although symmetrical, are often dramatic, and recall paintings on Syriac manuscripts such as the *Rabula Gospels* at Florence (dated 586).

Few illuminated manuscripts of this period have come down to us. Two Virgils in the Vatican and one in Milan are probably of the late 4th century or of the early 5th, and have about them little that is Byzantine except a vivid scheme of colouring which Wickhoff has conveniently called impressionistic. The *Rabula Gospels* are not only dated but are known to have been written in Mesopotamia. Their artistic merit is small, but they help to date better examples: a codex preserved at Rossano, and the Sinope fragment in the Bibliothèque Nationale in Paris. These illuminations are as gorgeous as mosaics: the parchment is stained a deep imperial purple, the lettering is gold or silver and the other colours are intense. White is much used as in 6th century mosaics. A *Genesis* in Vienna and the charred remains of the *Cotton Bible* in the British Museum show a style like that of the Rossano codex.

Sixth century representations of imperial personages in mosaic (S. Vitale) or sculpture, on ivory carvings and coins, display masses of heavy jewellery and ropes of enormous pearls. Examples of such jewellery exist: gold earrings with pearl, garnet or sapphire pendants, and gold and silver gilt brooches enriched with stones, paste or enamel. Votive crowns hung over the altar of S. Sophia, perhaps not unlike those preserved in the treasure at Monza and in the Cluny museum. The gold circlets are studded with sapphires, garnets, emeralds and pearls, and long pendants hang from them. The Byzantines never cut precious stones into small regular facets which, while making the jewel sparkle, detract from the colour and the quality of the stone. Very few existing

examples of enamel (*q.v.*) can be dated as early as the 6th century.

#### THE MIDDLE PERIOD: 8TH AND 9TH CENTURIES

The obscure 7th century seems to be a period of transition. The coins of Justinian II. (d. 711) are designed in a new flat style.

**Representations of Royalty.**—From the foundation of Constantinople to the beginning of the reign of Phocas (602–610) rulers are, with very few exceptions, represented as beardless youths. In the 7th century, mature emperors are shaggy, bearded warriors. From the 8th century onwards, the reigning emperor has a carefully trimmed, pointed beard, long hair and an oval head tapering to the chin. The princes often appearing on the reverses of coins are beardless. The imperial costume is no longer classic or military, but consists of long, stiff, jewelled robes usually covered with pearls in a lozenge pattern. The type of royalty thus created pervades not only the empire but, in the course of the middle ages, all Europe. The extreme rarity of human representations in any other medium for the whole middle period makes it necessary to have recourse to coins in order to bring out this most significant change. A well-preserved silk textile in Sens Cathedral, the shroud of S. Victor, traditionally held to have been given by Willicarius (d. 769), presents a lion-tamer whose oval head, long hair and lozenged breast-piece closely resemble representations on the coins. This shroud is of a rough texture; on a background of tawny yellow the design stands out in greenish blue enlivened by gold in the lion-tamer's hair and white dots in the border. Even on textiles, human shapes are rare, but the type of animal seen on the shroud of S. Victor and on other silks, some of which are associated with the 8th century, appears on many carved slabs and on an enamelled ewer at S. Maurice d'Agaune, which, according to tradition, was a gift of Charlemagne (d. 814).

**Sculpture in Relief.**—The slabs found on Greek territory, in Athens, Salonika and Constantinople, are undated. A characteristic example in Salonika is reproduced on Pl. I., fig. 4. In the West, some slabs of corresponding style are dated; for instance, one at Cividale bears the name of Sicvald, Patriarch of Aquileia (762–776). The interlace, which in the East is sparsely used (*see* the shroud of S. Victor at Sens), tends in the West to crowd out animal shapes. On the Salonika slab, there is a new variety of tree ornament with simple trilobed leaves. This type of flat relief showing beasts, birds and monsters, often combined with foliage or with interlace borders and crosses, is almost the only existing sculpture of the 8th and 9th centuries. Other things must have existed, for it is recorded that Constantine V., Copronymus (reigned 741–775) had statues made of himself and his empress, as did also Philippicus (711–713) and Constantine VI. (780–797). High up on a mighty cliff in north-eastern Bulgaria there is a colossal relief of a horse and rider, a lion and a hound, accompanied by a long Greek inscription, as yet incompletely deciphered, in which occur the names of Krum, Sublime Khan of the Bulgars, of his son Omurtag and of the Byzantine emperor Nicephorus I., who was defeated and slain by Krum in 811. The manner in which this magnificent relief is placed on the face of the cliff may recall Sassanian rock-sculpture. In character it is more like the riders on the famous silk from Mozac now in the Lyons museum, which is Byzantine. This carving, probably by a Greek, is in higher relief than are the slabs mentioned above and its planes are more rounded. In the museum at Constantinople, in Top Kapu Gate in the same city, and in the Byzantine museum at Athens there are fragments of beasts in similar high relief though on a small scale. The art of the middle period is thus known principally by carved slabs and textiles.

The gold ground of the few remaining mosaics of this period in the East, such as those in the apse and bema (*q.v.*) of S. Sophia in Salonika and in the bema of S. Irene in Constantinople, is tawnier than the earlier golds. In Roman work of the early 9th century the gold is also tawny although far inferior to the Eastern.

The distaste for human representation which characterizes the middle period culminates in the official prohibition of sacred im-

### BYZANTINE DECORATIVE ART OF THE 4TH–11TH CENTURIES

1. Carved ivory casket known as the Veroli casket. 10th–11th centuries
2. The Urn of Saint Rinaldo in the cathedral, Ravenna
3. 4th century carved ivory panels representing Adam in the Garden of Eden and St. Paul with other figures. Museo Nazionale, Florence
4. 6th century diptych of Romanus II and his wife, Eudocia. About A.D. 945. From the Cabinet des Médailles, Paris
5. Ivory panel carved in bas-relief, from the throne of Saint Maximian (6th century) in the cathedral, Ravenna
6. Ivory panel depicting Romanus II and his wife, Eudocia. About A.D. 945. From the Cabinet des Médailles, Paris

ages. From 726 to 842, with interludes, not only was the making of images a punishable offence, but existing images were destroyed or covered with whitewash. The seated Virgin in the apse of S. Sophia at Salonika is believed to have been executed in one of the pauses in the iconoclastic struggle under Irene (787-797). If this dating is correct, a decorative system, the 11th century examples of which are numerous and well known, had been mastered before the 8th was over. The semi-dome of the apse is covered with a gold ground, on which stands out alone the figure of Our Lady holding the Child. Here again, the Byzantines let simple surfaces play their reasoned part in the composition of interiors.

**The Decorative Arts.**—Perhaps because the supply of tusks was cut off from Constantinople by the Arab wars, very few carvings survived that can be assigned to the 8th or 9th century. A group that takes its name from the Veroli casket (Pl. II, fig. 1) in the Victoria and Albert museum, London, is by some supposed to be of this period, but more likely dates from the 10th and 11th centuries. Few painted manuscripts can be attributed to this period; these show the same style of fantastic animal decoration met with on slabs and in textiles, but in coarse, washy colours. Among the very numerous manuscripts of the Carolingian age in the West, there are in all probability types which represent imitations of Eastern originals now lost.

The origins of the cloisonné enamelling technique so much used by the later Byzantines are lost. Descriptions of the altar given by Justinian to S. Sophia appear to refer to such enamels, and a small panel at Poitiers may be the central part of a reliquary sent by Justin II. about 569 to S. Radegonde. The Beresford-Hope cross in the Victoria and Albert museum and a cross-shaped box in the Vatican have translucent enamels of brilliant colour and quality. In them the designs made by the cloisons are clumsy, and there are stylistic and iconographical reasons for assigning to them an early date, perhaps the 7th century. They are surely earlier than the highly accomplished convex enamels on the ewer of Charlemagne at S. Maurice d'Againe, which tradition and style agree in dating somewhere about 800. In the Camara Santa at Oviedo there is a cross with enamels not unlike those in the ewer, but perhaps earlier.

No outstanding Byzantine plate or jewellery is certainly of this period. Western treasures which contain Carolingian goldsmith's work, ivories and illuminated manuscripts in plenty preserve many Byzantine textiles and a few enamels. We know that the West could not weave silk, and was unable to produce enamels of the quality attained by Eastern artists, but it appears to have been satisfied with its own ivory carving, goldsmith's work and illumination.

### THE LATER PERIODS

After the fantastic creatures and ornament of the 8th and 9th centuries, and without any transition, comes the art, at once refined and realistic, of the Macedonian revival. The old Greek taste for representation again prevails. A series of ivory carvings, manuscripts and enamels, which there is solid ground for dating, presents a small, gentle world in which every grade of the celestial and terrestrial hierarchies has its place.

**Examples of the Later Style.**—A suggestion of this change may be caught on one of the coins of Basil I. (867-886) and the new style is clearly seen on a few pages bound into the celebrated Gregory of Nazianzus manuscript in the Bibliothèque Nationale, Paris. Here, the imperial portraits can be dated between 879 and 886. These paintings and a sketch revealed by flaking on one of the pages have delicacy and distinction. There are few datable monuments between these pages and the Romanus and Eudocia ivory panel in the Cabinet des Médailles (Pl. II, fig. 6) which has recently been shown to represent Romanus II. and his first wife, who died 949, and not Romanus IV. (1067-1071). Thus one of the few dated ivory carvings is the most beautiful of all and represents both divine and worldly persons. Many ivories are closely related to the Romanus panel in style, but few approach it in quality. The triptych, such as the Harbaville ivory in the Louvre and the Borradaile in the British Museum, makes

its appearance. It is covered with figures of Our Lord, Our Lady, the apostles and other saints in a great variety of costume, imperial, military, ecclesiastical and monastic; a precisely defined hierarchy like that described in the contemporary writings of Constantine Porphyrogenitus. As may be seen in the Romanus ivory, features and limbs are delicate and in correct proportion, unlike those of the 6th century carvings, which are somewhat burly. Where there is exaggeration it is in attenuation and elongation: an almost effeminate elegance.

This style in metal-work may be seen in a gilt bronze triptych in the Victoria and Albert museum and in a beautiful bronze relief in the museum at Philippopolis in Bulgaria, as well as on an enamelled reliquary at Limburg-on-the-Lahn (probably between 948 and 959), showing a composition similar to those in the ivories. Of the few illuminated manuscripts that can be assigned to the 10th century, Grec 70 in the Bibliothèque Nationale has paintings in much the same spirit. The famous "Parisinus," Grec 139, in the same library, is characterized by pseudo-antique style. A marvellous collection of hard stone vases, glass and rock-crystal vessels, the mounts of some of them adorned with enamels (Pl. I, fig. 8) or with rich and delicate filigree tracery, a great deal of which is probably of the 10th century, exists in the treasure of St. Mark's at Venice.

No 10th century mosaics are known except the floral decoration in the Mihrab of the Mosque at Cordova, executed by Greeks imported for the purpose by Abd-er-Rahman III. (929-961). Numerous marble slabs, used in galleries, choir enclosures and even in windows and fountains out of doors, survive, mostly re-employed in later buildings in Constantinople, Athens, Salonika, Mt. Athos and Venice. Some continue the animal decoration of an earlier period, but the animals have become tame, round and gentle. Most of these slabs, however, are ornamented with interlaced strap-work and rosettes carved in a peculiar S-shaped profile. Figure sculpture is rare, but a marble roundel set in the wall of a house in the Campiello Angaran in Venice bears a relief of an emperor, about half life-size, who may be of this period. Basil I.'s famous church, the Nea, has vanished, and surviving architecture of the 9th and 10th centuries is on a humble scale. A superb porphyry head in the round on the parapet over the west porch of S. Mark's is certainly Byzantine, and very probably late 10th century. Some magnificent silk textiles, several of which are happily dated by woven inscriptions, show much the same change as that seen on the slabs. Animals, birds and monsters are still represented, but in another spirit, more often *passant* than *rampant* and their ferocity is rather that of menagerie beasts behind bars. The weaving is finer and the colours more delicate.

The art of the 11th century is richer than that of the 10th. Here again, the change comes out in a coin; the gold nomisma of Constantine VIII. (1025-28). The portrait of this monarch on the Exultet roll at Bari (Pl. I, fig. 9) shows an aggressive personage far removed from the benign and decorous court represented on the ivories discussed above. Figures are no longer small, delicately proportioned, and nicely arranged against a spacious background, but tend to spread out over the field. Heads grow too big for their bodies. There is a suggestion of high living about these fleshly shapes, to be expected in the somewhat scandalous court of Constantine VIII., his daughter Zoe and her numerous husbands. Towards the end of the century, attenuated figures again become fashionable.

**Mosaics.**—After 400 years for which only enough scraps of mosaics are left to show that the art did not die out, we come, in the 11th century, to a rich series. The greatest uncertainty prevails as to their chronological order. However, S. Sophia at Kieff, which still contains important mosaics, was founded in 1037 or 1038, and its decoration was probably not much later. The well-preserved cycle at S. Luke in Phocis is very near the Kieff examples in style; those at Daphni near Athens are probably later. In the Greek Islands and in Asia Minor there are less extensive remains. Greek artists also worked in Venetia and at Trieste. An instance is the praying Virgin in the apse of Murano cathedral, which is a characteristic 11th century composition, the

single figure on its ground of gold peppered with red and black cubes standing in the exact axis of the church as the point of focus for the eyes of the congregation.

Church pavements, such as those of Venice and Murano, are rich, and more complicated and heterogeneous than those of the 6th century, containing, besides stone mosaic and opus sectile, re-employed marble slabs. A few low reliefs representing the praying Virgin, which doubtless once decorated the walls of churches, have recently come to light. The most beautiful of these was discovered at Salonika (Plate I, fig. 3).

**The Decorative Arts.**—The arts of the goldsmith and the enameller continue to flourish in the 11th century. At a period not easily determined, perhaps only in the 12th century, the designs of the cloisons become rectilinear and perfunctory. Here, as in the apses, the figure is backed by a flat gold ground. The colours are: a brilliant translucent green never equalled in Western work, a sub-translucent marine blue and opaque but rather nacreous whites, yellows and reds. The purples common in earlier work become rare.

In painted manuscripts also gold grounds occur frequently, and an elaborate head-piece in brilliant colours almost suggesting enamel is common. These head-pieces are usually found in books of the Gospels, opposite full-page portraits of the Evangelists. Psalters such as one in the British Museum dated 1066 are abundantly illuminated with small marginal paintings, some of them illustrating scenes of everyday life. Profane subjects, treated with evident enjoyment, are frequently found in other religious manuscripts, as well as in treatises on the chase and histories. Textile designs tend to grow more mechanical and conventional than in paintings. There still remain examples of the best of the rare late Byzantine examples of tapestry weaving. Ivory carving dies out: no example of the first quality can well be attributed to the later 11th or 12th centuries, but carved steatite panels come into favour.

**The 12th to the 15th Centuries.**—The 12th century produces no new movement of importance; it is significant that the imperial gold coinage, which had set a standard for the world since the time of Augustus, becomes corrupt as early as the reign of Michael VII. (1071–78) and never recovers. Even silver is debased, and the artistic merit of coins deteriorates. The 13th century, broken by the Latin occupation of Constantinople, is obscure and poverty-stricken. For the 14th we have the dated mosaics of Kahrié Djami at Constantinople, which mark a definite breach with the principles of Byzantine monumental decoration. Their picturesque qualities have led some to see in them Italian influence. The same may be said of numerous frescoes at Mistra and throughout the Balkans, and of the small portable mosaics, composed of cubes of solid gold and semi-precious stones, of which a few brilliant examples survive in Western museums. The only monuments left of any interest by the 15th century are a few manuscripts with imperial portraits in which velvety but coarse reds enliven mediocre drawings.

The later arts of the Orthodox countries have kept Byzantine iconography alive to the present day, but they lie outside the scope of the present article. (See also PERIODS OF ART.)

**BYZANTINE MUSIC.** The name Byzantine is usually given to the music of the mediaeval Greek Orthodox Church. Our knowledge of it rests partly on the writings of theorists, partly on the hymns themselves preserved in liturgical manuscripts. The earlier musical signs or neumes have survived from the 10th century A.D., but their exact interpretation is not yet possible. In the 13th century the Round or Hagiopolitan notation was invented, which can be deciphered. The signs expressed intervals; the initial signature showed the Mode and gave the starting-note. Byzantine music was vocal and was sung by a professional cantor or by a trained choir in unison. No instruments were used in the Greek Church; but at the Palace of the Emperors at Constantinople there were two organs in the 15th century; and they were always used to accompany the choir on state occasions.

St. John of Damascus, in the 8th century, is said to have given Byzantine musical theory a definite form. Possibly he fixed more accurately the eight mediaeval modes, which were common to the Eastern and Western churches, and exemplified them in his own compositions. It is likely that many of the simpler melodies, which have come to us in the Round notation, had been handed down with slight variations from the time when most of the hymns were written—the poet being also the composer—that is, from the 8th, 9th and 10th centuries.

We cannot say with certainty from what sources the Eastern Church derived her music before the 8th century. It is usually assumed that the prevalent Graeco-Roman type of melody formed the basis in early Christian times, with a free inclusion of Hebrew tunes, borrowed along with the Psalms and Canticles. But the other branches of the Christian church in the East, particularly the Syrian and, later, the Armenian, probably contributed something also. After the conversion of the East Slavonic races, their churches took over the Byzantine musical system.

Byzantine music had no fixed rhythm or regular division into bars or measures. The tune follows the words according to the stress accents, ignoring the ancient quantities of the vowels, and as the text is nearly always rhythmical prose (like the Psalms in

GREEK HYMN WITH MUSIC IN THE ROUND SYSTEM OF NOTATION

As no instruments were used in the Greek Church, Byzantine music was entirely vocal. It had no fixed rhythm or regular division into measures

both the Greek and English Bibles) the total effect is a rather lively and melodious recitative rather than a tune in the modern sense.

The Modes are numbered in a different order from the Gregorian, which they otherwise resemble, and exhibit several by-forms. The classification as Authentic and Plagal had more theoretical than practical value. The normal types require the following initial and final notes. Authentic—Mode I., a or d; Mode II., b or g, Finalis e; Mode III., c' or a, Finalis f; Mode IV., theoretically d', but usually g. Plagal—Mode I., d; Mode II., Pl. e; Mode III., Pl. (also called Barys or Grave Mode) f, rarely low B-flat; Mode IV., Pl. g. All these seem to have used the diatonic vocal scale with Just Intonation.

In the 15th century Byzantine music becomes more ornate and florid, while the notation adopts many subsidiary signs, as guides to execution and expression. Some of these had already been invented by the famous singer John Cucuzeles about 1300; and this ornate notation is often called Cucuzelian. In the 16th and early 17th centuries the art declined; and the notation was only known to a few precentors. A revival took place about 1670, the work of a school of composers, whose centre was the Patriarchal church at Constantinople. These musicians were accustomed to Oriental music, and some of them composed Turkish songs. Consequently, though the notation does not differ greatly from the 15th century, the spirit of the music is decidedly Eastern; and the Turkish scales, with their irrational intervals, were probably employed, at any rate in new compositions.

This Graeco-Oriental school lasted until 1821, when Chrysanthus, an Archimandrite, introduced a simplified notation, also consisting of interval-signs, in which the music could be printed. Although Chrysanthus had studied Western theory, he accepted the Oriental scales and invented symbols to describe them. His principles seem to have been too complicated for general use; and complete uniformity of rendering was not secured. The Chrysanthine notation is still in use; and the traditional manner of singing, often painfully nasal, with a drone or holding-note kept by one or two voices, may be heard in most of the smaller Greek churches and monasteries.

It is a common mistake to believe that this modern system is the same as mediaeval Byzantine music. Since 1870 some of the larger city Churches have introduced four-part unaccompanied singing, perhaps under Russian influence. But more recently there has been a set-back in favour of the Chrysanthine usage.

Example of a mediaeval Byzantine hymn (about 1400 A.D.), viz.:—

First Ode of a Canon from ms. No. 1165, at Trinity College, Cambridge. Mode III. Plagal (Barys or Grave) from f, Finalis f.

(1) Ἀι - σω - μεν τῷ κυ - ρί - ω (2) τῷ βυ - θί - σαν - τι  
 πᾶ - σαν τὴν δύ - να - μιν (3) Φα - ρα - ὦ ἐν θα - λάσ - σῃ  
 (4) ἐ - πι - νί - κη - ον ᾧ - δὴν (5) δ - τι δε - δόξ - ας - ται.

Translation. "Let us sing unto the Lord, who sank all the might of Pharaoh in the sea, a song of victory, for He hath triumphed gloriously."

**BYZANTIUM**, a Greek city on the shores of the Bosphorus, occupying the most easterly of the seven hills of modern Constantinople. It was founded by Megarians and Argives under Byzas about 657 B.C., but destroyed in the reign of Darius Hystaspes by the satrap Otanes; it was recolonized by the Spartan Pausanias (479 B.C.). Its situation was remarkable for beauty and security. It controlled the Euxine grain trade; the depth of its harbour rendered its quays accessible to vessels of large burden; while

the fisheries were so lucrative that the curved inlet near which it stood became known as the Golden Horn. The population was partly Lacedaemonian and partly Athenian; it was thus a subject of dispute between these States, and was alternately in the possession of each, till it fell into the hands of the Macedonians. About seven years after its second colonization, the Athenian Cimon wrested it from the Lacedaemonians; but in 440 B.C. it returned to its former allegiance. Alcibiades, after a severe blockade (408 B.C.), gained possession of the city through the treachery of the Athenian party; in 405 B.C. it was retaken by Lysander and placed under a Spartan harmost. It was under the Lacedaemonians when the Ten Thousand, exasperated by the conduct of the governor, made themselves masters of the city, and would have pillaged it but for the eloquence of Xenophon. In 390 B.C. Thrasybulus expelled the Lacedaemonian oligarchy, and restored democracy and the Athenian influence.

Byzantium joined with Rhodes, Chios, Cos, and Mausolus, king of Caria, in throwing off the yoke of Athens, but sought Athenian assistance when Philip of Macedon advanced against it. The Athenians under Chares suffered a severe defeat from Amyntas, the Macedonian admiral, but in the following year gained a decisive victory under Phocion and compelled Philip to raise the siege. The deliverance of the besieged from a surprise, by means of a flash of light which revealed the advancing Macedonian army, has rendered this siege memorable. As a memorial of the miraculous interference, the Byzantines erected an altar to Torch-bearing Hecate, and stamped a crescent on their coins, a device which is retained by the Turks to this day.

During the reign of Alexander, Byzantium was compelled to acknowledge the Macedonian supremacy; after the decay of the Macedonian power it regained its independence, but suffered from the incursions of the Scythians. The losses which they sustained by land roused the Byzantines to indemnify themselves from the vessels which crowded the harbour, and the merchantmen which cleared the straits; but this had the effect of provoking a war with the neighbouring naval Powers. The exchequer being drained to buy off the Gauls about 279 B.C., and by the imposition of an annual tribute of 80 talents, they were compelled to exact a toll on all the ships which passed the Bosphorus—a measure which the Rhodians avenged by a war wherein the Byzantines were defeated.

During the first years of its alliance with Rome, Byzantium held the rank of a free confederate city; but, having sought arbitration on some of its domestic disputes, it was subjected to the imperial jurisdiction, and gradually stripped of its privileges. The Emperor Claudius remitted the heavy tribute which had been imposed on it; but the last remnant of its independence was taken away by Vespasian, who taunted the inhabitants with having "forgotten to be free." The city was besieged and taken (A.D. 196) by Severus, who destroyed it, demolished the famous wall, and put the principal inhabitants to the sword. This overthrow of Byzantium was a great loss to the empire, since it might have served as a protection against the Goths, who afterwards sailed past it into the Mediterranean. Severus afterwards relented, and, rebuilding a large portion of the town, gave it the name of Augusta Antonina. It had scarcely begun to recover its former position when, through the capricious resentment of Gallienus, the inhabitants were once more put to the sword and the town was pillaged. From this disaster the inhabitants recovered so far as to be able to give an effectual check to an invasion of the Goths in the reign of Claudius II., and the fortifications were strengthened during the civil wars which followed the abdication of Diocletian. Diocletian had resolved to transfer his capital to Nicomedia; but Constantine, struck with the advantages which the situation of Byzantium presented, resolved to build a new city there on the site of the old and transfer the seat of government to it (A.D. 330). (See CONSTANTINOPLE.)

**C** the third letter of the alphabet, corresponds to Semitic **ג** *gimel*, and Greek **Γ**. *gamma*. Greek forms were **Γ**, **Ϛ**, **Λ**, **Ϝ**. From the last derived the round form **Ϝ**, which occurs at Corinth and in the Chalcidic alphabet. Both **Ϝ** and **Ϝ** are found in the early Latin alphabet, as well as in Etruscan. The rounded form survived and became general, and the shape of the letter has since altered but little. In certain mediaeval forms of writing the minuscule letter tended to become pointed, e.g., **Ϛ**. Roman cursive forms are shown in the illustration below.

The sound represented by the letter in Semitic and in Greek was the voiced velar stop, represented in English by the "hard" **g**. In the Latin alphabet it came to represent the unvoiced velar stop, and was for some time, it appears, used for both the voiced and unvoiced sounds. This change must in all probability be due to Etruscan influence, for the voiced stops

| NAME OF FORM                | APPROXIMATE DATE                  | FORM OF LETTER |

DEVELOPMENT OF THE LETTER C FROM ITS EARLIEST TO ITS PRESENT FORM

apparently did not exist in the Etruscan language, with the result that the third letter of the alphabet, as taken over by the Etruscans in Asia Minor from a source which was also that of the Greek

alphabet, was used for the corresponding unvoiced sound. An early Latin inscription exists in which the word **RECEI** occurs, the letter being still employed to represent the voiced sound. Finally a new symbol **G** was used for the voiced sound, and **C** displaced **K** as the representative of the unvoiced stop.

In modern English the letter represents two separate sounds (1) the unvoiced velar stop as in the Latin alphabet, and (2) the unvoiced sibilant, identical with the sound represented by **s** in certain positions. The letter represents the sibilant when preceding either of the front vowels, **e** and **i** (e.g., in *receive*, *cider*); in all other cases (except before **h**) the velar (e.g., *call*, *come*, *clear*, *crumb*, *epic*). This is due to the palatalization of the velar in early mediaeval times before the front vowel, the stages of sound-change being **k** > **kj** > **tʃ** > **ts** > **s**. The letter **c** was applied by French orthographers in the 12th century to represent the sound **ts** in English, and this sound developed into the simpler sibilant **s**. Gradually the use of the letter **c** to represent the velar before front vowels (for example in the Middle English *cyng*) gave way to that of **k**, ambiguity being thus as far as possible avoided. **C** takes the place of **s** in words such as *mice*, *advice*, in which **s** would represent a 'voiced' sibilant (identical with the sound of **z**), and in words such as *practice* merely as a means of grammatical distinction.

Before **k** the letter is often redundant (e.g., in *thick*, *clock*, etc.). The combination **ch** represents a double unvoiced palatal (**tʃ**), as in *church*.

In music, **C** is the name of the third note of the musical alphabet, this note being at the same time one which has always occupied a peculiarly distinctive position, in that it is the key note of what used to be called, from the fact that it contains no accidentals, the "natural scale." Thus on the pianoforte it consists entirely of white notes and hence has come to be regarded as the simplest and most fundamental of all keys. **C** is further one of the three notes (**F** and **G** being the others) which have served for centuries, in conjunction with the appropriate signs, to indicate the clefs. (See **CLEF**.)

**CAB.** A colloquial abbreviation of the French *cabriolet*, originally a passenger-vehicle drawn by two or four horses. It was introduced into London from Paris in 1820. London not only turned "cabriolet" into "cab" (a word which became officially enshrined in an act of Parliament, the London Cab act of 1896) but further invented for it the terms "four-wheeler" and "growler." The fashionable horse-cab, however, was the "hansom," a one-horsed form, with two big wheels, of very uncertain equilibrium and dangerous character, in which the driver was perched in a dicky placed high up at the back of the vehicle and took his instructions through a small trap-door in the roof. It was difficult to enter a hansom without soiling one's clothes. As originally invented by J. A. Hansom in 1834, however, it was a comparatively safe vehicle, with the driver placed at the side. Horse-cabs quickly became obsolete in great cities with the appearance of the taxicab, a licensed motor vehicle fitted with a taximeter. Cabs plying publicly for hire are in all countries subject to local licensing laws and official fare determinations which are constantly under review. (See **TAXIMETER**.)

**CABAL**, a private organization or party engaged in secret intrigues, and applied also to the intrigues themselves (through the Fr. *cabale*, from the Cabbala or Kabbalah, the theosophical interpretation of the Hebrew scriptures). In England the word had been jealously used throughout the 17th century, with the alternative *junto* or *cabinet* (*q.v.*), to describe any secret and extra-legal council of the king, more particularly the foreign committee of the Privy Council. The invidious meaning attached to the term was stereotyped by the coincidence that the initial letters of the names of Charles II.'s ministers, Clifford, Arlington, Buckingham, Ashley and Lauderdale, spelled cabal.

**CABALETTA**, a musical term which is really a modified form of *cavatina* (It.), and therefore means strictly a small *cavatina* (*q.v.*), but in practice it has come to be applied to the quick concluding section or final phrases of a vocal number.

**CABALLERO, FERNÁN** (1796–1877), the pseudonym adopted by the Spanish novelist Cecilia Francisca Josefa Böhl de Faber. Born at Morges in Switzerland, she was the daughter of Johan Nikolas Böhl von Faber, a Hamburg merchant, known to the students of Spanish literature as the editor of the *Floresta de rimas antiguas castellanas* (1821–25), and the *Teatro español anterior á Lope de Vega* (1832). Educated principally at Hamburg, she visited Spain in 1815, married and settled there, and in 1849 became famous as the author of *La Gaviota*. She had already published in German an anonymous romance, *Sola* (1840), and curiously enough the original draft of *La Gaviota* was written in French. This novel was translated into most European languages, and, though it scarcely seems to deserve the intense enthusiasm which it excited, it is the best of its author's works, with the possible exception of *La Familia de Alvareda* (which was written, first of all, in German). Less successful attempts are *Lady Virginia* and *Clemencia*; but the short stories entitled *Cuadros de Costumbres* (1862) are interesting in matter and form, and *Una en otra* and *Elia ó la España treinta años ha* are excellent specimens of picturesque narration. It would be difficult to maintain that Fernán Caballero was a great literary artist, but it is certain that she was a born teller of stories and that she has a graceful style very suitable to her purpose. She came into Spain at a most happy moment, before the new order had perceptibly disturbed the old, and she brought to bear not alone a fine natural gift of observation, but a freshness of vision, undulled by long familiarity. She combined the advantages of being both a foreigner and a native. In later publications she insisted too emphatically upon the moral lesson, and lost much of her primitive simplicity and charm; but though she occasionally idealized circumstances, she was conscientious in choosing for her themes subjects which had occurred in her own experience. Hence she may be regarded as a pioneer in the realistic field, and this historical fact adds to her positive importance.

See M. A. Morel-Fatio, *Études sur l'Espagne* (1904), iii., pp. 279–370. (J.F.-K.)

**CABANATUAN**, a municipality (with administration centre and eight *barrios* or districts) and capital of the province of Nueva Ecija, Luzon, Philippine Islands; and one of the chief commercial centres of the province. Pop. (1918) 15,286, of whom 14 were whites. It is well situated on the Manila-Dagupan railway and on the Pampanga river and has excellent roads. In 1918 it had 33 household industry establishments, with output valued at 12,600 pesos; four rice mills, with by-products valued at 199,000 pesos; and 17 manufacturing establishments, with output valued at 94,500 pesos. It has ten schools (nine public). Pampango and other languages are spoken.

**CABANEL, ALEXANDRE** (1823–1889), French painter, was born at Montpellier on Sept. 28 1823, and died in Paris on Jan. 23 1889. He studied under Picot, and gained the Prix de Rome in 1845. As director of the École des Beaux-Arts under Napoleon III. he exercised some influence. His subject pictures were enormously popular in their day—an example is the "Birth of Venus" in the Luxembourg—but he is now remembered only for some of his portraits.

**CABANIS, PIERRE JEAN GEORGE** (1757–1808), French physiologist, was born at Cosnac (Corrèze), and was the

son of Jean Baptiste Cabanis (1723–86), a lawyer and agronomist. In 1789 his *Observations sur les hôpitaux* procured him an appointment as administrator of hospitals in Paris, and in 1795 he became professor of hygiene at the medical school of Paris, a post which he exchanged for the chair of legal medicine and the history of medicine in 1799. He acted as physician to Mirabeau, and wrote the four papers on public education which were found among the papers of Mirabeau at his death. Cabanis was a member of the Council of Five Hundred and then of the conservative Senate, but his political career ended with the triumph of Napoleon.

His principal work, *Rapports du physique et du moral de l'homme*, consists in part of memoirs, read in 1796 and 1797 to the Institute, and is a sketch of physiological psychology. He adopted at first a purely materialistic view, but went over to the vitalistic school of G. E. Stahl, and in the posthumous work, *Lettre sur les causes premières* (1824), the consequences of this opinion became clear.

**CABARRUS, FRANÇOIS** (1752–1810), French-Spanish financier, was born at Bayonne in 1752 and died at Seville on April 27, 1810. He settled in Madrid as a soap manufacturer and presently became one of the financial advisers of Charles III. He devoted his considerable financial talents to the organization of a bank, to the formation of a company to trade with the Philippine Islands, and to a reformation of the currency and taxation. But these financial measures were hindered by the death of Charles III. In 1788. There was no place in the reactionary Government of Charles IV. for the group of reformers. Cabarrus spent two years in prison on a charge of embezzlement. He was presently restored to some degree of favour and was nominated Spanish ambassador to Paris, but the Directory raised objection to his appointment on the grounds of his French birth. Cabarrus took no part in the intrigues by which Charles IV. was compelled to abdicate and his son deprived of the succession in favour of Joseph Bonaparte, but he became minister of finance under Joseph's Government and held that post until his death. His daughter, Thérèse, became well known as Madame Tallien, afterwards princess of Chimay.

**CABASILAS, NICOLAUS** (d. 1371), Byzantine mystic and theologian. In 1355 he succeeded his uncle Nilus Cabasilas, like himself, a determined opponent of the union of the Greek and Latin churches, as archbishop of Thessalonica. In the Hesychast controversy he took the side of the monks of Athos but refused to agree to the theory of the uncreated light. His chief work is his *Περὶ τῆς ἐν Χριστῷ ζωῆς* (*ed.pr.* of the Greek text with copious introduction, by W. Gass, 1849; new ed. by M. Heinze, 1899), in which he declares that union with Christ is effected by three great mysteries of baptism, confirmation, and the eucharist. He also wrote homilies on various subjects and a speech against usurers, printed in Migne, *Patrol. Graeca*.

See C. Krumbacher, *Geschichte der byzantinischen Literatur* (1897), and Herzog-Hauck, *Realencyklopädie*.

**CABATUAN**, a municipality (with administration centre and 56 *barrios* or districts) of the province of Iloilo, Panay, Philippine Islands, on a branch of the Suague river, 15 m. N. of Iloilo, the capital, and a few miles from the railway. Pop. (1918) 14,816, of whom none were white. The climate is healthful and the surrounding fertile country produces rice, corn, tobacco, sugar, coffee and many fruits. In 1918 it had 608 household industry establishments with an output valued at 126,400 pesos, and 9 sugar-mills. Of the 26 schools, 11 were public. The language spoken is a dialect of Bisayan.

**CABBAGE**, a table vegetable and fodder plant whose various forms are supposed to have been developed by long cultivation from the wild or sea cabbage (*Brassica oleracea*), a plant found near the sea coast of various parts of England and continental Europe. The cultivated varieties, however, have departed widely from the original type, and they present marked and striking dissimilarities among themselves. The wild cabbage is a comparatively insignificant plant, growing 1 to 2 ft. high, in appearance similar to charlock (*Sinapis alba*) but having smooth leaves. The wild plant has fleshy, shining, waved and lobed leaves (the uppermost being undivided but toothed), large yellow flowers, elongated

seed-pod, and seeds with conduplicate cotyledons. Notwithstanding the fact that the cultivated forms differ in habit so widely, the flower, seed-pods and seeds present no appreciable difference.

John Lindley proposed the following classification for the various forms: (1) All the leaf-buds active and open, as in wild cabbage and kail or greens; (2) all the leaf-buds active, but forming heads, as in Brussels sprouts; (3) terminal leaf-bud alone active, forming a head, as in common cabbage, savoy, etc.; (4) terminal leaf-bud alone active and open, with most of the flowers abortive and succulent, as in cauliflower and broccoli; (5) all the leaf-buds active and open, with most of the flowers abortive and succulent, as in sprouting broccoli. The last variety bears the same relation to common broccoli as Brussels sprouts do to the common cabbage. Of all these forms there are numerous gardeners' varieties.

Under Lindley's first class, common or Scotch kail or borecole (*Brassica oleracea*, form *acephala*), includes several varieties which are amongst the hardiest of our esculents, and yield winter greens. They require well-enriched soil, and sufficient space for full exposure to air; and they should also be sown early, so as to be well established and hardened before winter. The plants send up a stout central stem, growing upright to a height of about 2ft., with close-set, large, thick, plain leaves of a light red or purplish hue. The lower leaves are stripped off as the plants grow up, and used for the preparation of broth or "Scotch kail," a dish at one time in great repute in north-eastern Scotland. A remarkable variety of open-leaved cabbage is cultivated in the Channel Islands under the name of the Jersey or branching cabbage.

It commonly grows to a height of 8ft., but it has been known to attain double that height. It throws out branches from the central stem, which is sufficiently firm and woody to be fashioned into walking-sticks; and the stems are used by the islanders as rafters for bearing the thatch on their cottage-roofs. Several varieties are cultivated as ornamental plants on account of their beautifully coloured, frizzed and lacinated leaves.

Brussels sprouts (*Brassica oleracea*, form *gemmifera*) are miniature cabbage-heads, about an inch in diameter, which form in the axils of the leaves.

The third class is chiefly represented by the common or drum-head cabbages (*Brassica oleracea*, form *capitata*), the varieties of which are distinguished by size, form and colour. In Germany it is converted into *Sauerkraut* by placing in a tub alternate layers of salt and cabbage. An acid fermentation sets in, which after a few days is complete, when the vessel is tightly covered over and the product kept for use with animal food.

The savoy (*B. oleracea*, form *subanda*) is a hardy green variety, characterized by its wrinkled leaves.

Cabbages contain a very small percentage of nitrogenous compounds as compared with most other articles of food. Their food-

value apart from their salt and vitamin content is therefore small. The red cabbage (*Brassica oleracea*, form *capitata rubra*), of which the Dutch red is the most commonly grown, is much used for pickling. The dwarf red and Utrecht red are smaller.

Cauliflower, the chief representative of class 4, consists of the inflorescence of the plant modified to form a compact succulent white mass or head. The cauliflower (*Brassica oleracea*, form *botrytis cauliflora*) is said to have been introduced from Cyprus. It is one of the most delicately flavoured of vegetables, the dense cluster formed by its incipient succulent flower-buds being the edible portion.

Broccoli is merely a variety of cauliflower, differing in the form and colour of its inflorescence and its hardness. The broccoli (*Brassica oleracea*, form *botrytis cauliflora*) succeeds best in loamy soil, somewhat firm in texture.

Broccoli sprouts, the representative of the fifth class, consist of flowering sprouts springing from the axils of the leaves. The purple-leaved variety is very hardy and much-esteemed.

Kohl-rabi (*Brassica oleracea*, form *gongylodes* or *caulorapa*) is a peculiar variety in which the stem, just above the ground, swells into a fleshy turnip-like mass. It is much cultivated in certain districts as a food for stock, for which purpose the drumhead cabbage and the thousand-headed kail are also largely used. Kohl-rabi is exceedingly hardy, withstanding both severe frosts and drought. It is not much grown in English gardens.

Several species of palm, from the fact of yielding large sapid central buds which are cooked as vegetables, are known as cabbage-palms. The principal of these is *Oreodoxa oleracea*, but other species such as the cocopalms and the royal palm (*Oreodoxa regia*) yield similar edible leaf-buds.

For further details see J. Percival, *Agricultural Botany* (London, 1926); W. W. Robbins, *Botany of Crop Plants* (Philadelphia, 1926).

**CABEIRI**, an important group of deities, perhaps of Phrygian origin, worshipped over a large part of Asia Minor, on the islands near by, particularly Lemnos and Samothrace, and in Macedonia and northern and central Greece, especially Boeotia. (*κάβειροι*, in Boeotian *κάβιροι*, is commonly identified with Phoen. *Qabirim*, "mighty ones," cf. their common Gr. and Lat. appellation "great gods"; but this is seriously doubted by several scholars, who take it to be an Anatolian word of unknown meaning). They were underworld powers of fertility, perhaps originally indefinite in number; in classical times there appear to have been two male deities, Axiocersus and his son and attendant Cadmilus or Casmilus, and a less important female pair, Axierus and Axiocersa (meaning of names unknown). These were variously identified by the Greeks with gods of their own pantheon (Hephaestus, Dionysus, Demeter and Kore, the Dioscuri, etc.). The cult included worship of the power of fertility, symbolized by the male organ of generation; there were also, as usual in mysteries such as these were, rites of purification, which seem ultimately at least to have included insistence on moral purity; also initiation, presumably

into the favour and intimacy of the gods. An obscure legend preserved by ecclesiastical writers says that there were three male Cabeiri, of whom two killed and beheaded the third.

They are often called the Samothracian gods, from the fame of their cult at Samothrace. There, as early as the 5th century B.C., their mysteries attracted great attention, and initiation was looked upon as a general safeguard against all misfortune, particularly against shipwreck. But it was in the period after the death of Alexander the Great that their cult reached its height, and initiation was sought, not only by large numbers of pilgrims, but by persons of distinction. The island possessed the right of asylum or sanctuary, for which purpose it was used by Arsinoë, wife and sister of Ptolemy Ceraunus, who, to show her gratitude, afterwards caused a monument to be erected there, the ruins of which were explored in 1874 by an Austrian archaeological expedition. In 1888 interesting details as to the Boeotian cult of the Cabeiri were obtained by the excavations of their temple in the neighbourhood of Thebes, conducted by the German archaeological institute. The two male deities worshipped were Cabeirus and a boy (probably Axiocersus and Cadmilus). The Cabeirus resembles Dionysus. The Cabeiri were held in even greater esteem by the Romans, who, claiming Trojan descent, identified them with the *Penates publici* (see *PENATES*).

**CABELL, JAMES BRANCH** (1879– ), American author, was born at Richmond (Va.), April 14 1879. He was instructor in French and Greek at William and Mary College in 1896–97, graduating with the degree of B.A. in 1898. He began newspaper work at Richmond and was on the staff of the *New York Herald* in 1899–1901. He later engaged in coal mining in West Virginia, contributed short stories to magazines, and interested himself in genealogical and historical research. His work has a distinct individuality, presenting a central conception of human life fitted chiefly to an imaginary mediaeval country, Poictesme, in which the principal actions take place, its inhabitants being ancestors of the other characters in his novels.

His various volumes fit into what he called the "Biography" in approximately the following order: *Beyond Life* (1919); *Figures of Earth* (1921); *The Silver Stallion* (1926); *Domnei* (1920); revised edition of *The Soul of Melicent* (1913); *Chivalry* (1909); *Jurgen* (1919); *The Line of Love* (1905); *The High Place* (1923); *Gallantry* (1907); *The Certain Hour* (1916); *The Cords of Vanity* (1909); *From the Hidden Way* (1916), verse; *The Rivet in Grandfather's Neck* (1915); *The Eagle's Shadow* (1904); *The Cream of the Jest* (1917); *Straws and Prayer-Books* (1924); *Something About Eve* (1929); and *The Way of Ecce* (1929). An ironic romancer whose professed object was "to write perfectly of beautiful happenings," Cabell had to wait for the suppression of *Jurgen* to win him a wide reputation, although he early secured a small, devoted following.

See Carl Van Doren, *James Branch Cabell* (1925), and Guy Holt, *A Bibliography of the Writings of James Branch Cabell* (1924), which contains valuable references.

**CABER TOSSING**, a Scottish athletic game which consists in throwing a section of a trunk of a tree, called the "caber" (Gaelic *cabar*, a pole or beam), in such a manner that it shall turn over in the air and fall on the ground with its small end point-

FROM ROBBINS, "BOTANY OF CROP PLANTS"

A. The entire plant  
B. A portion of the "head" consisting of the fleshy stalks of inflorescence with small flowers and buds (enlarged)

ing in the direction directly opposite to the "tosser." Tossing the caber is usually considered to be a distinctly Scottish sport, although "casting the bar," an exercise evidently similar in character, was popular in England in the 16th century but afterwards died out. The caber is the heavy trunk of a tree from 16 to 20 ft. long. It is often brought upon the field heavier than can be thrown and then cut to suit the contestants, although sometimes cabers of different sizes are kept, each contestant taking his choice. The toss is made after a run, the caber being set up perpendicularly with the heavy end up by assistants on the spot indicated by the tosser, who sets one foot against it, grasps it with both hands, and, as soon as he feels it properly balanced, gives the word to the assistants to let go their hold. He then raises the caber and gets both hands underneath the lower end. "A practised hand, having freed the caber from the ground, and got his hands underneath the end, raises it till the lower end is nearly on a level with his elbows, then advances for several yards, gradually increasing his speed till he is sometimes at a smart run before he gives the toss. Just before doing this he allows the caber to leave his shoulder, and as the heavy top end begins to fall forward, he throws the end he has in his hands upwards with all his strength, and, if successful, after the heavy end strikes the ground the small end continues its upward motion till perpendicular, when it falls forward, and the caber lies in a straight line with the tosser" (W. M. Smith). The winner is he who tosses with the best and easiest style, according to old Highland traditions, and whose caber falls straightest in a direct line from him. The champion caber tossers of Scotland were E. W. Currie and Wm. Perrie and Dr. C. Ross; their performances included tosses of 40 to 42 ft., made during 1880–95. In America a style called the Scottish-American prevails at Caledonian games. In this the object is distance alone, the same caber being used by all contestants and the toss being measured from the tosser's foot to the spot where the small end strikes the ground. This style is repudiated in Scotland. Donald Dinnie, born in 1837 and still a champion in 1890, was the best tosser of modern times.

Caber tossing is usually held annually under the auspices of the New York Caledonian Club and included in the programme of track and field sports, although the game is not as popular in America as it used to be. James Cumming, born in Scotland, is the record-holder in America.

See W. M. Smith, *Athletics and Athletic Sports in Scotland* (1891).

**CABET, ETIENNE** (1788–1856), French Socialist, was born at Dijon in 1788, the son of a cooper. He practised at the bar in Dijon until 1820, and then settled in Paris, where he became director of the "Vente Suprême," the local association of Carbonari. After the revolution of 1830, he was made procureur-général in Corsica; but was dismissed for an attack on the Government in his *Histoire de la révolution de 1830*. Elected for Dijon to the chamber of deputies, he was prosecuted for his bitter criticism of the Government, and went into exile in England in 1834, where he became an ardent disciple of Robert Owen. On the amnesty of 1839 he returned to France, and wrote his *Histoire de la Révolution française* (1840), and published his *Voyage en Icarie* (1840), which he had written in London after reading the *Utopia* of Sir Thomas More. The *Voyage en Icarie* contains his theories on progressive taxation, on compulsion to work, old age pensions, and the division of the products of industry. Like Owen, he sought to realize his ideas in practice. By negotiations in England favoured by Owen, he bought a tract of land on the Red river, Texas, and drew up a scheme for the intended colony, community of property being the distinctive principle of the society. In 1848 an expedition of 1,500 "Icarians" sailed to America; but unexpected difficulties arose and the complaints of the disenchanting settlers soon reached Europe. Cabet went out in 1849, but on his arrival, finding that the Mormons had been expelled from their city Nauvoo, in Illinois, he transferred his settlement there. With the exception of a journey to France, where he returned to defend himself successfully before the tribunals he remained at Nauvoo, the dictator of his little society. After a time dissensions arose and Cabet, with some 200 of the community left Nauvoo to form a new settlement. He died at

St. Louis (Mo.), on Nov. 8, 1856. He placed his Socialism on a religious basis, and wrote a book entitled *Le vrai christianisme de Jésus Christ* (1846).

See Nordhoff, *Communist Societies of the United States* (1875); Félix Bonnaud, *Cabet et son œuvre, appel à tous les socialistes* (1900); J. Prudhommeaux, *Icaria and its Founder, Étienne Cabet* (1907).

**CABIN**, originally a small, roughly built hut or shelter; it is particularly applied to the thatched mud cottages of the negroes of the southern states of the United States of America, or of the poverty-stricken peasantry of Ireland or the crofter districts of Scotland. In a special sense it is used of the small rooms or compartments on board a vessel used for sleeping, eating or other accommodation.

**CABINDA:** see ANGOLA.

**CABINET, THE.** The word "cabinet," like most British constitutional terms, is of foreign extraction, and originally signified a small room (compare the 18th century use of the word "closet"). Hence cabinet counsel came to mean secret counsel and cabinet council the body of persons that gave such counsel. Thus Bacon, in a famous passage, discussing the disadvantages of large councils, writes that "the doctrine of Italy and practice of France, in some kings' times, hath introduced cabinet councils, a remedy worse than the disease, . . . that is . . . councils of gracious persons recommended chiefly by flattery and affection."

Organically, the cabinet derived from the Privy Council. Even in Tudor times, owing to the large number of counsellors and to facilitate the subdivision of labour, there were appointed many standing and temporary *ad hoc* committees of the council; and the practice was continued under the Stuarts. James I., it is true, preferred the advice of individual favourites, and the same may be said of Charles I. at the beginning of his reign. But, after the murder of Buckingham, one of these committees, usually called the foreign committee, gradually developed outstanding importance. On it sat the king's most intimate advisers and debated the most serious affairs of State, as well domestic as foreign, decisions being frequently taken in this committee before the subject of the decision had even been broached before the Privy Council, the functions of which were thus to a large extent usurped. Contemporary opinion strongly disapproved of such procedure; the Grand Remonstrance, presented to the king on Dec. 1, 1641, refers to the grievance in clause 59, and the Commons returned to the charge more explicitly in an address of Feb. 1642. "Reproachfully" and "enviously," to use Clarendon's expressions, such committees were called "junctos," "cabals" or "cabinet councils."

**The Committee for Foreign Affairs.**—At the Restoration, under the auspices of Clarendon, who had survived the deluge, the practice was revived with "that secret committee with the chancellor, which under the notion of foreign affairs, was appointed by the king to consult all his affairs before they came to public debate." On Clarendon's fall, the precedent was followed by a standing committee of the Privy Council, called the committee for foreign affairs, which committee, owing to the coincidence of the initial letters of the names of some of the members (Clifford, Ashley, Buckingham, Arlington and Lauderdale), has passed into history as *the Cabal*, and, even under Danby, although opposition forced the king to greater circumspection, similar caballing in committee unofficially went on.

The position then up to 1679, when, owing to the revelations of Titus Oates and the consequent triumph of the country party, Charles was obliged to submit to conciliar reform, was as follows. There existed, first, a privy council of some 47 members, among whom the highest officials formed the effective nucleus; secondly, many standing and temporary *ad hoc* committees of the Privy Council, limited in membership, on all of which committees the greatest officials sat *ex officio* (from time to time certain other individuals were by royal favour appointed to all committees); and, thirdly, a committee for foreign affairs, sometimes, but not always, a properly constituted formal standing committee of council, variously termed by contemporaries a cabal, juncto or cabinet, and mainly, though not exclusively, composed of persons holding high political office, on which committee domestic, as well as foreign, affairs were debated and settled, formal decision

only—and sometimes not even that—being left to the Privy Council.

**The Committee of Intelligence.**—It was the object of what is usually known as Temple's scheme to reduce the size of the Privy Council and to include in its membership representatives of every shade of parliamentary opinion. The new council thus contained enemies, as well as friends, of the king, as did also its committees, the most important of which was "a Committee of Intelligence for the opening and considering all Advices as well foreign as domestic." Here, at last, was an official committee of council, legally empowered to undertake all those labours (except the short-circuiting of the Privy Council) hitherto extra-legally performed by the foreign committee. Since, however, it was composed of enemies as well as friends, Charles, in spite of recent promises to cease caballing, began at once to consult informally in his cabinet with those members of the committee who were of the court party, occasionally summoning to such discussions other individual friends, who were not members of the committee at all. There were thus a formal committee of intelligence, composed of friends and enemies, and an informal cabinet, composed of the friendly members of the committee reinforced by a friend or two from without. It was not long before the Opposition representatives on council and committees came to realize that their membership was a farce, since Charles did not take them into his confidence. Gradually they forbore attendance. By Feb. 1681 they had ceased to attend. The vacancies thus occasioned on the committee of intelligence left room for the inclusion of those members of the cabinet who had not hitherto been members of the committee. On the other hand, with the defection of the opposition members of the Privy Council, Temple's scheme might be said to have broken down. If the experiment had failed, if the Privy Council had reverted to its former constitution, what authority for its continued existence had the committee of intelligence, which owed its origin to that experiment? This doubt may account for the fact that, with the disappearance of the country party members from the council, the committee of intelligence ceases to call itself by that name, ceases in fact to exist, and is replaced, or rather continued, under the older and more familiar title of "the committee for foreign affairs." A year or so later, dropping all prefix and suffix, it becomes known simply as "the committee," partly, no doubt, because, being by far the most important committee of council, it ran no danger of confusion with the others, and partly, perhaps, because all the other committees of the Privy Council were at this time in process of being opened up to all members of the council, and the committee was thus the only one to retain limited membership.

**Routine.**—The routine of "committee" and "cabinet" survived the Catholic caballing of James II. and the idiosyncrasies of William III., who understood ministers but not ministries, to become under Anne the accepted, if still unpopular, machinery of executive government. The committee, meeting as often as necessary throughout the week in the office of the senior secretary of State at the Cockpit in Whitehall, deliberated upon all business of government and prepared it for the sovereign. Once a week (unless emergency dictated an extra meeting), the lords of the committee attended the sovereign in her cabinet, where the business prepared in committee would be brought to the royal notice and final decisions would be taken. By this time, only formal business would be transacted at meetings of the Privy Council, discussion and debate there being prohibited, although it might still be a wise precaution, in view of the possibility of later enquiries, for ministers to bring their most controversial measures before the board for formal ratification. As long as the sovereign continued to attend the meetings of the cabinet, the system of separate meetings of the committee at the Cockpit and of the cabinet in the royal palace possessed certain obvious advantages. But when George I., who had no English, from 1717 onwards ceased to attend, those advantages disappeared. Less and less frequently in the succeeding years did the lords of the committee come to the palace to wait upon a king who never turned up. Their business, whether preparative or decisive, could now equally well be dealt with at the Cockpit. Nor was there any longer need for two

titles whereby to describe what was now one and the same body. The designation, "the committee," is dropped. It is as "the cabinet," since that had been the title of the decisive body, that the executive is in future known; and, gradually, as its presiding officer, to take the place of an absentee sovereign, there evolves a prime minister.

**Personnel.**—Even in the early 17th century, before the foreign committee had begun to usurp the functions of the Privy Council, the main work of the latter was done by a small number of the most important officials, who alone were constant in their attendance. These included the archbishop of Canterbury, the lord chancellor, the lord treasurer, the lord president (when there was one), the lord privy seal, the two secretaries, and a number of household officials (all the royal ministers were, of course, originally household servants), of whom the most important were the lord steward and the lord chamberlain. These again formed the nucleus of the committees of council, and, although it would not be true to say that the foreign committee normally contained these officials, or indeed the majority of them, yet it is a fact that, in proportion as the foreign committee and its descendants developed into the recognized executive of the nation, so did it tend to be composed more and more exclusively of the greatest political officials, for the simple reason that their collaboration, and their collaboration alone, was necessary to the conduct of government. When the cabinet and committee system emerges towards the close of Charles II.'s reign, these bodies possess only from six to seven members; in William III.'s reign there are sometimes nine; under Anne, ten or 12. Now we cannot call even a dozen an excessive total for the great officers of State or for the proper conduct of business. But later, under the Hanoverians, there was a constant tendency, difficult to check, towards an increase of membership by the inclusion of individuals, either (1) holding offices which, although of no great political weight, had occasionally, in the past, carried cabinet rank, or (2) possessing great political connections and borough interests which it might be necessary to placate, or (3) personally dear to the sovereign. Thus by 1740 the cabinet had from 16 to 17 members, by 1745 20, and in 1761, when the high water mark of 21 was reached, we read that cabinet councillor is "a rank that will soon become indistinct from that of privy councillor by growing as numerous."

**"The Inner Cabinet."**—Not unnaturally the more "efficient" members had begun to concert business privately. As long as the sovereign continued to preside at cabinet meetings, such informal gatherings, of course, would not be tolerated, nor indeed for a decade after his abstention did the cabinet swell to such a size as would necessitate or justify such a proceeding. It is during Walpole's long administration that the practice originates and develops into a regular habit. From 1727 to 1729 we hear of "select lords who are usually consulted in foreign affairs"; by 1738 this reference of foreign negotiations to a select few has become "the usual practice." From 1735 we begin to hear of "private meetings at Sir Robert Walpole's." All this is informal. But from 1739–1741, as a result of war, of the absence of the king abroad and of the greater need in consequence both of secrecy and of formality of communication with the sovereign, there emerges a recognized group of five officials, the first lord of the Treasury (who was also chancellor of the exchequer), the lord chancellor, the lord president and the two secretaries of State, virtually in sole charge of affairs. This group deals with the most important business of every kind. It meets frequently, as occasion demands. It keeps minutes. It communicates directly with the sovereign and not via the cabinet. It meets at Walpole's house, whereas the cabinet sits at Whitehall. Its membership is definitely approved by the king, and the responsibility of members of this inner ring is recognized as greater than that of other cabinet ministers. But it could not actually supplant the cabinet, until it had expanded to include all the really efficient members of the cabinet. This was effected in the course of the next quarter of a century. In 1752 the first lord of the admiralty was added to the inner group, in 1755 the lord privy seal, and in 1766 the chancellor of the exchequer, an office that since the Treasury had been put into commission, had usually been held by the first lord

of the Treasury, was admitted on an independent footing. By that date the entire cabinet was only summoned on formal occasions for the transaction of formal business; by 1775 it had become "a nominal cabinet"; and by 1783, when the younger Pitt formed his administration, it had to all intents and purposes ceased to exist.

Until the middle of the 19th century, the small, efficient cabinet suffered practically no greater increase in membership than can be accounted for by the creation of additional secretaries of State. From then on, however, the total rose rapidly. In 1867 it stood at 16; in 1900 at 20; during the World War it reached 23; and since then all efforts to keep it below a score have failed. This increase is due, not, as in the 18th century, to the accretion of "inefficient" members, but to the creation of new and important governmental departments, each with a responsible ministerial chief, to administer the ever-swelling bulk of social legislation. The concentration of the control of policy into the hands of a small, inner group—a proposal advocated by many as the best solution to the problem of an overgrown executive—is not, therefore, so easy a matter as it was two centuries ago. Nevertheless, something of the sort did develop during the war, although again in contradistinction to the inner cabinet of the 18th century the war cabinet was at times composed, not of the greatest office-holders, but on the contrary to a large extent of ministers without portfolio, deliberately so chosen, in order that, free from departmental duties, they might devote the whole of their time to general policy. After the World War there were further rumours of an informal inner ring of ministers, and one writer on the subject (Carthill, *Rods and Axes*, 1928) declares that: "A practice has sprung up of constituting an inner cabinet within the cabinet. This is not a true managing committee, nor is it a true regulator; it is an informal council of close political friends of the premier, and its existence is not formally recognized."

**Principles of Cabinet Government.**—Functionally, the cabinet may be described as a committee of privy councillors, with seats in parliament, united by political principle and professing unanimity in public, under the leadership of the acknowledged head of the party commanding a majority in the House of Commons, by whom, with the sovereign's assent, they have been appointed to the control of the principal government departments, to act through him as the sovereign's sole advisers, and to be severally and jointly responsible to the sovereign, the prime minister, parliament and the people, for their individual and collective actions, so long as they are supported by a majority of the House of Commons. The principles of cabinet government set forth in this definition have achieved recognition as the result of nearly three centuries of ministerial and party conflict. There is, of course, no law compelling ministers to be members of parliament. On the contrary, for two centuries, through fear, at first of the influence of the Crown, and later of ministerial corruption, repeated efforts were made to exclude all placemen from the House of Commons. It was only when with the carriage of "economical" reform by the Rockingham administration of 1782 and with the passage of the Reform bill of 1832 the dangers of a bought majority had been removed, that the advantages of the presence of the executive in the legislature were fully understood. During the 18th century, the majority of cabinet ministers were peers; in the 19th and 20th centuries, commoners; but each of the chief departments has usually a ministerial representative in either house. That ministers should be united by political principle was a doctrine first, and prematurely, enforced on his cabinet by Walpole. Later, it was enunciated as the official Whig doctrine, in opposition to the personal government of George III. and Chatham's dogma of "men not measures," by Burke in his *Thoughts on the Causes of the Present Discontents* (1770), and, with the fall of personal government, may be said to have triumphed, although even to this day coalition governments occasionally violate the principle. Unanimity in public is an obvious corollary. The principle is summed up in Lord Melbourne's dictum "I don't care what we say, but we'd better all say the same thing." Since then independent action, contrary to the policy of the Government, has always been followed by the resignation of the individual

concerned, for instance Lord Palmerston's congratulation of Napoleon III. on the *coup d'état* of 1851 and E. Montagu's publication of a protest of the Indian Government against the treaty with Turkey in 1922.

The principles governing the relations between the cabinet and its chief belong to the story of the evolution of the office of prime minister (*q.v.*); that the latter should be the head of the party commanding a majority in the lower house is the natural outcome of the Reform bills of the 19th century, although, even to this day, if there are more than two parties in existence, none of which commands an absolute majority, it is possible for the head of a minority to be in power, *e.g.*, J. Ramsay MacDonald and the Labour Government of 1924. The sovereign's assent to ministerial appointments made by the prime minister is the residue of the former unfettered powers of the council to appoint what ministers it pleased; but the statement that members of the cabinet are in control of the principal government departments needs some qualification. In the 18th century there were several instances of cabinet ministers without portfolio (Pulteney in 1742, Hardwicke in 1757, Conway in 1770 and Camden in 1798); during the World War, at one period, of a war cabinet of seven, four ministers held no departmental office; and, among the offices which habitually carry cabinet rank, there are several, as, for instance, the lord president and the lord privy seal, which nowadays involve no departmental duties. The doctrine that the king should be advised solely by his ministers was slow in achieving recognition. It may properly be said to have done so during the younger Pitt's administration (1783-1801). As regards the minor household posts, the controversy revived for a moment with the Bedchamber Question of 1839, but was finally settled with the queen's surrender on Peel's assumption of office in 1841.

The cabinet it has been said, is responsible to the sovereign, to the prime minister, to parliament and to the people; but the nature of the responsibility varies in each case. The sovereign must be kept fully informed, his advice taken and his consent obtained. Between Crown and cabinet the prime minister ordinarily acts as intermediary, but it is always possible for the sovereign to reprimand a minister who has failed in respect or duty, as did Queen Victoria in her famous memorandum to Lord Palmerston in 1850. The responsibility of the cabinet to the prime minister is twofold; collective, in that, when he resigns the whole cabinet follows suit, a practice first (without prearrangement) adopted on the dismissal of the Pelhams in 1746, though not finally established till much later; and individual in that the prime minister appoints each member of the cabinet to his post and can at any time demand his resignation. As regards parliament, the responsibility is in the main collective, since the individual action of each is usually covered by the collective responsibility of all. "Each minister acts in his own department as the recognized agent of his colleagues in that particular department, subject, however, to enquiry and control by the whole body." And, if an individual minister takes publicly an independent line, either contrary to, or without consulting, the general opinion of his colleagues, it is usual, as has been shown above, for the prime minister to demand his resignation. But there have been cases when such individual or improper action, having been passed over by the prime minister, has been taken notice of by parliament in such a way, however, as not to involve the resignation of the cabinet. Thus in 1855 Lord John Russell resigned when Bulwer Lytton gave notice of a motion of censure on "the minister charged with negotiations at Vienna," and in 1865 Lord Westbury was forced to resign as a result of a motion of censure carefully worded so as to confine responsibility to the chancellor alone. Lastly, in speaking of the responsibility of the cabinet to the people, we mean something more than the continuous modification of policy by public opinion, something more than the increasing tendency of ministers in their parliamentary utterances to address the nation at large at least as much as their immediate hearers. The responsibility is greater and more direct than that, and is best illustrated by the practice, which in the last 100 years has become common, of dissolving parliament instead of resigning, on defeat, thus appealing from parliament to the people, and by that other practice now

generally followed of accepting the verdict of the electorate as final and resigning on defeat at the polls. (F. L. B.)

**Twentieth Century Developments.**—In July 1914 the cabinet system proved unequal to the demands imposed upon it by the diplomatic strain that led up to the declaration of war. In 1916 it had completely broken down. One of the salient characteristics of cabinet government was the secrecy of its discussions. The privacy of its meetings had been rigidly observed. No secretary was present, no minutes of proceedings were kept. On rare occasions a document called a "minute of the cabinet" was drawn up, the names of the ministers approving or disapproving were attached, and the record was placed in the archives of the sovereign. The prime minister was in the habit of writing to the sovereign after the cabinet meetings a short precis of its decisions, in the form of a confidential letter. Many of these letters are preserved in the royal archives, but they are not used for purposes of reference. Recent biographies and published correspondence of ministers show that important cabinet decisions were sometimes not acted upon through misunderstanding or forgetfulness.

So archaic was the system, so unsatisfactory its results, that in Aug. 1914 H. H. Asquith instituted a change in cabinet procedure. Some years before the war he had been provided with a secretariat for the purposes of the committee of imperial defence, over which as prime minister he presided. The services of this secretariat he adapted to the use of the prime minister himself and his cabinet in 1914. Up to that time the prime minister had not possessed a departmental staff, and no "office," other than a few private secretaries. Downing street contained no records. The evolution of the secretariat of the committee of imperial defence into the secretariat of the cabinet was, under the stress of the World War, natural and easy. When in 1916 D. Lloyd George became prime minister and superposed upon the cabinet of 23 the war cabinet of four or five, the cabinet secretariat was strengthened. By gradual processes inevitably arising out of the immense business accumulating in the hands of the head of the cabinet, owing to the closer relations with the dominions, by the ramifications of imperial defence which, as the war showed, affect every department of State, and by the growth of centralized Government, the institution of a "cabinet office" or prime minister's department was found to be and has remained an essential condition of directing the business of the nation.

As he was at its inception, so at the present time (1928) Sir Maurice Hankey is the head of the cabinet office and also of the defence committee secretariat. Suggestions have been made that the functions should be separated, but so far the opinion of those best qualified to judge is that the service to the prime minister would be less efficiently rendered if the present plan of one permanent civil servant in control of both secretariats were changed.

Since 1916, records of cabinet proceedings have been preserved. They are the property of the sovereign, their secrecy is safeguarded by the privy councillor's oath, and they are under the constitutional guardianship of the ministry for the time being. No public use can be made of them except by leave of the sovereign acting on the advice of the prime minister.

In normal times the tendency had been for the numbers of cabinet ministers to increase, until in 1914 there were 23 holders of cabinet office. In times of national difficulty and peril when legislative and departmental questions are subordinate to rapid decisions and executive action, the tendency has been to restrict the cabinet to the smallest possible number. It is impossible to predict the future of cabinet government, but those who have studied with care the tendencies of popular government in England incline to the view that the authority of the prime minister is more likely to be enhanced than shared by his cabinet colleagues. It does not seem probable that any serious attempt will be made to revert to the methods of conducting cabinet business which prevailed before 1916.

The cabinet meetings are held in Sir Robert Walpole's house, 10 Downing street, which he bequeathed to the nation, and which prime ministers continue to occupy to this day. For tables of the cabinets and ministers of the English Crown, see MINISTRY.

(E.)

## UNITED STATES

In the United States the president's cabinet is composed of the heads of the ten co-ordinate executive departments. But this is a matter of custom rather than of law, for the cabinet, as a collective body, has no legal existence or power. The Constitution contains no provision for a cabinet and makes only incidental reference to heads of departments, from whom the president may ask opinions. Neither did Congress, in creating the first three departments in 1789, recognize in any way the possibility of a cabinet council composed of the department heads. In fact, as the Constitution would seem to indicate, the Senate was then regarded as the real executive council on account of its powers to ratify treaties and confirm appointments.

Whatever may have been the views of the framers of the Constitution and of Congress, a cabinet, based on usage alone, early became a recognized part of the executive policy. Washington regarded the heads of the three executive departments and the attorney-general, who was not made the head of a department until later, as his confidential advisers, though the term cabinet was not immediately applied to them. He also exercised his constitutional power of requiring opinions from the chief executive officials, and took them into his confidence in all important matters of State. By this gradual process, he welded the department heads into an executive council, and by 1793 the term cabinet was generally applied to this group of presidential advisers. Gradually, as the administrative duties increased with the expanding nation, new executive departments were created by Congress and their heads became cabinet members. The three departments—State, Treasury and War—were established by the first session of Congress. The offices of attorney-general and postmaster-general, which were also created in 1789, did not rank as regular departments until 1870 and 1874, respectively, but the attorney-general, from the beginning, was considered a member of the cabinet and, upon the invitation of President Jackson, the postmaster-general became a member in 1829. Other department heads became members of the cabinet as follows: the Navy, in 1798, the Interior, in 1849, Agriculture, in 1889, Commerce and Labor, in 1903; however, the

latter department was divided in 1913 into two separate departments, that of Commerce and that of Labor, with separate heads.

As Prof. Munro points out in his book *The Government of the United States*, there is nothing done with the cabinet's consent which could not be done without its approval if the president should so decide. Yet it now meets regularly at stated times (usually once each week) fixed by the president. The meetings are not public, and no record is kept of transactions. Discussion is confined to whatever the president may see fit to lay before it, usually matters of importance relative to the general policy of the administration or any important piece of legislation desired by the president or by a cabinet member, and about to be submitted to Congress. (See GOVERNMENT DEPARTMENTS.)

The cabinet is the president's council in a very peculiar sense, in that its members are usually his personal selection. While the cabinet officers' nominations must be confirmed by the Senate, as a matter of practice, confirmation is given promptly and without objections. Department heads are appointed for the term of the administration; however, the president may dismiss any member at pleasure. In reality, dismissals are rare but individual resignations, due to the lack of harmony, are frequent. Congressional control over the various departments is limited to its powers to create and abolish executive offices; to give or withhold appropriations; to require reports and information; and to impeachment.

Between the English and American cabinets there is hardly a point of similarity. Members of the English cabinet must be members of one or the other branch of parliament; in America the members of the cabinet cannot be members of either house of Congress, nor can they be heard from the floor. In England the cabinet assumes the function of legislative leadership; this does not belong to the cabinet in the United States. In England the cabinet is responsible to the House of Commons, while in the United States the cabinet is responsible to the president alone. There follows a list of U. S. cabinets since the beginning. Owing to the slow evolution of the British cabinet (*see above*) from the old King's council corresponding British lists from 1603 are given under MINISTRY.

**CABINET**, a word with various applications which may be traced to two principal meanings, (1) a small private chamber, and (2) an article of furniture containing compartments formed of drawers, shelves, etc. The word is a diminutive of "cabin" and therefore properly means a small hut or shelter. From the use both of the article of furniture and of a small chamber for the safe-keeping of a collection of valuable prints, pictures, medals or other objects, the word is frequently applied to such a collection or to objects fit for such safe-keeping. The name of *Cabinet du Roi* was given to the collection of prints prepared by the best artists of the 17th century by order of Louis XIV. A "cabinet" edition of a literary work is one of somewhat small size, and bound in such a way as would suit a tasteful collection. The term is applied also to a size of photograph of a larger size than the *carte de visite* but smaller than the "panel."

**Early Cabinets.**—The artificer who constructs furniture is still called a "cabinet-maker," although the manufacture of cabinets, properly so called, is now a very occasional part of his work. Cabinets can be divided into a very large number of classes according to their shape, style, period and country of origin; but their usual characteristic is that they are supported upon a stand, and that they contain a series of drawers and pigeon-holes. The name is, however, now given to many pieces of furniture for the safe-keeping or exhibition of valuable objects, which really answer very little to the old conception of a cabinet. The cabinet represented an evolution brought about by the necessities of convenience, and it appealed to so many tastes and needs that it

rapidly became universal in the houses of the gentle classes, and in great measure took the impress of the peoples who adopted it. It would appear to have originated in Italy, probably at the very beginning of the 16th century. In its rudimentary form it was little more than an oblong box, with or without feet, small enough to stand upon a table or chair, filled with drawers and closed with doors. In this early form its restricted dimensions permitted of its use only for the safeguard of jewels, precious stones and money.

**Developments.**—As the Renaissance became general these early forms gave place to larger, more elaborate and more architectural efforts, until the cabinet became one of the most sumptuous of household adornments. It was natural that the countries which were earliest and most deeply touched by the Renaissance should excel in the designing of these noble and costly pieces of furniture. The cabinets of Italy, France and the Netherlands were especially rich and monumental. Those of Italy and Flanders are often of great magnificence and of real artistic skill, though like all other furniture their style was often grievously debased, and their details incongruous and bizarre. Flanders and Burgundy were, indeed, their lands of adoption, and Antwerp added to its renown as a metropolis of art by developing consummate skill in their manufacture and adornment. The cost and importance of the finer types have ensured the preservation of innumerable examples of all but the very earliest periods; and the student never ceases to be impressed by the extraordinary variety of the work of the 16th and 17th centuries, and very often of the 18th also. The basis of the cabinet has always been

wood, carved, polished or inlaid; but lavish use has been made of ivory, tortoise-shell, and those cut and polished precious stones which the Italians call *pietra dura*. In the great Flemish period of the 17th century the doors and drawers of cabinets were often painted with classical or mythological scenes. Many French and Florentine cabinets were also painted.

In many classes the drawers and pigeon-holes are enclosed by folding doors, carved or inlaid, and often painted on the inner sides. Perhaps the most favourite type during a great part of the 16th and 17th centuries—a type which grew so common that it became cosmopolitan—was characterized by a conceit which acquired astonishing popularity. When the folding doors are opened there is disclosed in the centre of the cabinet a tiny but palatial interior. Floored with alternate squares of ebony and ivory to imitate a black and white marble pavement, adorned with Corinthian columns or pilasters, and surrounded by mirrors, the effect, if occasionally affected and artificial, is quite as often exquisite. Although cabinets have been produced in England in considerable variety, and sometimes of very elegant and graceful form, the foreign makers on the whole produced the most elaborate and monumental examples. As we have said, Italy and the Netherlands acquired especial distinction in this kind of work. In France, which has always enjoyed a peculiar genius for assimilating modes in furniture, Flemish cabinets were so greatly in demand that Henry IV. determined to establish the industry in his own dominions. He therefore sent French workmen to the Low Countries to acquire the art of making cabinets, and especially those which were largely constructed of ebony and ivory. Among these workmen were Jean Macé and Pierre Boulle, a member of a family which was destined to acquire something approaching immortality. Many of the Flemish cabinets, so-called, which were in such high favour in France and also in England, were *armoires* (*q.v.*) consisting of two bodies superimposed, whereas the cabinet proper does not reach to the floor. Pillared and fluted, with panelled sides, and front elaborately carved with masks and human figures, these pieces which were most often in oak were exceedingly harmonious and balanced. Long before this, however, France had its own school of makers of cabinets, and some of their carved work was of the most admirable character. At a somewhat later date André Charles Boulle (*q.v.*) made many pieces to which the name of cabinet has been more or less loosely given. They were usually of massive proportions and of extreme elaboration of marquetry. The North Italian cabinets, and especially those which were made or influenced by the Florentine school, were grandiose and often gloomy. Conceived on a palatial scale, painted or carved, or incrustated with marble and *pietra dura*, they were intended for the adornment of galleries and lofty bare apartments where they were not felt to be overpowering. These North Italian cabinets were often covered with intarsia or marquetry, which by its subdued gaiety retrieved somewhat their heavy stateliness of form.

**Mingled Styles.**—It is, however, often difficult to ascribe a particular fashion of shape or of workmanship to a given country, since the interchange of ideas and the imports of actual pieces caused a rapid assimilation which destroyed frontiers. The close connection of centuries between Spain and the Netherlands, for instance, led to the production north and south of work that was not definitely characteristic of either. Spain, however, was more closely influenced than the Low Countries, and contains to this day numbers of cabinets which are not easily to be distinguished from the characteristic ebony, ivory and tortoise-shell work of the craftsmen whose skill was so rapidly acquired by the emissaries of Henry IV. The cabinets of southern Germany were much influenced by the models of northern Italy, but retained to a late date some of the characteristics of domestic Gothic work such as elaborately fashioned wrought-iron handles and polished steel hinges. Often, indeed, 17th-century south Germany work is a curious blend of Flemish and Italian ideas executed in oak and Hungarian ash. Such work, however interesting, necessarily lacks simplicity and repose.

A curious little detail of Flemish and Italian, and sometimes of French later 17th-century cabinets, is that the interiors of the

drawers are often lined with stamped gold or silver paper, or marbled ones somewhat similar to the "end papers" of old books. The great English cabinet-makers of the 18th century were very various in their cabinets, which did not always answer strictly to their name; but as a rule they will not bear comparison with the native work of the preceding century, which was most commonly executed in richly marked walnut, frequently enriched with excellent marquetry of woods. Mahogany was the dominating timber in English furniture from the accession of George II. almost to the time of the Napoleonic wars; but many cabinets were made in lacquer or in the bright-hued foreign woods which did so much to give lightness and grace to the British style. The glass-fronted cabinet for China or glass was in high favour in the Georgian period, and for pieces of that type, for which massiveness would have been inappropriate, satin and tulip woods, and other timbers with a handsome grain taking a high polish were much used.

(J. P.-B.)

**CABINET-MAKER**, one skilled in furniture-making and interior wood-work finish. (See FURNITURE MANUFACTURE.)

**CABINET NOIR**, the name given in France to the office where the letters of suspected persons were opened and read by public officials before being forwarded to their destination. This practice had been in vogue since the establishment of posts, but it was not until the reign of Louis XV. that a separate office was created for the purpose, called the *cabinet du secret des postes*, or more popularly the *cabinet noir*. Although denounced at the time of the Revolution, it was used both by the revolutionary leaders and by Napoleon. The *cabinet noir* as such has disappeared, but the right to open letters in cases of emergency and especially in time of war is exercised in all civilized countries. In England this power was confirmed by the Post Office Act of 1837; its most famous use being the opening of Mazzini's letters in 1844. (See ESPIONAGE and CENSORSHIP.)

**CABLE, GEORGE WASHINGTON** (1844–1925), American author, was born in New Orleans, La., on Oct. 12, 1844. The son of a Virginia father and a New England mother, he became a clerk at 15, fought two years for the Confederacy as a cavalryman, engaged in surveying and newspaper work, and then entered the counting-room of a cotton house. But all this time he was absorbing the charm of the Crescent City. Like his contemporary, Lafcadio Hearn, he pored over yellowed records, wandered in the old French quarter, studied alike the great creole families and the picturesque types of the levee. His tales, based on this life, appeared first in *Scribner's Monthly*; then, in 1879, were collected in book form under the title, *Old Creole Days*. With the possible exception of *Madame Delphine* (1881), Cable's art reached its highest point in this first volume. The delicacy of his portrayal of the exotic background of the southland, the deftness of his dialogue, the bewitching grace and dignified gallantry of his characters all rank the tales high in the local colour movement of the later 19th century. *Strange True Stories of Louisiana* (1889) also partakes of this charm, which in the best of his novels *The Grandissimes* (1880) is darkened and deepened by the shadow of slavery. Old feuds between haughty clans dating back to the early days of settlement, shifting glimpses of voodoo rites and carnival balls, of thick canebrakes and the French market, of feverish gambling and busy commerce, a gallery of characters, make the book almost an epitome of Louisiana history. But as a romancer Cable fails somewhat in constructive power, this fault being even more prominent in two of his other early and somewhat distinguished novels, *Dr. Sevier* (1885), a study of the Civil War period, and *Bonaventure* (1888), a pastoral chronicle of outlying Louisiana and the "Cajun" descendants of the refugees from Grand-Pré. Although Cable continued writing until his death in St. Petersburg, Fla., on Jan. 31, 1925, his later fiction is distinctly inferior to his first books; and his studies belonging more specifically to the field of social history such as *The Creoles of Louisiana* (1884) and *The Negro Question* (1890) are not outstanding. After 1885 Cable made his home in Northampton, Mass., occupying himself with home culture clubs and with giving many readings from his works. It is not, however, as teacher or reformer, but as chronicler of the Crescent City, of the sluggish bayous and sunlit

meadows of the lower Mississippi, and as portrayer of the descendants of the early French and Spanish inhabitants that his reputation is secure.

**CABLE**, a large rope or chain, used generally with ships, but often employed for other purposes; the term "cable" is also used for minor varieties of similar engineering or other attachments, and in the case of "electric cables" for the grouped and sheathed

FIG. 1.—TWO LENGTHS OF CHAIN CABLE COUPLED BY A "JOINING SHACKLE"

The end links (C) are made without studs in order to take the shackle. The adjacent links (B) are made larger to take the big studless links. The shackle (D) is shown. The bolt of the shackle is secured by a steel pin and lead pellet

wires by which telegraphic and telephonic messages are transmitted. See TELEGRAPH and TELEPHONE.

The cables by which ships ride at anchor are made of chain. Prior to 1811 only hempen cables were supplied to ships of the British navy; but in that year chain cables were supplied, as less liable to foul or be cut by rocks, or to be injured by enemy's shot. They are also handier and cleaner. The first patent for chain cables was by Philip White in 1634; twisted links were suggested in 1813 by Captain Brown; studs were introduced in 1816.

In manufacturing chain cables, the bars are cut to the required length of link, at an angle for forming the welds and, after heating, are bent by machinery and welded by smiths, each link being inserted in the previous one before welding.

Cables for the British navy and mercantile marine are supplied in 12½-fathom and 15-fathom lengths respectively, connected together by "joining shackles," D (fig. 1).

Each length is "marked" by pieces of iron wire being twisted round the studs of the links; the wire is placed on the first studs on each side of the first shackle, on the second studs on each side of the second shackle, and so on; thus indicating the number of lengths of cable that is out. In joining the lengths together, the round end of the shackle is placed towards the anchor. The end links of each length (C.C.) are made without studs in order to take the shackle; but as studs increase the strength of a link, in a studless or open link the iron is of greater diameter. The next links (B.B.) have to be enlarged, in order to take the increased size of the links C.C. In the joining shackle (D), the bolt is oval, its greater diameter being in the direction of the strain. The bolt of a shackle, which attaches the cable to the anchor (called an "anchor shackle" to distinguish it from a joining shackle) projects and is secured by a forelock; but since any projection in a joining shackle would be liable to be injured when the cable is running out or when passing round a capstan, the bolts are made as shown (in D), and are secured by a smaller pin.

The inboard ends of cables are secured by a "slip" which prevents the cable's inner end from running overboard, and also enables the cable to be "slipped," or let go, in case of emergency. In the British navy, swivel pieces are fitted in the first and last lengths of cable, to prevent turns getting into the cable, caused

FIG. 2.—MOORING SWIVEL, PUT IN THE CABLES OF A WARSHIP WHEN SHE IS RIDING BY TWO ANCHORS, TO PREVENT THE CABLES FOULING EACH OTHER AS THE SHIP SWINGS. MOORING SWIVELS ARE SELDOM USED IN THE MERCANTILE MARINE

by the ship swinging round her anchor. If a ship is moored with two anchors, the cables are secured to a mooring swivel (fig. 2), which prevents a "foul hawse," i.e., the cables being entwined round each other. The cable is generally hove in by either a power-driven capstan or windlass (see CAPSTAN). Ships in the British navy used to ride by a compressor, a long steel arm, pivoted under the forecastle so that it can be swung across the deck pipe and jam the cable (fig. 3), but modern warships are fitted with slips just below the cable holder for this purpose. The cable-holder is used for checking cable running out. When a ship has been given the necessary cable, the compressor is "bowed to"

FROM "MANUAL OF SEAMANSHIP" BY PERMISSION OF CONTROLLER OF H.M. STATIONERY OFFICE

FIG. 3.—PLAN AND SECTION OF A COMPRESSOR SHOWING PARTS  
Older ships of the British Navy are fitted to ride by a compressor but in more modern British men-o'-war a Blake slip stopper, fitted just below the cable holder, takes the place of this contrivance

or the slip put on, and the brake of the cable-holder is eased up. Small vessels of the mercantile marine ride by turns round the windlass; in larger or more modern vessels fitted with a steam windlass, the friction brakes take the strain, aided, when required in bad weather, by the bits, compressor or controller.

See the Admiralty *Manual of Seamanship*, vol. i. (H.M. Stationery Office, London).

**CABLE-HOLDER:** see CAPSTAN.

**CABLE MOULDING** (sometimes called ROPE MOULDING), in architecture, a convex moulding, spirally carved, so that it resembles a rope. Its most common use is as one of the mouldings decorating recessed doorways of the Romanesque and Gothic periods. The word "cabling" designates a convex moulding sunk in the flutes of a classical column, usually in the lower portion of the shaft; this is also known as "reeding."

**CABLE TRANSFERS**, the immediate transfer of money from one country to another by the use of cablegram. A person in New York for instance, wishing to put in the hands of a person in London a certain sum of money at once, can do so by procuring a cable transfer from a foreign exchange banker. Upon the deposit by the transferor of the proper amount of money the New York bank will cable its London branch or correspondent to pay the designated sum at once to the payee in that city. The payee is notified, generally by the London agent, occasionally by cable by the New York bank, as to where and when to call for his funds.

The cable rate of exchange is so arranged as to be sufficient to enable the bank to procure the necessary funds and also to allow a slight profit on the transaction. It is higher than the cheque or time rate because the bank selling the cable transfer

expects its correspondent to pay it at once, whereas, in the case of a cheque transfer or time transfer it may still have the use of its foreign funds for some time after the transfer is sold. Cable transfers are payable upon the arrival of the cable; between the United States and England, owing to difference in time and the interim necessary for notifying the payee, they are usually paid on the day after the sale.

**CABOCHE, SIMON**, Simon Lecoustellier, called "Caboche," a skinner of the Paris Boucherie. He was prominent in the seditious disturbances which broke out in Paris in April and May, 1413. When the butchers had made themselves masters of Paris, Caboche became bailiff (*huissier d'armes*) and warden of the bridge of Charenton. After the fall of the *Cabochien* party on Aug. 4, he fled to Burgundy.

See Colville, *Les Cabochiens et l'ordonnance de 1413* (1888).

**CABOT, GEORGE** (1751-1823), American political leader, was born in Salem, Mass., on Dec. 16, 1751. He studied at Harvard from 1766 to 1768, when he went to sea as a cabin boy. He gradually rose to become a shipowner and a successful merchant, retiring from business in 1794. Throughout his life he was much interested in politics, and exercised, as a contributor to the press and through his friendships, a powerful political influence, especially in New England. He was a member of the Massachusetts Constitutional Convention of 1779-80, of the State senate in 1782-83, of the convention which in 1788 ratified for Massachusetts the Federal Constitution, and from 1791 to 1796 of the U.S. Senate. Among the bills introduced by him in the Senate was the Fugitive Slave Act of 1793. Upon the establishment of the navy department in 1798, he was appointed and confirmed as its secretary, but he never performed the duties of the office. In 1814-15 Cabot was the president of the Hartford Convention, and as such was then and afterwards acrimoniously attacked by the Republicans throughout the country. He died in Boston on April 18, 1823.

See Henry Cabot Lodge, *Life and Letters of George Cabot* (Boston, 1877).

**CABOT, JOHN** (GIOVANNI CABOTO) (1450-1498), Italian navigator and explorer of North America, was born in Genoa, but in 1461 went to live in Venice, of which he became a naturalized citizen in 1476. During one of his trading voyages to the eastern Mediterranean, Cabot visited Mecca, then the greatest mart in the world for the exchange of the goods of the East for those of the West. Filled with the idea that it would be shorter and quicker to bring these goods to Europe by sea, if a route could be found, Cabot, about 1484, removed with his family to London. His plans were explained to the leading merchants of Bristol, from which port an extensive trade was already carried on with Iceland. It was decided that an attempt should be made to reach the "island of Brazil" or that of the "Seven Cities," placed on mediaeval maps to the west of Ireland, as the first halting-places on the route to Asia by the west.

To find these islands vessels were despatched from Bristol during several years, when in 1493 news reached England that another Genoese, Christopher Columbus, had reached the Indies. It was decided to forego further search for the islands and to push straight on to Asia, and letters patent for the purpose were issued on March 5, 1496 by Henry VII., granting to his "well-beloved John Cabot, citizen of Venice, to Lewis, Sebastian and Santius, sonnes of the said John, full and free authority, leave and power upon their own proper costs and charges, to seeke out, discover and finde whatsoever isles, countries, regions or provinces of the heathen and infidels, which before this time have been unknown to all Christians." Merchandise from the countries visited was to be entered at Bristol free of duty, but one-fifth of the net gains was to go to the king.

Armed with these powers, Cabot set sail from Bristol on Tuesday, May 2, 1497, on board a ship called the "Mathew," manned by 18 men. Rounding Ireland, they headed first north and then west. After being 52 days at sea, at five o'clock on Saturday morning, June 24, they reached the northern extremity of Cape Breton island. The royal banner was unfurled, and Cabot took possession of the country in the name of King Henry VII. The soil being found fertile and the climate temperate, Cabot was

convinced he had reached the north-eastern coast of Asia, whence came the silks and precious stones he had seen at Mecca. Cape North was named Cape Discovery, and as the day was the festival of St. John the Baptist, St. Paul island, which lies opposite, was called the island of St. John. Sailing north, Cabot named Cape Ray, St. George's Cape, and christened St. Pierre and Miquelon, which then with Langley formed three separate islands, the Trinity group. Cape Race, the last land seen, was named England's Cape. On Sunday, Aug. 6, the "Mathew" dropped anchor once more in Bristol harbour. On Aug. 10 Cabot received from the king £10 for having "found the new isle." He reported that 700 leagues beyond Ireland he had reached the country of the Grand Khan. He intended on his next voyage to follow the coast southward as far as Cipangu or Japan, then placed near the equator. Once Cipangu had been reached London would become a greater centre for spices than Alexandria. Henry VII. granted Cabot a pension of £20, and promised him in the spring a fleet of ten ships with which to sail to Cipangu.

On Feb. 3, 1498, fresh letters patent were issued. Henry VII. himself also advanced considerable sums of money to various members of the expedition. In the spring Cabot visited Lisbon and Seville, to secure the services of men who had sailed along the African coast with Cam and Diaz or to the Indies with Columbus. At Lisbon he met a certain João Fernandes, called Llavrador, who about the year 1492 appears to have made his way from Iceland to Greenland. Cabot, on learning from Fernandes that part of Asia, as they supposed Greenland to be, lay so near Iceland, determined to return by way of this country. On reaching Bristol he laid his plans accordingly. Early in May the expedition, which consisted of two ships and 300 men, left Bristol. Several vessels in the habit of trading to Iceland accompanied them. Off Ireland a storm forced one of these to return, but the rest of the fleet proceeded on its way along the parallel of 58°. Each day the ships were carried northward by the Gulf Stream. Early in June Cabot reached the east coast of Greenland, and as Fernandes was the first who had told him of this country he named it the Labrador's Land.

In the hope of finding a passage Cabot proceeded northward along the coast. As he advanced, the cold became more intense and the icebergs thicker and larger. It was also noticed that the land trended eastward. On June 11, in lat. 67° 30' the crews mutinied, and refused to proceed farther in that direction. Cabot had no alternative but to put his ships about. Rounding Cape Farewell, he explored the southern coast of Greenland and then made his way a certain distance up the west coast. Here again his progress was checked by icebergs, whereupon a course was set towards the west. Crossing Davis strait, Cabot reached our modern Baffin Land in 66°. Judging this to be the Asiatic mainland, he set off southward in search of Cipangu. South of Hudson strait a little bartering was done with the Indians, but these could offer nothing in exchange but furs. Our strait of Belle Isle was mistaken for an ordinary bay, and Newfoundland was regarded by Cabot as the main shore itself. Rounding Cape Race, he visited the region explored before and then followed the coast as far south as the 38th parallel, when the absence of all signs of eastern civilization and the low state of his stores forced him to abandon all hope of reaching Cipangu on this voyage. Accordingly, a course was set for England, where they arrived safely late in the autumn of 1498. Not long after his return John Cabot died.

His son, SEBASTIAN CABOT (c. 1476-1557), is not independently heard of until May 1512, when he was paid 20 shillings "for making a card of Gascoigne and Guyenne," whither he accompanied the English army sent that year by Henry VIII. to aid his father-in-law Ferdinand of Aragon against the French. Sebastian was questioned about the Newfoundland coast by Ferdinand's councillors, and as a result was appointed a captain in the navy at a salary of 50,000 maravedis a year. Preparations were made for him to set sail in March 1516; but the death of the king in January of that year put an end to the undertaking. His services were retained by Charles V., and on Feb. 5, 1518, Cabot was named Pilot Major and official examiner of pilots.

In the winter of 1520-21 Sebastian Cabot returned to England, and while there was offered by Wolsey the command of five vessels which Henry VIII. intended to despatch to Newfoundland. Being reproached by a fellow Venetian with having done nothing for his own country, Cabot refused, and on reaching Spain secretly negotiated with the Council of Ten at Venice. On March 4, 1525 he was appointed commander of an expedition fitted out at Seville, "to discover the Moluccas, Tarsis, Ophir, Cipango and Cathay."

The three vessels set sail in April, and by June were off the coast of Brazil and on their way to the Straits of Magellan. Near the La Plata river Cabot found three Spaniards who had formed part of the De Solis expedition of 1515. These men gave such glowing accounts of the riches of the country that Cabot was induced to forego the search for Tarsis and Ophir and to enter the La Plata, which was reached in Feb. 1527. On reaching Seville in Aug. 1530, Cabot was condemned to four years' banishment to Oran in Africa, but in June 1533 he was once more reinstated in his former post of Pilot Major, which he continued to fill until he again removed to England.

As early as 1538 Cabot tried to obtain employment under Henry VIII., and it is possible he was the Seville pilot who was brought to London by the king in 1541. Soon after the accession of Edward VI., however, his friends induced the Privy Council to advance money for his removal to England, and on Jan. 5, 1549 the king granted him a pension of £166.13s.4d. Two applications from Spain (in 1550 and 1553), for his repatriation were refused, the first by the privy council and the second by Queen Mary herself.

On June 26, 1550 Cabot received £200 "by waie of the kinges Majesties rewarde," but it is not clear whether this was for his services in putting down the privileges of the German Merchants of the Steelyard or for founding the company of Merchant Adventurers incorporated on Dec. 18, 1551. Of this company Cabot was made governor for life. Three ships were sent out in May 1553 to search for a passage to the East by the north-east. Two of the vessels were caught in the ice near Arzina and the crews frozen to death. Chancellor's vessel alone reached the White Sea, whence her captain made his way overland to Moscow. He returned to England in the summer of 1554 and was the means of opening up a very considerable trade with Russia. Vessels were again despatched to Russia in 1555 and 1556. On the arrival of King Philip II. in England Cabot's pension was stopped on May 26, 1557, but three days later Mary had it renewed. The date of Cabot's death has not been definitely discovered. It is supposed that he died within the year.

Markham in *Geographical Journal* (1897); *Proceedings of the Royal Society of Canada*, vol. iii. (1897); G. P. Winship, *Cabot Bibliography, with an Introductory Essay on the Careers of the Cabots* (1900); H. P. Biggar, "The Voyages of the Cabots," in *Revue Hispanique*, vol. x. (1903); J. E. Olson and E. G. Bourne eds., *The Northmen, Columbus and Cabot, 985-1503* (1906); and A. P. Newton, "An Early Grant to Sebastian Cabot," *English Hist. Rev.*, vol. xxxvii., p. 564-565 (1922).

**CABOTAGE**, the French term for coasting-trade, a coast-pilotage. It is probably derived from *cabot*, a small boat, with which the name Cabot may be connected; the conjecture that the word comes from *cabo*, the Spanish for cape, and means "sailing from cape to cape," has little foundation.

**CABRA**, a town of southern Spain, in the province of Cordova, 28m. S.E. of Cordova, on the Jaén-Málaga railway. It is built on the river Cabra in the fertile valley between the Sierra de Cabra and the Sierra de Montilla. Pop. (1920) 14,951. Cabra has a ruined Moorish castle and a parish church which was originally a mosque, and later a cathedral, when for several centuries Cabra was an episcopal see. There are marble quarries near the town, which makes bricks and pottery, coarse cloth and felt, and is the market for local grain, wine, olive oil and fruit. Cabra (Roman Baebro or Aegabro) was delivered from the Moors by Ferdinand III. of Castile in 1244 and entrusted to the Order of Calatrava. Recaptured by the Muslims in 1331, it was finally reunited to Christian Spain a century later.

**CABRERA, RAMON** (1806-1877), Carlist general, was born at Tortosa, province of Tarragona, Spain, on Dec. 27, 1806. He took minor orders, but the bishop refused to ordain him as a priest, telling him that the army, not the church, was his vocation. Cabrera took part in Carlist conspiracies on the death of Ferdinand VII. The authorities exiled him, and he absconded to Morella to join the forces of the pretender Don Carlos. In a very short time he rose by sheer daring, fanaticism and ferocity to the front rank among the Carlist chiefs who led the bands of Don Carlos in Catalonia, Aragon and Valencia. He was many times wounded in the brilliant fights in which he again and again defeated the generals of Queen Isabella. He sullied his victories by acts of cruelty, shooting prisoners of war whose lives he had promised to spare, and not respecting the lives and property of non-combatants. The queen's generals seized his mother as a hostage, whereupon Cabrera shot several mayors and officers. Gen. Noguera unfortunately caused the mother of Cabrera to be shot, and the Carlist leader then started upon a policy of reprisals so merciless that the people nicknamed him "The Tiger of the Maeztazgo." He shot 1,110 prisoners of war, 100 officers, and many civilians, including the wives of four leading Isabellinos, to avenge his mother. When Marshal Espartero induced the Carlists of the north-western provinces, with Maroto at their head, to submit in accordance with the Convention of Vergara, which secured the recognition of the rank and titles of 1,000 Carlist officers, Cabrera held out in Central Spain for nearly a year. Marshals Espartero and O'Donnell, with the bulk of the Isabellino armies, had to conduct a long and bloody campaign against Cabrera before they succeeded in driving him into French territory in July 1840. The government of Louis Philippe incarcerated him for some months and then allowed him to go to England, where he quarrelled with the pretender, disapproving of his abdication in favour of the count of Montemolin. In 1848 Cabrera reappeared in the mountains of Catalonia at the head of Carlist bands. These were soon dispersed and he again fled to France. He did not take a very active part in the subsequent risings of the Carlists, who, however, continued to consult him. In March 1875 Cabrera presented to Don Carlos a manifesto in which he called upon the adherents of the pretender to follow his own example and submit to the restored monarchy of Alphonso XII. Cabrera, who was ever afterwards regarded with contempt and execration by the Carlists, died in London on May 24, 1877.

**CABRILLO NATIONAL MONUMENT**, a tract of 1 ac. in the southern part of California, U.S.A., set apart as a Government reservation in 1913. It was at or near this point that Juan Rodríguez Cabrillo first saw the California mainland on Sept. 28, 1542. The reservation is administered by the War Department.

**CABRIOLET**, originally, a name given by the English to a two-wheel, horse-drawn vehicle with a hood, for gentleman's driving. In America, a name given to a horse-drawn vehicle with a coachman's seat over a panel framework (in distinction from a victoria which is similar, but of iron skeleton construction). It had a seat behind at a lower level with a collapsible leather hood and was a fashionable vehicle for ladies. *See* CAB.

**CA' CANNY**. Ca' canny (or "Go canny") is by origin a Scottish phrase meaning to go cautiously, or warily, or, by a slight change of meaning, to go slow. Thus, in John Galt's *The Provost*, we read "We maun ca' canny many a day yet before we think of dignities," and, in the same writer's *The Entail*, "But, Charlie and Bill, ca' canny." In modern times, the phrase has acquired a special meaning in relation to industrial strife. To "ca' canny" is to work slowly, in order to draw attention to a workshop grievance, or bring pressure to bear upon an employer. It appears to have been first used in this sense in a dispute at the Glasgow docks in 1889, when the dockers had struck for a rise in wages. Agricultural labourers were introduced as blacklegs, and the employers expressed themselves as highly satisfied with their work. When the dockers had to go back on the old terms, their leader adjured them, since the blacklegs had given satisfaction, to work like them, to ca' canny. During the following years the phrase caught on, and a pamphlet recommending it as a policy

to trade unionists was published in 1895. Later, the phrase was taken up by the French Syndicalists, and identified by them with the less violent forms of *sabotage* (q.v.). (See E. Pouget, *Le Sabotage* [n.d].)

Ca' canny, as the term is used in Great Britain, is essentially an occasional practice. It is not authorized by any important trade union, but is sometimes adopted spontaneously by a group of workers in some particular factory as a means of securing redress for a felt grievance. Thus, if the men think the management is unduly speeding up the pace of work, they may make a concerted effort to "speed down"; if they think piecework prices are too low they may deliberately restrict production in order to draw attention to their grievance, or they may ca' canny temporarily because of some dispute about the arrangement of work, workshop discipline, or the like. The more deliberate kind of ca' canny is sometimes known by the name of the "stay-in strike," in which the men, by a concerted arrangement, remain at work, but do as little as possible. A variant of this is the "working to rule" policy, found especially on the railways, where the men sometimes, in furtherance of a grievance, tangle up the traffic by strict obedience to all the rules laid down for them, well knowing that these are not literally workable without entire disorganization.

The term ca' canny is also known in the United States, where it has much the same sense as in Great Britain. It appears, however, to be used more often in order to describe a systematic policy, whereas the occasional practice of "go slow" methods is, in America, commonly known as "striking on the job."

As an organized practice, ca' canny is not very common. It occurs, apart from short-lived and purely spontaneous movements arising out of a particular workshop grievance, mainly where there is a long-standing bad relationship between employers and workers. It appears to have been far commoner in France, during the Syndicalist activity before the World War, and to have been also widespread in Italy. In Germany there is little sign of it. Save as an occasional method of expressing a local grievance, it is important mainly as a part of the deliberate policy of revolutionary Syndicalism in France and Italy, and industrial unionism in the English-speaking countries.

Apart from industrial disputes, the name "ca' canny" is sometimes applied to a deliberate and systematic slowing down of the pace of production, either in order to make the work last longer, or to create additional employment, or to express a general dissatisfaction with the economic system. While "going slow" may be justified as a purely temporary expedient for calling attention to a particular grievance, its systematic use is obviously more likely, by increasing the cost of production, to create unemployment than employment. (G. D. H. C.)

**CACCINI, GIULIO** (1558-1615?), Italian composer, also known as Giulio Romano, but to be distinguished from the painter of that name, was born at Rome about 1558, and in 1578 entered the service of the grand duke of Tuscany at Florence. He collaborated with J. Peri in the early attempts at musical drama which were the ancestors of modern opera (*Dafne*, 1594, and *Euridice*, 1600), produced at Florence by the circle of musicians and amateurs which met at the houses of G. Bardi and Corsi. He also published in 1601 *Le nuove musiche*, a collection of songs which is of great importance in the history of the art as one of the earliest essays in monodic music. He was a lyric composer rather than a dramatist like Peri, and the genuine beauty of his works makes them acceptable even to-day.

**CÁCERES**, a province of western Spain, formed in 1833 of districts taken from Estremadura. It is bounded on the north by Salamanca and Ávila, on the east by Toledo, on the south by Badajoz, and on the west by Portugal. Pop. (1920) 410,032; area, 7,667 sq. miles. Cáceres is the largest of the Spanish provinces, after Badajoz, and one of the most thinly peopled. It consists mainly of a broad, undulating plain, rising to the Sierra de Gata and Sierra de Grédos in the north, and to lower ranges in the south and south-east. All the province, except a small area on the south-east, is drained by the river Tagus, which flows through it from east to west, and is joined by several tributaries, notably the Alagón and Tietar on the north and the Salor and

Almonte on the south. The climate is temperate except in summer, when hot east winds prevail. Droughts are common in many districts and forests are confined to the north, where the cork oak is important. Much of the province is covered with thin pasture. The region north of the Tagus is more fertile than that to the south and produces fair crops of cereals, olives, peas and fruit, but agriculture everywhere is backward. As a stock-breeding province Cáceres ranks second only to Badajoz. In 1924 it possessed many pigs, over 1,000,000 sheep and more goats than any other province. It is famous for the wool, ham and red sausages, called *embutidos*, which it exports. Its mineral wealth is small but it produces all the phosphates mined in Spain (1924, about 5,000 tons) and small quantities of zinc, lead and tin. Leather, coarse woollen and cork goods are produced in many towns, but owing to the general poverty, the scattered population, the lack of good roads and the backwardness of education, there is no real industrial development. The North Madrid-Lisbon railway which crosses the province from east to west is joined at Plasencia by a line from Salamanca and at Arroyo by a branch through Cáceres, the capital, to Mérida in Badajoz on the South Madrid-Lisbon line. The principal towns: Cáceres, pop. (1920) 23,563; Valencia de Alcántara, 12,024; Trujillo, 11,476; Plasencia, 10,002; and Alcántara, 3,954, are described in separate articles. Other towns are: Arroyo del Puerco, 8,402; Majadas, 6,782; Logrosán, 6,033; Garrovillas, 6,008; and Brozas, 5,424. (See also ESTREMADURA.)

**CÁCERES**, capital of the Spanish province described above, about 14m. S. of the river Tagus, on a branch railway from Arroyo de Malpartida, on the North Madrid-Lisbon line, to Mérida on the south line. Pop. (1920) 23,563. Cáceres, built on a conspicuous eminence on a low east-west ridge, consists of two towns, an old and a new. The old, upper town, with its mediaeval palaces, turrets and massive walls, half Roman and half Arab, is dominated by the lofty tower of the Gothic church of San Mateo. The once famous monastery and college of the Jesuits is now a hospital. Steep steps lead down through four gates to the lower, modern town containing the law courts, town hall, schools and the palace of the bishops of Cória (pop. 3,152), a town on the river Alagon. Cáceres makes cork and leather goods, pottery and cloth, and exports grain, oil, live-stock, wool, sausages and phosphates from the neighbouring mines. Cáceres, of Roman origin, probably occupies the site of "Norba Caesarina."

**CACHALOT**, a name for *Physeter catodon*, the sperm-whale (q.v.).

**CACHAR** or **KACHAR**, a district of British India, in the province of Assam. It occupies the upper basin of the Surma or Barak river, and is bounded on three sides by lofty hills. Its area is 3,654 sq. miles. Pop. (1921) 527,228. It is divided naturally between the plain and hills. The scenery is beautiful, the hills generally rising steeply and being clothed with forests, while the plain is relieved of monotony by small isolated undulations and by its rich vegetation. The Surma is the chief river, and its principal tributaries from the north are the Jiri and Jatinga, and from the south the Sonai and Dholeswari. Several extensive fens, notably that of Chatla, which become lakes in time of flood, are characteristic of the plain. This is alluvial and bears heavy crops of rice, next to which in importance is tea. The industry connected with the latter crop employs large numbers; the tea garden population was 137,733 in 1921, when there were 59,000 ac. under tea, with an output of nearly 21 million pounds. An oil field at Badarpur is worked by the Burma Oil company; over four and one-quarter million gallons of crude oil were extracted in 1925. Manufacturing industries are otherwise slight. Reserved forests extend over nearly 1,200 sq. miles. Elephants abound in the North Cachar hills. The Assam-Bengal railway serves the district, including the headquarters town of Silchar. The plain is the most thickly-populated part of the district; in the North Cachar hills the population is sparse (16 per sq. mile). The district takes its name from the former rulers of the Kachari tribe, who settled here early in the 18th century. About the close of that century the Burmans threatened to expel the Kachari rajah and annex his territory; the British, however, intervened to pre-

vent this, and on the death of the last rajah without heir, in 1830, they obtained the territory under treaty. A separate principality, which had been established in the North Cachar hills earlier in the century by a servant of the rajah, was taken over by the British in 1854, owing to the misconduct of its rulers. The southern part of the district was raided several times in the 19th century by the turbulent Lushai.

**CACHE**, a store or hiding place, generally a hole dug in the ground for concealing provisions, etc.; also the goods so hidden. A series of caches is sometimes laid on long expeditions, as in Arctic exploration, to provide stores for the return journey.

**CACHIN, MARCEL** (1869— ), French politician, one of the principal leaders of the French Communist Party, was born at Paimpol, Brittany, and adopted teaching as a profession. He was a master in a Bordeaux *lycée* when he joined the Socialist movement. His party, thanks to common action between the reactionaries and the socialists against the moderate republicans, captured the municipal government of the city, and Cachin was nominated *adjoint* to the mayor. Later, he settled in Paris, and was elected to the municipal council of the city. In May 1914 he became one of the deputies for Paris in the Chamber, in which he sat continuously from that time forward. For many years he was one of the most moderate members of the Socialist group, and during the World War showed a patriotic spirit. In Dec. 1918 he accompanied Poincaré and Clemenceau to Metz and Strasbourg. But shortly his attitude underwent a sudden change. Having become director of the paper *Humanité*, he went to Moscow, and became a convert to Bolshevism. He is the principal leader in the Chamber of the Communist Party. In 1927 he was condemned to some months' imprisonment for inciting soldiers and sailors to revolt, and was incarcerated in the Santé prison with other deputies and Communist agitators sentenced for similar offences. (P. B.)

**CACHOEIRA**, an inland commercial centre of the State of Bahia, Brazil. It lies on the Paraguassú river, about 40 m. from its mouth at the head of the Bahia (or Bay) Todos os Santos, from which the town and State of Bahia take their name. Cachoeira has a population (1920) of about 9,000. The products of the countryside are rice, cereals and tobacco. The town has a meat-preserving plant, cotton and cigar factories and potteries. It is reached by steamer from Bahia, about 48 m. distant. It is the terminus of a short railway (28 m.) north to Feira de Santa Ana, and from Sao Felix, opposite Cachoeira across the Paraguassú river, another railway runs westward to Machado Portella, 161 m., both lines being portions of the Bahia Central railway system.

**CACIQUE**, the name adopted by the Spaniards at the time of the discovery of America for a native chief or ruler. It is sometimes also applied to a bird, *Cassicus*, of the icterine family (see *ICTERUS*).

**CACODYL**, a colourless liquid which is spontaneously inflammable in air, has an intolerable smell and belongs to the group of organo-arsenical compounds (see *ARSENIC: Organic Derivatives*).

**CACTUS**. This word, applied by the ancient Greeks to some prickly plant, was adopted by Linnaeus as the name of a group of curious succulent or fleshy-stemmed plants, most of them prickly and leafless, some of which produce beautiful flowers, and are now popular in gardens. As applied by Linnaeus, the name *Cactus* is almost conterminous with what is now the family *Cactaceae*.

The *Cacti* may be described in general terms as plants having a woody axis, or skeleton, overlaid with thick masses of cellular tissue forming the fleshy stems. These are extremely various in character and form, being globose, cylindrical, columnar or flattened into leafy expansions of thick joint-like divisions, the surface being either ribbed like a melon, or developed into nipple-like protuberances, or variously angular, or smooth, but in the greater number of species furnished copiously with tufts of horny spines, some of which are exceedingly keen and powerful. These tufts show the position of buds, of which, however, comparatively few are developed. The leaves, if present, are generally much reduced. In *Pereskia*, however, the stems are less succulent, and the leaves, though fleshy, are developed in the usual form. The flowers are frequently large and showy, and are often attractive from their

high colouring. In one group, represented by *Cereus* and related genera, they consist of a tube, elongated, on the outer surface of which, towards the base, are developed small and at first inconspicuous scales, which gradually increase in size upwards and at length become crowded, numerous and petaloid, forming a funnel-shaped blossom, the beauty of which is much enhanced by the multitude of conspicuous stamens which with the pistil occupy

FIG. 1.—CACTUS FENCES IN SOUTHERN MEXICO

the centre. In another group, represented by *Opuntia*, the flowers are rotate; i.e., the long tube is replaced by a very short one. At the base of the tube, in both groups, the ovary develops into a fleshy (often edible) fruit, that produced by the *Opuntias* being known as the prickly pear or Indian fig.

Genera with long-tubed flowers include *Echinocactus*, *Echinopsis*, *Cereus*, *Epiphyllum*, *Cephalocereus* and many others, while

FIG. 2.—PRICKLY PEAR CACTUS

The illustration shows the flattened branch of swollen stem which stores up water and spiny leaves which reduce transpiration

those with short-tubed flowers are *Rhipsalis*, *Opuntia*, *Pereskia* and several of minor importance. *Cactaceae* belong to the New World; but some of the *Opuntias* have been long distributed on the shores of the Mediterranean and the volcanic soil of Italy and several species of *Rhipsalis* occur in tropical Asia and Africa. They mostly affect the hot, dry regions of tropical America, the aridity of which they are enabled to withstand in consequence of the thickness of their cuticle and the fewness and "sunk" condition of the stomata with which they are furnished. The thick

fleshy stems and branches contain a store of water. The succulent fruits of some kinds are not only edible but agreeable, and in fevers are freely administered as a cooling drink. The Spanish-Americans plant the *Opuntias* and others around their houses, where they serve as impenetrable fences.

**CACTUS** (fig. 1), the genus of melon-thistle or Turk's cap cactuses, contains about 18 species, which are found in the West Indies, Mexico, Venezuela and Colombia. The typical species, *Cactus melocactus*, of Jamaica, forms a succulent mass of ovoid form, from 1 to 2 ft. high, the surface divided into numerous furrows like the ribs of a melon, with projecting angles, which are set with a regular series of stellated spines—each bundle consisting of about five larger spines, accompanied by smaller but sharp bristles—and the top of the plant being surmounted by a cylindrical crown 3 to 5 in. high, composed of reddish-brown, needle-like bristles, closely packed with cottony wool. At the summit of this crown the small rosy-pink flowers are produced, half protruding from the mass of wool, and these are succeeded by small red or pink, elongated berries. These plants usually grow in rocky places with little or no earth to support them. The fruit of this and related species, which has an agreeably acid flavour, is eaten in the West Indies. The group is distinguished by the distinct *cephalium* or crown which bears the flowers. *Disocactus*, a related genus, consists of about 7 species native to Brazil and Paraguay.

**ECHINOCACTUS** (fig. 3) is the genus bearing the popular name of hedgehog cactus. It comprises nine species, native of the south-

western United States and Mexico. They have the fleshy stems characteristic of the family, these being either globose, oblong or cylindrical, and ribbed as in *Melocactus*, and armed with stiff sharp spines, set in little woolly cushions occupying the place of the buds. The flowers, produced near the top of the plant, are large and showy, yellow and rose being the prevailing colours. They are succeeded by succulent fruits, which are exserted, and scaly, in which respects this genus differs from *Melocactus* which has the fruits partly immersed and smooth. One of the most interesting species is *E. ingens*, in which there are 40 to 50 ridges, on which the buds and clusters of spines are sunk at intervals, the aggregate number of the spines having been in some cases computed at 50,000 on one plant. There are 27 related genera.

FIG. 3.—HEDGEHOG CACTUS (*ECHINOCACTUS HEXAEDROPHORUS*) COMMON IN THE DESERTS OF NORTH AND SOUTH AMERICA

**CEREUS**.—This genus bears the common name of torch thistle. It comprises about 25 species, largely Mexican but scattered through South America and the West Indies. The stems are columnar or elongated, some of the latter creeping on the ground. There are many related genera. *Carnegiea gigantea*, the largest of all cacti, is a native to hot, arid, desert regions of the southwestern United States, growing in rocky valleys and on mountain sides. The stems grow to a height of 70 ft. and have a diameter of 2 ft. often unbranched, but sometimes furnished with branches which grow out at right angles from the main stem, and then curve upwards and continue their growth parallel to it; these stems have from 12 to 20 ribs, on which, near the top at intervals of about an inch, are the buds with their thick, yellow cushions, from which issue five or six large and numerous smaller spines. The fruits, which are green oval bodies from 2 to 3 in. long, contain a crimson pulp from which the Indians prepare an excellent preserve; they also use the ripe fruit as food, gathering it with a forked stick attached to a long pole. Relatives of *Cereus* include some of our most interesting and beautiful hothouse plants. *Echinocereus pectinatus* produces a purplish fruit resembling a

gooseberry, which is very good eating; and the fleshy part of the stem itself is eaten as a vegetable after removing the spines. The climbing night-blooming cacti are included in the genera *Hylocereus*, *Selenicereus* and others, many bearing very large flowers.

**EPIPHYLLUM** and **PHYLLOCACTUS** (fig. 4), the leaf cactus, comprises 17 species, found in Mexico and Central and tropical South America. They differ from all the forms already noticed in being

FIG. 4.—BRANCH OF THE LEAF CACTUS, AN ORNAMENTAL PLANT POPULAR IN GARDEN CULTURE. THE FLOWERS ARE 6 IN. OR MORE IN DIAMETER

epiphytal in habit, and in having the branches compressed and dilated so as to resemble thick fleshy leaves, with a strong median axis and woody base. The margins of these leaf-like branches are crenately notched, the notches representing buds, and from these crenatures the large showy flowers are produced. As garden plants these are amongst the most ornamental of the family, being of easy culture, free blooming and showy, the colour of the flowers ranging from rose-pink to creamy white. Relatives of *Epiphyllum* compose 8 other genera.

**OPUNTIA**, the prickly pear or Indian cactus, is a large group, comprising some 250 species, or more, found in North America, the West Indies and South America, extending as far as Chile. Some have been introduced into Australia with disastrous effects, since they have overrun large tracts of country. They are fleshy shrubs with rounded, woody stems and numerous succulent branches, composed in most of the species of separate joints or parts, which are often much compressed, elliptic or suborbicular, dotted over in spiral lines with small, fleshy, caducous leaves, in the axils of which are the areoles or tufts of barbed or hooked bristles, usually accompanied by spines. The flowers are mostly yellow or reddish yellow, and are succeeded by pear-shaped or egg-shaped fruits, having a broad scar at the top, mostly furnished on their soft, fleshy rind with tufts of small bristles. The sweet, juicy fruits of several species are much eaten under the name of prickly pears, and these are cultivated for their fruit in Southern Europe, the Canaries and northern Africa.

The cochineal insect (*q.v.*) is nurtured on the allied *Nopalea coccinellifera* and sometimes also on species of *Opuntia*. Planta-

FIG. 5.—ORGAN CACTUS IN THE DESERT SOUTH OF MEXICO CITY

PAINTED FOR THE ENCYCLOPÆDIA BRITANNICA BY ISABEL COOPER AFTER SPECIMENS IN THE NEW YORK BOTANICAL GARDEN

## COMPOSITE GROUP OF CACTUSES OF NORTH AND SOUTH AMERICA

1. *Cereus Maynardae*, Viscountess Maynard's great-flowering *Cereus*, a hybrid between *Selenicereus grandiflorus*, of the West Indies, and *Heliocereus speciosus*, of Mexico. 2. *Opuntia*, probably *Opuntia vulgaris*, one of the prickly pears of south-eastern South America. 3. *Opuntia basilaris*, a spineless prickly pear, of the south-western United States and northern Mexico. 4.

*Echinocereus* sp., of the western United States and northern Mexico. 5. *Hickenia microsperma*, Professor Hicken's cactus, a native of northern Argentina. 6. *Lobivia cinnabarina*, Cinnabar cactus, found in the Andes of Bolivia. 7. *Cleistocactus smaragdiflorus*, a slender-flowered cactus, native of Argentina.

tions, called nopales, are established for rearing this insect, *Coccus cacti*, and these often contain as many as 50,000 plants. Relatives of *Opuntia* form 6 other genera.

**PERESKIA** differs from the rest in having woody stems and leaf-bearing branches, the leaves being somewhat fleshy, but otherwise of the ordinary laminate character. One species, the Barbadoes gooseberry, climbs like the blackberry (*Rubus*) by recurved thorns; the others are spiny shrubs. The flowers are subpaniculate, white or yellowish. They are frequently used as a stock on which to graft other *Cacti*. There are about 19 species, mainly Mexican; *P. cubensis* is a peculiar little tree of eastern Cuba.

**CADALSO VAZQUEZ, JOSE** (1741–1782), Spanish author, born at Cadiz, entered the army and rose to the rank of colonel. He was killed at the siege of Gibraltar. Cadalso was educated in Paris, travelled widely in his youth, and spread the knowledge of French and English literature in Spain. His first published work was a rhymed tragedy, *Don Sancho Garcia, Conde de Castilla* (1771), constructed on French classical lines. His *Eruditos à la Violeta* (1772) is a prose satire on superficial knowledge. In 1773 appeared a volume of miscellaneous poems, *Ocios de mi juventud*, and after his death there was found among his mss. a series of fictitious letters in the style of the *Lettres Persanes*, which were issued in 1793 under the title of *Cartas marruecas*. His collected works appeared at Madrid in 1821, and have been supplemented by the *Obras inéditas* (Paris, 1894) published by R. Foulché-Delbosc.

**CADAMOSTO or CA DA MOSTO, ALVISE** (1432–1477), a Venetian explorer, navigator and writer, celebrated for his voyages in the Portuguese service to West Africa. In 1454 he sailed from Venice for Flanders and being detained by contrary winds off Cape St. Vincent, was enlisted by Prince Henry the Navigator among his explorers, and given command of an expedition which sailed (on March 22, 1455) for the south. He wrote an account of his voyage, *El libro de la prima navigazione per l'oceano a le terre de Nigri*, printed in 1507. Visiting the Madeira group and the Canary islands, and coasting the West Sahara, he arrived at the Senegal, whose lower course had already, as he tells us, been explored by the Portuguese 60m. up. The negro lands and tribes south of the Senegal, and especially the country and people of Budomel, a friendly chief reigning about 50m. beyond the river, are next dealt with, and Cadamosto thence proceeded towards the Gambia, which he ascended some distance, but he found the natives extremely hostile, and so returned direct to Portugal. Throughout his account he provides a wealth of interesting detail about the tribes he met, their customs and their trade. Cadamosto expressly refers to the chart he kept of this voyage. At the mouth of the Gambia he records an observation of the "Southern Chariot" (Southern Cross). Next year (1456) he went out again under the patronage of Prince Henry. Doubling Cape Blanco he was driven out to sea by contrary winds, and thus made the first known discovery of the Cape Verde islands. Having explored Boavista and Santiago, and found them uninhabited, he returned to the African mainland, and pushed on to the Gambia, Rio Grande and Geba. Returning thence to Portugal, he seems to have remained there till 1463, when he reappeared at Venice.

Besides the accounts of his two voyages, Cadamosto left a narrative of Pedro de Cintra's explorations in 1461 (or 1462) to Sierra Leone and beyond Cape Mesurado to El Mina and the Gold Coast; all these relations first appeared in the 1507 Vicenza Collection of Voyages and Travels (the *Paesi nuovamente ritrovati et novo mondo da Alberico Vesputio Florentino*); they have frequently since been reprinted and translated (e.g., Ital. text in 1508, 1512, 1519, 1521, 1550 (Ramusio), etc. See also C. Schefer, *Relation des voyages... de Ca' da Mosto* (1895); R. H. Major, *Henry the Navigator* (1868), pp. 246–287; C. R. Beazley, *Henry the Navigator* (1895), pp. 261–288, and *Dawn of Modern Geography* (3 vols., 1897–1906); Yule Oldham, *Discovery of the Cape Verde Islands* (1892), especially pp. 4–15.

**CADASTRE**, a register of the real property of a country, with details of the area, the owners, and the value. A "cadastral survey" is properly, therefore, one which gives such information

as the Domesday Book, but the term is sometimes used loosely of the Ordnance Survey of the British Isles, which is on sufficiently large a scale to give the area of every field or piece of ground.

**CADBURY, GEORGE** (1839–1922), British manufacturer and philanthropist, was born Sept. 19, 1839 at Edgbaston, Birmingham, of Quaker parents, and was brought up a member of the Society of Friends. In 1861, when he succeeded to his father's business, it gave employment to 12 workers only, but under the management of himself and his brother Richard (1835–99) it developed rapidly, and in 1879 he founded for the employees the garden village of Bournville, which served as a model for other social ventures of this kind. He became chief proprietor of *The Daily News* (London) in 1901, and his family acquired an interest in *The Star* (London) in 1909. He died Oct. 24, 1922. See A. G. Gardiner *Life of George Cadbury* (1923).

**CADDIS-FLY** and **CADDIS-WORM**, the name given to insects with a superficial resemblance to moths and referred to the order Trichoptera (*q.v.*) in allusion to the hairy covering of the body and wings. Caddis-flies occur in the neighbourhood of fresh water in which they lay their eggs, and their larvae (caddis-worms) are aquatic. These larvae provide themselves with shelters (caddis-cases) made of particles of sand, sticks, leaves, etc., held together with silk which is secreted by the insects for that purpose. Should other materials be lacking, they will make their cases of glass beads. Thus concealed they crawl about seeking their food which is mainly of a vegetable nature. Before turning to the pupa the larva closes the orifice of the case against intruders, and the pupa when mature, after biting its way out, rises to the surface of the water to allow of the emergence of the perfect insect.

**CADDO**. A tribe, a confederacy and a stock of American Indians west of the Mississippi river are known by this name. The Caddoan stock occupied three territories. The largest, that of the Caddo or Hasinai confederacy and their kinsmen, embraced most of the drainage of Red River plus adjacent streams, in Louisiana, Arkansas, Oklahoma and Texas. The second, in Kansas and Nebraska, and the third, on the Missouri in the Dakotas, held respectively the Pawnee and Arikara (*q.v.*). The surviving tribes or bands of the first division are the Caddo, Wichita, Kichai, Tawakoni, Waco, reduced to less than 1,000 all told. Tribes now extinct or merged were the Anadarko, Hainai, Nacogdoches, Natchitoches, Yatasi. The Caddoan groups were agricultural and lived in villages of thatched houses. In general customs they were intermediate between the settled tribes of the lower Mississippi and Gulf states and the moving bison hunters of the Plains. They became known to the Spaniards and French in the 17th century, and the usual reduction in numbers soon followed contacts.

**CADE, JOHN** (d. 1450), commonly called JACK CADE, captain of Kent and leader of the rising of 1450, may have been an Irishman by birth, but details of his early life are scanty. After his death the Government asserted that he had lived in Sussex, had had to flee after murdering a woman, that he had served in the French wars and settled in Kent under the false name of Aylmer or Aylesmere. How much, if any of this can be believed, is unknown. Cade himself claimed the name Mortimer; he was a man of some landed property and importance, and may quite possibly have been a distant or illegitimate relation of the duke of York. The men of Kent, when they rose in rebellion in May 1450, selected him as their leader, and under his skilled direction marched from Ashford to Blackheath, retreated, defeated the king's supporters at Sevenoaks (June 18) and returned victoriously to London, which they entered on July 3. At this time Cade was at the height of his fortunes: his army was estimated at 40,000 men, and was certainly superior to the royal forces, and the city was favourable to his complaint of maladministration, waste, corruption, and oppression, and his opposition to the Statute of Labourers. Cade executed Lord Say-and-Sele and William Crowmer, sheriff of Kent; but his attempt to exact forced contributions led to the city gates being closed against him on the withdrawal of his army to Southwark (July 5). The Government now offered concessions and pardons, through the intermediary of Chancellor Kemp, which the Kentishmen accepted, and dispersed.

Cade's pardon was in the name of Mortimer; it was consequently declared invalid, and Cade himself was hunted down with his remaining followers by Alexander Iden, the new sheriff of Kent, and killed near Heathfield (July 13). Acts were afterwards issued attainting him and annulling all measures taken during his short predominance.

Stevenson, 1864); *An English Chronicle of the Reigns of Richard II., Henry IV., Henry V. and Henry VI.* (edit. by J. S. Davies 1856); *Historical Collections of a Citizen of London* (edit. by J. Gairdner, 1876); *Three Fifteenth Century Chronicles*, (edit. by J. Gairdner, 1880); G. Kriehn, *The English Rising of 1450* (Strasbourg, 1892); J. Gairdner, *Introduction to the Paston Letters* (1904); J. Clayton, *The True Story of Jack Cade* (1909).

**CADENABBIA**, a village of Lombardy, Italy, in the province of Como, 15m. N.N.E. by steamer from Como, on the west shore of the lake of Como, and a favourite spring and autumn resort. The Villa Carlotta, formerly the property of the duke of Saxe-Meiningen, now belonging to the Italian Government, contains marble reliefs by Thorwaldsen, representing the triumph of Alexander, and statues by Canova.

**CADENCE**, a falling or sinking, especially as applied to rhythmical or musical sounds, as in the "fall" of the voice in speaking, the rhythm or measure of verses, song or dance. In music, the word is used of the closing chords of a musical phrase, which succeed one another in such a way as to produce, first a sense of expectation or suspense, and then an impression of finality. "Cadenza," the Italian form of the same word, is used of a free flourish in a vocal or instrumental composition, introduced immediately before the close of a movement or at the end of the piece. The object is to display the performer's technique, or to prevent too abrupt a contrast between two movements. Cadenzas were formerly left to the improvisation of the performer, but nowadays usually are written by the composer, or by some famous executant like Joseph Joachim who wrote the cadenza in Brahms's *violin concerto*.

**CADER IDRIS** ("the chair of Idris"), one of the highest mountains in North Wales, ranking next to Snowdon in popular favour. It stands south of Dolgelley and the Mawddach estuary, in Merionethshire. The main core is formed by a bare ridge some 8m. long, culminating in Pen-y-Gader (2,927ft.) and sharply defined by steep rock-walls, nearly 1,000ft. in height, to the north. The southward slopes to the Dysynni valley are grass-grown but abrupt, while the sheer drop from the knife-edge ridge to the dark tarn of Llyn-y-Cau backs one of the most remarkable cirques (*cwm*s) of Britain. Beyond the narrow wall, 1,000–1,200ft. in height, in the opposing cwm, lies Llyn-y-Gader. The views from the summit are specially rich and varied on the north side; to the south-west the wide sweep of Cardigan bay is embraced. Mention of Cader Idris and its legends is frequent in Welsh literature, old and modern.

**CADET**, the head of a junior branch of a family, a younger son (through the Fr. from the late Lat. *capitellum*, a diminutive of *caput*, head, through the Provençal form *capdet*). Employed as a military term for an accepted candidate for a commission in the army or navy, who is undergoing training to become an officer. This latter use of the term arose in France, where it was applied to the younger sons of the *noblesse* who gained commissioned rank, not by serving in the ranks or by entering the *écoles militaires*, but by becoming attached to corps without pay but with certain privileges. "Cadet Corps," in the British service, are bodies of boys or youths organized, armed and trained on volunteer military lines. Derived from "cadet," through the Scots form "cadee," comes "caddie," a messenger-boy, and particularly one who carries clubs at golf, and also the slang word "cad," a vulgar, ill-bred person.

**CADI** (*qādī*), a judge in a Muhammadan court, in which decisions are rendered on the basis of the canon law of Islam (*sharī'a*). It is a general duty, according to canon law, upon a Muslim community to judge legal disputes on this basis, and it is an individual duty upon the ruler of the community to appoint a

cadi to act for the community. According to Shāfi'ite law, such a cadi must be a male, free, adult Muslim, intelligent, of unassailed character, able to see, hear and write, learned in the Qur'ān, the traditions, the Agreement, the differences of the legal schools, acquainted with Arabic grammar and the exegesis of the Qur'ān. He must not sit in a mosque, except under necessity, but in some open, accessible place. He must maintain a strictly impartial attitude of body and mind, accept no presents from the people of his district, and render judgment only when he is in a normal condition mentally and physically. He may not engage in any business. On some of these points the codes differ, and the whole is to be regarded as the ideal qualification, built up theoretically by the canonists.

See Th. W. Juynboll, *Handbuch des islamischen Gesetzes* (1910); E. Sachau, *Muhammedanisches Recht* (1897).

**CADILLAC** (*kādī-lāḳ*), a city of Michigan, U.S.A., 95m. N. of Grand Rapids, on Lakes Cadillac and Mitchell, which are connected by a picturesque canal 200yd. long; the county seat of Wexford county. It is on Federal highway 131, and is served by the Ann Arbor and the Pennsylvania railways. The population in 1930 was 9,570. It is the supply and shipping centre for a lumbering and farming region, and has large lumber mills, woodworking factories and other industries. There is good fishing in the lakes and streams. Many unusual Indian relics are found in this region, and there are prehistoric earthworks near the city. Cadillac was settled in 1871, and in 1877 was chartered as a city under its present name (after Antoine de la Mothe Cadillac). It has a commission-manager form of government.

**CADIZ**, a province of southern Spain, formed in 1833 of districts taken from Seville. It is bounded on the north by Seville, east by Málaga, south-east by the Mediterranean sea, south by the Strait of Gibraltar, and west by the Atlantic ocean. Pop. (1920) 547,827; area, 2,834 sq.m.; inclusive, in each case, of Ceuta, on the Moroccan coast, which, for administrative coastline of Cadiz are the broad Guadalquivir estuary which marks the frontier of Seville, the magnificent double bay of Cadiz, outlet for the Guadalete, chief river of the north districts, and Cape Trafalgar, famous for the British naval victory of 1805. Farther south, the river Barbate draining the broad, marshy Laguna de la Janda, flows into the Strait of Gibraltar and Punta Marroqui, on the strait, is the southernmost promontory of the European mainland. On the east coast the rock and fortress of Gibraltar overlook Algeciras bay and the river Guadiaro, which drains the eastern highlands, enters the Mediterranean close to the frontier of Málaga. In the interior there is a striking contrast between the comparatively level western half of the province and the picturesque well-wooded mountain ranges of the east. These mountains, which form the west end of the Boetic Cordillera, attain their greatest altitudes in the Cerro de San Cristobal (5,630ft.) and the Sierra del Pinar (5,413ft.).

The climate is mild and equable, and with naturally fertile soil makes fruit, vine and olive growing one of the chief sources of wealth in the province, though severe droughts often cause great distress. Jerez de la Frontera (Xeres) is famous for the manufacture and export of sherry, and Tarifa for its oranges. Much cork is obtained from the mountain forests, and quantities of fish are caught off the coast and are salted for export. A considerable amount of salt is obtained by evaporation of seawater in pans near Cadiz bay. In 1924 the province produced over 300,000 tons of salt, over one-third of the total Spanish output. Railway communication is limited in the west to a line from Seville to Cadiz, with branch lines to Sanlúcar from Jerez and Puerto de Santa Maria, and from Sanlúcar a few miles north to Bonanza; and in the east to a line from Granada to Algeciras.

The principal towns are Cadiz, pop. (1920), 76,718; La Línea (63,236); Sanlúcar (27,103); the naval station of San Fernando (26,953); Algeciras (19,417); Puerto de Santa Maria (18,839); Tarifa (11,957) and Puerto Real (9,198) on the coast; Jerez de la Frontera (64,861); Arcos de la Frontera (15,748); Vejer de la Frontera (14,995); Medina-Sidonia (13,416) and Chiclana (12,009) inland. These are described in separate articles. Olvera (11,183), San Roque (10,903), Jimena de la Frontera (9,342)

and Grazalema, probably the Roman *Lacidulermium* (4,298) are lesser towns trading in farm produce, wine and leather. (See also *ANDALUSIA*.)

**CADIZ**, capital and principal seaport of the Spanish province described above; on Cadiz bay, an inlet of the Atlantic ocean; 94m. by rail south of Seville. Pop. (1920) 76,718. Cadiz is built on the low, rocky extremity of a narrow, sandy spit projecting about 5m. into the sea, in a north to west direction from the *Isla de Leon*, which is separated from the mainland by a broad channel known as the *Rio Santi Petri*. The isthmus and headlands on the mainland to the north nearly enclose the splendid bay, over 30m. in circuit, to which Cadiz owes its commercial importance. The outer bay, affording extensive anchorage in from 6 to 10 fathoms of water, stretches from the promontory of Rota to the mouth of the *Rio de San Pedro*, a distributary of the *Guadalete* which enters the bay opposite Cadiz. The inner bay, guarded at its narrow entrance by the forts of *Puntales* and *Cortadura* on the isthmus, also provides good anchorage, though in rather shallower water. On its south shore is the important naval arsenal of *San Fernando*. The entrance to the bays is somewhat obstructed by low shelving rocks (*Los Cochinos* and *Las Puercas*) and by shifting mud banks deposited by the rivers, but the channel is well marked by illuminated buoys.

Owing to its almost insular position Cadiz enjoys a mild climate, with temperatures seldom falling below 53° F. in winter or rising above 76° F. in summer. Winter is, however, the pleasanter season, as in summer the heat is either glaring, if land winds prevail, or very oppressive when the moisture-laden *W. Virazón* sets in.

The city, only 6 to 7m. in circumference, is peculiarly restricted by its position, being practically hemmed in by the sea and surrounded by a wall, now largely demolished, round the harbour on the east, but with only one land exit, a gate communicating with the isthmus. In view of the uniformity and elegance of its buildings, Cadiz must certainly be ranked as one of the finest cities of Spain. The houses, three-storied or more high, have flat roofs and watch towers in the Moorish style. The marine promenades which fringe the city between the ramparts and the sea are very fine, especially that called the *Alameda*, on the eastern side overlooking the bay. The general air of cleanliness, due partly to the fact that the houses are whitewashed every year, is, however, deceptive, as the drainage of the low-lying city is quite inadequate and refuse, thrown over the sea-walls, collects in heaps along the shore. The water-supply is also bad. The water, apart from that collected in cisterns from the roofs, is brought at great expense from *Santa Maria* on the opposite coast by an aqueduct nearly 30m. long. The city possesses only one fresh water spring, which rises under the high altar of the old cathedral. Several times in its history its population has been decimated by disease, but the death-rate has gradually decreased since the beginning of the 20th century.

Cadiz is the see of a bishop, who is suffragan to the archbishop of Seville. The old cathedral, originally erected by *Alphonso X.* of Castile (1252-84) and rebuilt after 1596, is now only a church. The new cathedral, begun in 1722 and completed between 1832 and 1838, is chiefly remarkable for its yellow dome and vast crypt. The church of *Santa Catalina*, formerly attached to a Capuchin convent which is now secularized and used as a lunatic asylum, contains an unfinished picture of the marriage of *St. Catherine*, by *Murillo*, who met his death by falling from the scaffold on which he was painting it (April 3, 1682). In the centre of the town there is a watch-tower, the *Torre Vigía*, from which the arrival and departure of vessels are signalled. Cadiz possesses three theatres and a bull-ring, accommodating 11,500 spectators, and many charitable institutions, such as the large *Hospico de Misericordia*, the *Hospico* for men, the women's hospital and the founding institution. There are many free schools and several mathematical and commercial academies, a nautical school, a school of design, a theological seminary and a flourishing medical school attached to the *University of Seville*. The archaeological museum contains numerous Roman and Carthaginian relics and the academy possesses a valuable collection of pictures. Most of the old fortifications have been demolished but there is a fort as well as

a lighthouse on the rock of *San Sebastian* to the west of the city. Modern villas and bathing establishments are growing up along the isthmus.

Cadiz, in spite of its fine natural harbour and splendid geographical position, no longer ranks among the first marine cities of the world. The loss of the Spanish colonies in America, early in the 19th century following the Napoleonic wars, dealt a blow to its trade from which it has never recovered. Its decline was later accelerated by the disasters of the Spanish-American war of 1898, which almost ruined local commerce with Cuba and Porto Rico and by the decreasing demand for sherry, but above all by the lack of enterprise among its citizens, who allowed its harbour works to become out of date. Since the beginning of the 20th century, however, considerable improvements have been made. Moles, wharves and warehouses have been constructed and the present harbour has over 2m. of quayage. A free depot established in 1823, but lapsing since 1832, has been successfully revived on modern lines. Industrial development is small but important naval and mercantile shipbuilding yards and various factories exist on the mainland and there are tunny fisheries off the coast. The city is above all a commercial port, exporting much wine, principally sherry from *Jerez*, salt, olives, figs, corks and salted fish, and importing coal, iron and machinery, timber, cereals, coffee and other foodstuffs. Several great shipping lines call at Cadiz and passenger traffic is important. In 1926, 2,054 ships of all kinds, with a total tonnage of 2,152,349, entered the port. In spite of modern improvements, however, the development of Cadiz must always be checked by the restrictions of its site and by its limited access to and from the mainland along the narrow isthmus. This accommodates only one road, a railway and an electric tram-line, connecting Cadiz with *San Fernando*. Modern rivalry with Seville has also caused a loss of local trade.

**History.**—Cadiz, founded, according to tradition, by Phoenician merchants from Tyre as early as 1100 B.C., had become by the 7th century the great western market for the amber and tin from the *Cassiterides* (q.v.). About 501 B.C. it was occupied by the Carthaginians, who in the 3rd century made it their base for the equipment of the armaments with which Hannibal undertook to destroy the power of Rome. At the close of the Second Punic War the city willingly surrendered to Rome and from this time its prosperity steadily increased. Its growing trade in dried fish and meat, and in all the produce of the fertile *Baetis* (*Guadalquivir*) valley, attracted many Greek settlers; while men of learning, such as *Pytheas* in the 4th century B.C., *Polybius* and *Artemidorus* of Ephesus in the 2nd, and *Posidonius* in the 1st, came to study its tides, unparalleled in the Mediterranean. C. *Julius Caesar* conferred the *civitas* of Rome on all its citizens in 49 B.C.; and L. *Cornelius Balbus Minor* built what was called the "New City," the harbour now known as *Puerto Real*, and the bridge still existing across the *Rio Santi Petri*. The wealth and importance of *Gades* was so great at this period that under *Augustus* it was the residence of no fewer than 500 *equites*, and was made a *municipium* with the name of *Augusta Urbs Gadihana*, with citizenship ranking next to that of Rome. *Juvenal* and *Martial* write of *Jocosae Gades*, "Cadiz the Joyous"; and throughout the Roman world its cookery and its dancing-girls were famous. In the 5th century, however, the overthrow of Roman dominion in Spain by the Visigoths involved Cadiz in destruction. A few fragments of masonry, submerged under the sea, are almost all that remains of the original city. Moorish rule over the port, which was renamed *Jezirat-Kadis*, lasted from 711 until 1262, when Cadiz was captured, rebuilt and repopled by *Alphonso X.* of Castile. Its renewed prosperity dates from the discovery of America in 1492. As the headquarters of the Spanish treasure fleets, it soon recovered its position as the wealthiest port of western Europe, and consequently it was a favourite point of attack for the enemies of Spain. During the 16th century it repelled a series of raids by the Barbary corsairs; in 1587 all the shipping in its harbour was burned by the English squadron under *Sir Francis Drake*; in 1596 the fleet of the earl of *Essex* and *Lord Charles Howard* sacked the city, and destroyed 40 merchant vessels and 13 warships. This disaster necessitated the rebuilding of Cadiz on a new plan, but it quickly recovered, and its

new fortifications enabled it to repel successfully attacks by British fleets under the duke of Buckingham in 1626, Admiral Blake in 1656 and Sir George Rooke and the duke of Ormonde in 1702. During the 18th century the wealth of Cadiz became greater than ever; from 1720 to 1765, when it enjoyed a monopoly of the trade with Spanish America, the city annually imported gold and silver to the value of about £5,000,000. Its wealth at this time is said to have been greater than that of London. With the closing years of the century, however, it entered upon a period of misfortune. From February 1797 to April 1798 it was blockaded by the British fleet, and in 1800 it was bombarded by Nelson. In 1808 the citizens captured a French squadron which was imprisoned by the British fleet in the inner bay. From February 1810 until relieved by the duke of Wellington in Aug. 1812, Cadiz was besieged by French forces, during which time it served as the capital of all Spain which could escape annexation by Napoleon. Here, too, the Cortes met and promulgated the famous Liberal constitution of March 1812. To secure a renewal of this constitution the citizens revolted in 1820. The revolution spread throughout Spain. The king, Ferdinand VII., was imprisoned at Cadiz but was released by a French army which seized Cadiz in 1823 and suppressed Liberalism throughout the country.

See *Sevilla y Cadiz, sus monumentos y artes, su naturaleza é historia*, an illustrated volume in the series "España," by P. de Madrazo (Barcelona, 1884); *Recuerdos Gaditanos*, a very full history of local affairs, by J. M. León y Domínguez (Cadiz, 1897); *Historia de Cadiz y de su provincia desde los remotos tiempos hasta 1824*, by A. de Castro (Cadiz, 1858); and *Descripción historico-artística de la catedral de Cadiz*, by J. de Urrutia (Cadiz, 1843).

**CADIZ**, a municipality (with administration centre and 10 barrios or districts) of the province of Occidental Negros, island of Negros, Philippine Islands, on the north coast, about 53 m. N.N.E. of Bacolod, the provincial capital. Pop. (1918) 21,260, of whom only 15 were whites. In 1918 it had eight manufacturing establishments with output valued at 464,200 pesos, 38 sugar-mills, with output valued at 512,800 pesos, and 77 household industry establishments, with output valued at 19,300 pesos. Of the 11 schools, eight were public. The language spoken is a dialect of Bisayan.

**CADMAN, CHARLES WAKEFIELD** (1881- ), American musical composer, was born at Johnstown (Pa.), on Dec. 24, 1881. He used American-Indian material in music. His song, "From the Land of Skyblue Water," has become a classic of American song literature in many countries, including Russia. Among his operas are *Shanewis* (The Robin Woman), produced at the Metropolitan Opera House on March 23, 1918, and repeated in 1919, the first American opera to live beyond a season; *The Garden of Mystery* produced in New York, March 18, 1925; and *A Witch of Salem*, produced by the Chicago Opera Company, Dec. 8, 1926. Other compositions include a cantata, *The Vision of Sir Launfal*; a piano sonata; a trio and many songs.

**CADMAN, SAMUEL PARKES** (1864- ), American clergyman, author and lecturer, was born in Wellington, Shropshire, England, on Dec. 18, 1864. He graduated with honours from Richmond college, Surrey, in 1889. In 1890 he went to the United States and in 1895 was appointed the leader of the forward movement in New York City Methodism. In 1901 he was called to the pastorate of the Central Congregational Church of Brooklyn. He was elected president of the Federal Council of Churches of Christ in America in 1924, and in 1928 was chosen by this council and the National Broadcasting Company of America as their official radio preacher.

He is the author of *William Owen, A Biography* (1910); *The Religious Uses of Memory* (1911); *Charles Darwin and other English Thinkers* (1911); *The Three Religious Leaders of Oxford* (1916); *Ambassadors of God* (1920); *Christianity and The State* (1924); *Imagination and Religion* (1926); and *Pro Christo* (1928).

**CADMIUM**, a metallic element, showing a close relationship to zinc, with which it is very frequently associated; (symbol Cd, atomic number 48, atomic weight 112.41, isotopes 114, 112, 110, 113, 111, 116). It was discovered in 1817 by F. Stromeyer in a sample of zinc carbonate yielding a yellow zinc oxide, although quite free from iron. Simultaneously Hermann discovered the new metal in a specimen of zinc oxide which had been thought to con-

tain arsenic, since it gave a yellow sulphide in acid solution on the addition of sulphuretted hydrogen.

Cadmium does not occur naturally in the uncombined condition, and only one mineral is known which contains it in any appreciable quantity, namely, greenockite or cadmium sulphide, found at Greenock and at Bishopton in Scotland, and in Bohemia and Pennsylvania. It is, however, nearly always found associated with zinc blende, and with calamine, although only in small quantities rarely exceeding 3%.

The metal is usually obtained from the flue-dust (produced during the first three or four hours' working of a zinc distillation) which is collected in the sheet iron cones or adapters of the zinc retorts. This is mixed with small coal, and when redistilled gives an enriched dust, and by repeating the process and distilling from cast iron retorts the metal is obtained. It can be purified by solution in hydrochloric acid and subsequent precipitation by metallic zinc. This process is repeated and finally the cadmium is deposited by electrolysis.

Cadmium is a white metal, possessing a bluish tinge, and is capable of taking a high polish; on breaking, it shows a distinct fibrous fracture. By sublimation in a current of hydrogen it can be crystallized in the form of regular octahedra; it is slightly harder than tin but is softer than zinc, and, like tin emits a crackling sound when bent. It is malleable and can be rolled out into sheets. The specific gravity of the metal is 8.564, this value being slightly increased after hammering; its specific heat is 0.0548, it melts at 322° C. and boils at 778° C., forming a deep yellow vapour. The cadmium molecule, as shown by determinations of the density of its vapour, is monatomic. The metal unites with the majority of the heavy metals to form alloys; some of these, the so-called fusible alloys, find a useful application from the fact that they possess a low melting point. An alloy of lead with 10% of cadmium and 10% of tin forms a solder. It also forms amalgams with mercury, and on this account has been employed in dentistry for the purpose of stopping (or filling) teeth. The metal is quite permanent in dry air, but in moist air it becomes coated with a superficial layer of the oxide; it burns on heating to redness, forming a brown coloured oxide; and is readily soluble in mineral acids with formation of the corresponding salts. Cadmium decomposes water vapour at a red heat, with liberations of hydrogen and formation of the oxide of the metal.

Cadmium oxide, CdO, is a brown powder of specific gravity 6.5, which can be prepared by heating the metal in air or in oxygen, or by ignition of the nitrate or carbonate, or by heating the metal to a white heat in a current of oxygen, when it is obtained as a dark red crystalline sublimate. It does not melt at a white heat, and is easily reduced to the metal by heating in a current of hydrogen or with carbon. It is a basic oxide, dissolving readily in acids, with the formation of salts, somewhat analogous to those of zinc.

Cadmium hydroxide, Cd(OH)<sub>2</sub>, is obtained as a white precipitate by adding potassium hydroxide to a solution of any soluble cadmium salt. It is decomposed by heat into the oxide and water, and is soluble in ammonia but not in excess of dilute potassium hydroxide; the latter property serves to distinguish it from zinc hydroxide.

The chloride, CdCl<sub>2</sub>, bromide, CdBr<sub>2</sub>, and iodide, CdI<sub>2</sub>, are soluble salts; and cadmium iodide which is one of the few iodides which are soluble in alcohol, is sometimes used in photography. Cadmium chloride and iodide behave in an anomalous way in concentrated aqueous solution probably owing to the formation of complex ions Cd(CdI<sub>2</sub>)<sub>2</sub>; the abnormal behaviour diminishing as the solution becomes more dilute, until, at very high dilutions the salts are ionized in the normal manner.

Cadmium sulphate, CdSO<sub>4</sub>, is known in several hydrated forms, being deposited, on spontaneous evaporation of a concentrated aqueous solution, in the form of large monosymmetric crystals of composition 3CdSO<sub>4</sub>·8H<sub>2</sub>O, whilst a boiling saturated solution to which concentrated sulphuric acid has been added, deposits crystals of composition CdSO<sub>4</sub>·H<sub>2</sub>O. It is largely used for making standard electric cells, such for example as the Weston, which gives a practically constant voltage under normal conditions.

Cadmium sulphide, CdS, occurs naturally as greenockite (*g.v.*),

and can be artificially prepared by passing sulphuretted hydrogen through acid solutions of soluble cadmium salts, when it is precipitated as a pale yellow amorphous solid. It is used as a pigment (cadmium yellow), for it retains its colour in an atmosphere containing sulphuretted hydrogen; it melts at a white heat, and on cooling solidifies to a lemon-yellow micaceous mass.

An enamel pigment known as fine red or cadmium red is prepared from a mixture of 80–90% of cadmium sulphide and 10–20% of selenium. The well mixed components are heated at 700° C. The product corresponds in composition to  $\text{Cd}_3\text{Se}_2$ . In a wet process a mixture of soluble sulphides and selenides is added to a solution of cadmium salt and the precipitate is ignored.

Normal cadmium carbonate is unknown, a white precipitate of variable composition being obtained on the addition of solutions of the alkaline carbonates to soluble cadmium salts.

Cadmium nitrate,  $\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ , is a deliquescent salt, which may be obtained by dissolving either the metal, or its oxide or carbonate in dilute nitric acid. It crystallizes in needles and is soluble in alcohol. In the foregoing compounds cadmium is bivalent, although it differs from zinc and resembles mercury in exhibiting a tendency to become univalent in cadmous chloride,  $\text{CdCl}$ , and the corresponding hydroxide and oxide,  $\text{CdOH}$  and  $\text{Cd}_2\text{O}$ .

Cadmium salts can be recognized by the brown incrustation which is formed when they are heated on charcoal in the oxidizing flame of the blowpipe; and also by the yellow precipitate formed when sulphuretted hydrogen is passed through their acidified solutions. This precipitate is insoluble in cold dilute acids, in ammonium sulphide and in solutions of the caustic alkalis, a behaviour which distinguishes it from the yellow sulphides of arsenic and tin. Cadmium is estimated quantitatively by conversion into the oxide, being precipitated from boiling solutions by the addition of sodium carbonate, the precipitate thus formed passing into the oxide on ignition. It can also be determined as sulphide, by precipitation with sulphuretted hydrogen, the precipitated sulphide being dried at 100° C. and weighed.

**CADMUS**, son of Phoenix or Agenor, king of Phoenicia and brother of Europa. After his sister had been carried off by Zeus, he was sent out to find her. Unsuccessful in his search, he came to Delphi, where he consulted the oracle. He was ordered to give up his quest and follow a cow which would meet him, and to build a town on the spot where she would lie down. The cow met him in Phocis, and guided him to Boeotia, where he founded the city of Thebes. Intending to sacrifice the cow, he sent some of his companions to a neighbouring spring for water. They were slain by a dragon, which was in turn destroyed by Cadmus, and by the instructions of Athena he sowed its teeth in the ground, from which there sprang a race of fierce armed men, called Sparti (sown). By throwing a stone among them Cadmus caused them to fall upon each other till only five survived, who assisted him to build the Cadmeia or citadel of Thebes and became the founders of the noblest families of that city (Ovid, *Metam.* iii. i. ff.; Apollodorus iii.). Cadmus, however, because of this bloodshed, had to do penance for eight years. At the expiration of this period the gods gave him to wife Harmonia (*q.v.*), daughter of Ares and Aphrodite, by whom he had a son Polydorus, and four daughters, Ino, Autonoe, Agave and Semele. At the marriage all the gods were present; Harmonia received as bridal gifts a robe worked by Athena and a necklace made by Hephaestus. Cadmus is said to have finally retired with Harmonia to Illyria, where he and his wife were changed into snakes. The origin of this story is highly doubtful.

See O. Crusius in Roscher's *Lexikon* (bibliography).

**CADMUS OF MILETUS**, according to some ancient authorities, the inventor of history, or simply the author of certain letters of the Greek alphabet. Suidas mentions three writers so called, one being "later" and author of a history of Attica, among other works. He may be real; but, as Dionysius of Halicarnassus (*Judicium de Thucydide*, c. 23) distinctly states that the work current in his time under the name of Cadmus was

a forgery, it is most probable that the two first are identical with the Phoenician Cadmus, who, as the reputed inventor of letters, was subsequently transformed into the Milesian and the author of an historical work.

See C. W. Müller, *Frag. Hist. Graec.* ii. 2–4; and O. Crusius in Roscher's *Lexikon der Mythologie* (article "Kadmos," 90, 91).

**CADOGAN, WILLIAM CADOGAN**, 1st EARL (1675–1726), British soldier, was the son of Henry Cadogan, a Dublin barrister, and grandson of Major William Cadogan (1601–61), governor of Trim. The family has been credited with a descent from Cadwgan, the old Welsh prince. Cadogan began his military career as a cornet of horse under William III. at the Boyne, and, with the regiment now known as the 5th (Royal Irish) Lancers, made the campaigns in the Low Countries. In the course of these years he attracted the notice of Marlborough. In 1701 Cadogan was employed by him as a staff officer in the complicated task of concentrating the grand army formed by contingents from multitudinous states, and Marlborough soon made the young officer his confidential staff officer and right-hand man. His services in the campaign of 1701 were rewarded with the colonelcy of the famous "Cadogan's Horse" (now the 5th Dragoon Guards). As quartermaster general, he organized the celebrated march of the allies to the Danube. At the Schellenberg he was wounded and his horse shot under him, and at Blenheim he acted as Marlborough's chief of staff. Soon after he was promoted brigadier general, and in 1705 he led "Cadogan's Horse" at the forcing of the Brabant lines between Wange and Elissem, capturing four standards. He was present at Ramillies, and immediately afterwards was sent to take Antwerp, which he did without difficulty. Becoming major general in 1706, he continued to perform the numerous duties of chief staff officer, quartermaster general and colonel of cavalry, besides which he was throughout constantly employed in delicate diplomatic missions. In the course of the campaign of 1707, when leading a foraging expedition, he fell into the hands of the enemy but was soon exchanged. In 1708 he commanded the advanced guard of the army in the operations which culminated in the victory of Oudenarde, and in the same year he was with Webb at the action of Wynendael. On Jan. 1, 1709, he was made lieutenant general. He was present at Malplaquet, and after the battle was sent off to form the siege of Mons, at which he was dangerously wounded. At the end of the year he received the appointment of lieutenant of the Tower, but he continued with the army in Flanders to the end of the war. His loyalty to the fallen Marlborough cost him, in 1712, his rank, positions and emoluments under the Crown. George I. on his accession, however, reinstated Cadogan, and, amongst other appointments, made him lieutenant of the ordnance. In 1715, as British plenipotentiary, he signed the third Barrier Treaty between Great Britain, Holland and the emperor. His last campaign was the Jacobite insurrection of 1715–16. At first as Argyle's subordinate (see Coxe, *Memoirs of Marlborough*, ch. cxiv.), and later as commander-in-chief, General Cadogan by his firm, energetic and skilful handling of his task restored quiet and order in Scotland. Up to the death of Marlborough he was continually employed in diplomatic posts of special trust, and in 1718 he was made Earl Cadogan, Viscount Caversham and Baron Cadogan of Oakley. In 1722 he succeeded his old chief as head of the army and master general of the ordnance, becoming at the same time colonel of the 1st or Grenadier Guards. He sat in five successive parliaments as member for Woodstock. He died at Kensington in 1726.

As a soldier, Cadogan was one of the best staff officers in the annals of the British army, and in command of detachments, and also as a commander-in-chief, he showed himself to be an able, careful and withal dashing leader.

He was succeeded, by special remainder, in the barony by his brother, General Charles Cadogan (1691–1776), who married the daughter of Sir Hans Sloane, thus beginning the association of the family with Chelsea, and died in 1776, being succeeded in turn by his son Charles Sloane (1728–1807), who in the year 1800 was created Viscount Chelsea and Earl Cadogan. His descendant George Henry, 5th Earl Cadogan (1840–1915), was lord

privy seal from 1886 to 1892, and lord-lieutenant of Ireland from 1895 to 1902.

**CADORNA, LUIGI**, COUNT (1850-1928), Italian general, was born at Pallanza, Lake Maggiore, Sept. 4, 1850. His father was Count Raffaele Cadorna, a distinguished soldier of the wars of the Risorgimento and the Crimea. Luigi Cadorna entered the army in 1866, and served in the infantry, in the artillery and on the staff, becoming colonel in 1892. In 1905 he became lieutenant-general, and a year later was chosen as an army commander in the event of war. In the manoeuvres of 1911 he opposed Caneva, who as victor was given the command in Tripoli.

In 1914, however, on the death of Gen. Pollio, chief of the general staff, Cadorna was appointed to succeed him (July 10). He found the army in a deplorable condition, with regard to personnel and material; moreover, within three weeks, the outbreak of the World War forced the problems of army reform to the front. Though handicapped by lack of money and by Italy's low industrial capacity, in the interval between Aug., 1914 and the entry of Italy into the War Cadorna fashioned a weapon with which it was possible to strike, and to strike hard.

For 29 months, handicapped always by lack of means, Cadorna directed the operations against Austria-Hungary with insight, vigour and determination. Facile critics have found fault with his plan of campaign, but the more carefully and objectively this is studied, the more it justifies itself. For a year Cadorna had the full confidence of his country. The first check came with the initial success of the Austrian offensive in the Trentino-Asiago area in May, 1916. As time went on, and signs of war-weariness became visible among the troops, Cadorna entered the strongest protest against the policy of the Government, which, he said, permitted an anti-war propaganda which was detrimental to the morale of the army. Though these protests were largely justified, it must be admitted that a part of the responsibility for declining morale lay at Cadorna's own door, for he did not seem to have fully realized the strain of modern war upon the troops. The disaster of Caporetto led to the transfer of Cadorna in Nov., 1917, from the command of the Italian armies to the newly formed Allied Military Council at Versailles. But before leaving his command he had organized the defences on the Piave-Monte Grappa front, and thus had made a stout resistance possible.

Cadorna came to Versailles under the shadow of defeat, but his personality and military insight soon impressed his colleagues and removed the initial handicap. It was a misfortune for Italy when, in Feb., 1918, consequent upon the appointment of the Caporetto inquiry commission, it was thought necessary to remove him from Versailles. As a result of the inquiry he was placed on half-pay on Aug. 29, 1918, and four days later his definite retirement was gazetted. General Cadorna died on December 21, 1928.

In March 1921 Cadorna published a book dealing with his tenure of the post of chief of staff (*La Guerra alla Fronte Italiana*), which effectively answered much of the criticism that had been directed against his leadership. This work was followed by *Altre Pagine sulla Grande Guerra* (1925). On the sixth anniversary of the Italian victory (Nov. 4, 1924), the newly created rank of marshal was conferred on him. Cadorna has literary gifts and among his writings is *Il Generale Raffaele Cadorna nel Risorgimento Italiano* (1922).

**CADOUDAL, GEORGES** (1771-1804), leader of the *Chouans* during the French Revolution, was born on Jan. 1, 1771, near Auray (Morbihan). From 1793 he organized a revolt in the Morbihan which was quickly suppressed, and he thereupon joined the army of the revolted Vendéans, taking part in the battles of Le Mans and of Savenay in December 1793. Returning to Morbihan, he was arrested, but escaped from his prison at Brest. Cadoudal was one of the leaders of the Chouannerie, and was constantly fomenting trouble in Brittany, escaping, when the position was dangerous, to England. After the repression of the revolt of 1800 he came to Paris and had an interview with Napoleon, but the police suspected him of a plot to murder the latter, and he fled again to England. In Aug. 1803 Cadoudal crossed the Channel for the last time, in a British cutter, armed with British Government drafts to finance a rising in Paris. On

Feb. 29, 1804, Pichegru was arrested, on March 9 Cadoudal, and shortly afterwards many others. The conspirators were said to be expecting a prince, and Napoleon's police imagined the prince to be the duc d'Enghien. Cadoudal and 19 of his companions were sentenced to death. Some of the sentences were commuted, but Cadoudal, with others, was executed on June 24. Cadoudal is popularly known as Georges.

See *Procès de Georges, Moreau et Pichegru* (1804); the *Mémoires* of Bourrienne, of Hyde de Neuville and of Rohu; Lenotre, *Tournebut* (on the arrest); Lejean, *Biographie bretonne*.

**CADRE**, a framework or skeleton, particularly the permanent establishment of a military corps, regiment, etc., which can be expanded on emergency. The modern tendency is for the cadre to be largely composed of commissioned and non-commissioned officers capable of filling higher grades on mobilization, and trained as instructors so that they may train the new recruits by intensive methods.

**CADUCEUS** (the Lat. adaptation of the Doric Gr. *καρῦκειον*, Attic *κηρύκειον*), a herald's wand, and hence the staff used by messengers. The caduceus of Hermes is a familiar example. In its oldest form it was a rod ending in two prongs (probably an olive branch with two shoots, adorned with ribbons or garlands), for which, later, two serpents, with heads meeting at the top, were substituted. A pair of wings was sometimes attached to the top of the staff. In historical times the caduceus was the attribute of Hermes as the god of commerce and peace, and among the Greeks it was the distinctive mark of heralds and ambassadors, whose persons it rendered inviolable. The caduceus itself was not used by the Romans, but the derivative *caduceator* occurs in the sense of a peace commissioner.

See F. J. M. Waele, *The Magic Staff or Rod in Graeco-Italian Antiquity* p. 29 et seq.

**CADUCOUS**, a botanical term for "falling early," applied, for example, to the sepals of a poppy which fall before the petals expand.

**CAECILIA, VIA**, an ancient highroad of Italy, which diverged from the Via Salaria at the 35th m. from Rome, and ran by Amiternum to Interamna Praetutiorum (Teramo) and thence to the sea at Castrum Novum (Giulianova), a distance of about 148m. from Rome. It was probably constructed by L. Caecilius Metellus Diadematus (consul in 117 B.C.).

See C. Hülsen in *Notizie degli Scavi*, 87 seq. (1896); N. Persichetti in *Römische Mitteilungen* (1898), 193 seq. (1902) 277 seq.

**CAECILIUS**, of Calacte in Sicily, Greek rhetorician, flourished at Rome during the reign of Augustus. Next to Dionysius of Halicarnassus, he was the most important critic and rhetorician of the Augustan age. Only fragments of his works are extant, among which may be mentioned: *On the Style of the Ten Orators* (including their lives and a critical examination of their works), the basis of the pseudo-Plutarchian treatise of the same name; *On the Sublime*, attacked by Longinus (?) in his essay on the same subject (see L. Martens, *De Libello Περὶ ὑψους*, 1877); *History of the Servile Wars*, or slave risings in Sicily; *On Rhetoric and Rhetorical Figures*; an *Alphabetical Selection of Phrases*, an Attic lexicon, mentioned by Suidas as one of his authorities; *Against the Phrygians*, probably an attack on the florid style of the Asiatic school of rhetoric.

The fragments have been collected and edited by T. Burckhardt (1863), and E. Ofenloch (1907); some in C. W. Müller, *Fragmenta Historicorum Graecorum*, iii. C. Burian's *Jahresbericht . . . der klassischen Altertumswissenschaft*, xxiii. (1896), contains full notices of recent works on Caecilius, by C. Hammer. See also J. Brzoska in *Pauly-Wissowa, Realencyklopädie* (1897).

**CAECILIUS STATIUS** or **STATIUS CAECILIUS**, Roman comic poet, friend of Ennius, died in 168 (or 166) B.C. He was born in the territory of the Insubrian Gauls, and was probably taken as a prisoner to Rome (c. 200), during the great Gallic war. Originally a slave, he assumed the name of Caecilius from his patron. He supported himself by adapting Greek plays for the Roman stage from the new comedy writers, especially Menander. Suetonius' life of Terence states that Caecilius was ordered to hear Terence's *Andria* (exhibited 166 B.C.) read and to criticize it. Volcarius Sedigitus, the dramatic critic, places him

first amongst the comic poets; Varro praises his plots; Horace (*Epistles*, ii. 1. 59) contrasts his dignity with the art of Terence. Quintilian (*Inst. Orat.*, x. 1. 99) speaks somewhat disparagingly of him, and Cicero (*De Optimo Genere Oratorum*, 1.), considers him inferior to Terence in style and Latinity (*Ad. Att.* vii. 3). The fact that his plays could be named without any indication of the author (Cicero, *De Finibus*, ii. 7) is proof of their popularity.

The fragments of his plays are chiefly preserved in Aulus Gellius, who cites several passages from the *Plocium* (necklace) together with the original Greek of Menander. The translation, which is diffuse and by no means close, fails to reproduce the spirit of the original.

**BIBLIOGRAPHY.**—Fragments in Ribbeck, *Scaenicae Romanorum Poesis Fragmenta* (1898). See also W. S. Teuffel, *Caecilius Statius*, etc. (1858); Mommsen, *Hist. of Rome* (Eng. tr.), bk. iii. ch. xiv.; F. Skutsch in Pauly-Wissowa, *Realencyklopädie* (1897).

**CAECINA**, the name of a distinguished Etruscan family of Volaterrae. Graves have been discovered belonging to the family, whose name is still preserved in the river and hamlet of Cecina.

AULUS CAECINA, son of Aulus Caecina, who was defended by Cicero (69 B.C.) took the side of Pompey in the civil wars and published a violent tirade against Caesar, for which he was banished. He recanted in a work called *Querelae*, and was pardoned at the intercession of his friends—above all, of Cicero. Caecina was regarded as an authority on the Etruscan system of divination (*Etrusca Disciplina*), which he tried to harmonize with the doctrines of the Stoics. (See Seneca, *Nat. Quaest.* II, 31-49, for fragments.) Cicero was probably indebted to Caecina in his treatise *De Divinatione*. Some of the correspondence is preserved in Cicero's letters (*Ad Fam.* vi. 5-8; see also ix. and xiii. 66).

AULUS CAECINA ALIENUS, Roman general, was quaestor of Baetica in Spain (A.D. 68). On the death of Nero he supported Galba, who appointed him to the command of a legion in upper Germany but shortly afterwards ordered him to be prosecuted for embezzlement. Caecina went over to Vitellius and was sent to lead half the army into Italy, where Otho had made himself emperor. After crossing the Alps he was defeated near Cremona, but immediately afterwards he was joined by Valens with the rest of the Vitellian forces and the two defeated Otho at the decisive battle of Bedriacum (Betriacum). When Vespasian's supporters invaded Italy, Caecina, who had been sent against them, turned traitor and tried to persuade his army to go over to Vespasian, but he was thrown into chains by the soldiers. After Vespasian's victory he was released and taken into favour, but in 79 he was implicated in a conspiracy against Vespasian and was put to death by order of Titus.

See Tacitus, *Histories*, i. 53, 61, 67-70, ii. 20-25, 41-44, iii. 13; Dio Cassius lxx. 10-14, lxxvi. 16; Plutarch, *Otho*, 7; Suetonius, *Titus*, 6; Zonares xi. 17.

**CAEDMON**, the earliest English Christian poet. His story is known to us only from Baeda (*Hist. Eccl.*, iv. 24). He was (see BEDE) a herdsman, who received a divine call to poetry in a dream. One night, having quitted a company because, from want of skill, he could not comply with the demand made of each guest to sing, he dreamed that there appeared to him a stranger, who commanded him to sing of "the beginning of created things." He pleaded inability, but the stranger insisted, and he was compelled to obey. He found himself uttering "verses which he had never heard." Of Caedmon's song Baeda gives a prose paraphrase, which, he says, represents the sense only, not the arrangement of the words. When Caedmon awoke he remembered the verses and added others. He related his dream to the farm bailiff under whom he worked, and was conducted by him to the monastery at Streanaeshalch (now called Whitby). The abess Hild recognized that the illiterate herdsman had received a gift from heaven, and, to test his powers, proposed that he should render into verse a portion of sacred history which the monks explained. By the following morning he had fulfilled his task. At the request of the abess he became an inmate of the monastery. Throughout the remainder of his life his more learned brethren expounded to him Scripture history, and all he heard he reproduced in poetry.

All his poetry was on sacred themes, and its unvarying aim was to turn men from sin to righteousness. Although many amongst the Angles had essayed to compose religious poetry, none of them, in Baeda's opinion, had approached Caedmon.

Baeda's account of Caedmon's deathbed has often been quoted, and is of singular beauty. It is commonly stated that he died in 680, in the same year as Hild, but for this there is no authority. All we know of his date is that his dream took place during the period (658-680) in which Hild was abbess of Streanaeshalch, and he must have died before Baeda finished his history in 731.

The hymn said to have been composed by Caedmon in his dream is extant. A copy of it, in the Northumbrian dialect, and in a handwriting of the 8th century, appears on a blank page of the Moore ms. of Baeda's History; and five other Latin mss. have the poem (transliterated into a more southern dialect) as a marginal note. In the Old English version of Baeda, ascribed to King Alfred, it is given in the text. Probably the Latin ms. used by the translator contained this addition. It was formerly maintained by some scholars that the extant Old English verses are not Baeda's original, but a mere retranslation from his Latin prose version. The argument was that they correspond too closely with the Latin; Baeda's words, "hic est sensus, non autem ordo ipse verborum," being taken to mean that he had given only a free paraphrase. But the form of the sentences in Baeda's prose shows a close adherence to the parallelistic structure of Old English verse, and the alliterating words in the poem are in nearly every case the most obvious equivalents of those used by Baeda. The sentence quoted above can therefore have been meant only as an apology for the absence of those poetic graces that disappear in translations. Even if the existing verses are a retranslation, it would still be certain that they differ very slightly from the original. It is of course possible to hold that the story of the dream is pure fiction (a similar story is told of the Icelandic poet Hælebjorn Hali), and that the lines which Baeda translated were not Caedmon's at all. But there is little to justify such scepticism. As the hymn is said to have been Caedmon's first essay in verse, its lack of poetic merit is really an argument for its genuineness. There is then no reason to doubt that the nine lines are Caedmon's.

#### THE "CAEDMON POEMS"

This poor fragment is all that can with confidence be affirmed to remain of the voluminous works of the man whom Baeda so highly admired. A considerable body of verse has been known by his name; but among modern scholars the use of the designation is merely a matter of convenience. The so-called Caedmon poems are contained in a ms. written about A.D. 1000, which was given in 1651 by Archbishop Ussher to the famous scholar Francis Junius, and is now in the Bodleian. They consist of paraphrases of parts of Genesis, Exodus and Daniel, and three separate poems, the first on the lamentations of the fallen angels, the second on the "Harrowing of Hell" and the third (a fragment) on the temptation. The subjects correspond so well with those of Caedmon's poetry as described by Baeda that Junius unhesitatingly attributed the poems to him. The ascription was rejected in 1684 by G. Hickes, whose chief argument, based on the dialect is now known to be fallacious, as most "West Saxon" poetry is certainly of Northumbrian origin. Since, however, we learn from Baeda that Caedmon had many imitators, the abstract probability is unfavourable to the assumption that a collection of poems contained in a late 10th century ms. contains any of his work. Modern criticism has shown that the "Caedmon ms." cannot be all by one author. Some portions of it are plainly the work of a Latin scholar. It is possible that some of the rest may be genuine; but in the absence of any basis of comparison, the internal evidence can afford no certainty. On the other hand, the mere unlikeness of any particular passage to the nine lines of the *Hymn* is no reason for denying it to Caedmon.

*Genesis* contains a long passage (ii. 235-851), which differs markedly in style and metre from the rest. This passage is one of the finest in all Old English poetry. In 1877 E. Sievers argued, on linguistic grounds, that it was mainly a translation from a lost poem in Old Saxon, probably by the author of the *Heliland*: a

conclusion brilliantly confirmed in 1894 by the discovery in the Vatican library of a ms. containing 62 lines of the *Heliland* and the original of 28 lines of the interpolated passage of the Old English *Genesis*. The Old Saxon biblical poetry belongs to the mid 9th century; the translation is consequently later.

As *Genesis* begins with a line identical in meaning with the opening of Caedmon's *Hymn*, we may perhaps infer that the writer knew Caedmon's genuine poems; but when, after treating of the revolt of Lucifer, the paraphrast comes to the biblical part of the story, he follows the sacred text with servile fidelity. The ages of the antediluvian patriarchs, for instance, are accurately rendered into verse. In all probability *Genesis* is of Northumbrian origin. The names assigned to the wives of Noah and his three sons (Phercoba, Olla, Olliua, Olliuni) have been traced to an Irish source, and this seems to point to the influence of the Irish missionaries in Northumbria.

*Exodus* is a fine poem, strangely unlike anything else in Old English literature. It is full of martial spirit, yet makes no use of the phrases of the heathen epic. The condensation of the style and the peculiar vocabulary make it somewhat obscure. It is probably of southern origin, and can hardly be supposed to be even an imitation of Caedmon.

*Daniel* is not a great poem, but the narration is lucid and interesting. The author has borrowed some 70 lines from a poetical rendering of the Prayer of Azarias and the Song of the Three Children, of which there is a copy in the Exeter Book. The borrowed portion ends with verse 3 of the canticle, the remainder of which follows in a version for the most part independent. Elsewhere the paraphrast draws only from the canonical book of Daniel. The poem is obviously the work of a scholar.

The three other poems, designated "Book II." in the Junius ms., are characterized by considerable imaginative power and vigour of expression, but show an absence of culture and are somewhat rambling. They abound in passages of fervid religious exhortation. On the whole, they are such as we should expect in the work of the poet celebrated by Baeda, and it seems just possible that we have in these pieces a comparatively little altered specimen of Caedmon's compositions.

Of poems not included in the Junius ms., the *Dream of the Rood* (see CYNWULF) is the only one that has with any plausibility been ascribed to Caedmon. It was affirmed by G. Stephens that the Ruthwell cross, on which a portion of the poem is inscribed in runes, bore on its top-stone the name "Cadmon"; but the traces of runes that are still visible exclude all possibility of this reading. The poem is certainly Northumbrian and earlier than Cynwulf. It would be impossible to prove that Caedmon was not the author, though his authorship of such a work would rank among the miracles of genius.

Certain similarities between passages in *Paradise Lost* and parts of the translation from Old Saxon have given occasion to the suggestion that some scholar may have talked to Milton about the poetry published by Junius, and that the poet may thus have gained some hints. The parallels, however, though interesting, are only such as might be expected to occur between two poets working on the same traditional material.

The name Caedmon (in the mss. of the Old English version of Baeda written *Cedmon*, *Ceadmann*) is not explicable by means of Old English; the statement that it means "boatman" is founded on the corrupt gloss *liburnam*, *ced*, where *ced* is an error for *ceol*. It is most probably the British *Cadman*, intermediate between the Old Celtic *Catumanus* and the modern Welsh *Cadfan*. Possibly the poet may have been of British descent, though the inference is not certain, as British names may sometimes have been given to English children. The name Caedwalla was borne by a king of the West Saxons. The initial element *Caed*—or *Cead* (probably adopted from British names in which it represents *catu*, war) appears combined with an Old English terminal element in the name *Caedbaed* (cf. however the Irish name *Cathbad*), and hypocoristic forms of names containing it were borne by the English saints Ceadda (St. Chad) and his brother Cedd, called Ceadwealla in one ms. A Cadmon witnesses a Buckinghamshire charter of about A.D. 948.

The oldest edition is that of F. Junius (1655). See R. Wülker's re-edition of Grein's *Bibliothek*, Bd. ii. (1895). This work contains also the texts of the *Hymn* and the *Dream of the Rood*. The pictorial illustrations of the Junius ms. were published in 1833 by Sir H. Ellis.

**CAELIA**, the name of two ancient cities in Italy. (1) In Apulia (mod. *Ceglie del Campo*) on the road to Gnathia (q.v.), 5m. S. of Barium. Coins bearing the inscription *Kaίλιων* prove that it was once independent. (2) In Calabria (mod. *Ceglie Messapica*) 25m. W. of Brundisium, and 99ft. above sea-level. There are remains of a prehistoric *enceinte* and several Messapian inscriptions and numerous tombs.

**CAELIUS AURELIANUS** (fl. end of 4th century), Roman medical writer from Sicca in Numidia. His writings on *Chronic Diseases*, his *Quaestiones* on materia medica and on *Diseases of Women* are little more than Latin translations of Soranus of Ephesus (fl. c. A.D. 100). Caelius is chiefly interesting for his clear observations, his differential diagnoses, his recommendation of mechanical, dietetic and hygienic means, and his knowledge of diseases of the chest and of the nervous system. His *De Morbis Acutis* was printed at Lyons, 1567.

See T. Meyer-Steineg, *Das Medizinische System der Methodiker, eine Vorstudie zu C. Aurelianus "De Morbis Acutis"* (Jena, 1916).

**CAELIUS** (MARCUS CAELIUS RUFUS) (82?–48 B.C.), Roman politician, was born at Puteoli on May 28, B.C. 82, the son of a Roman eques of the same name. (But see Nipperdey, *Rheinisches Museum*, xix., 290.) He was educated under the instructions of Crassus and Cicero, and was constantly with Cicero during Cicero's praetorship (66) and subsequently. In 63 he became intimate with Catiline, but according to Cicero was not involved in the conspiracy. In 61 he went to Africa as *comes* to the consul Q. Pompeius Rufus, and on his return in 59 successfully accused C. Antonius, who had been consul with Cicero, of complicity in the Catilinarian conspiracy, in a brilliantly savage speech which still survived in Quintilian's day (Quint. IV., ii., 123, and IX., iii., 58). About that time he was quaestor.

In 56 he was accused of violence (*vis*), at the instance of Clodia, who had been his mistress, and whom he had deserted and saddled with the nickname *quadrantaria Clytaemnestra*. Caelius is probably the Rufus whom Catullus accuses of stealing Clodia from him. Caelius spoke in his own defence and Crassus and Cicero also spoke for him. He was acquitted. In 52 he was tribune and opposed Pompey's measures for bringing Milo to trial. He was induced by Pompey, against his own judgment, not to veto the law of the ten tribunes, allowing Caesar to stand for the consulship in absence.

In 51 Cicero went to Cilicia as proconsul, and Caelius kept him supplied with news from Rome. His letters are preserved in the collection of Cicero's correspondence. One in particular (*Ad Fam.* viii.) gives a vivid account of the proceedings in the senate on the motion of Marcellus to deal with the consular provinces. In 50 he was aedile, and his letters to Cicero are dotted with requests for panthers for his games. About this time he became a supporter of Caesar. In *Ad Fam.* viii. 14, written to Cicero in Aug. 50, he foresees civil war and seems reluctantly determined to join Caesar. In 49 he supported the motion that Pompey should leave for Spain, and immediately afterwards fled to Caesar's camp at Ravenna. Later that year he fought for Caesar in Liguria and Spain. In 48 he was made *praetor peregrinus*, and Caesar left for the war with Pompey. Indignant at being passed over for the urban praetorship in favour of Trebonius, and disappointed in his hopes of a proscription, which would have enabled him to pay his debts, he set up a tribunal as a counter-attraction to Trebonius, who was administering Caesar's scheme for payment of debts, and introduced measures amounting to a general cancellation of debts. The senate deprived him of his office, and he left Rome to join Milo in Campania. The two of them got up a revolt and were both killed, Caelius at Thurii, by some provincial cavalry whom he was trying to bribe. Brilliant and cynical, capable of impetuous acts of kindness or savagery, he captured the imagination of antiquity, and most authorities have a good word for him. He lives more vividly than most of the men of his age, in his letters to Cicero.

See Cicero, *Pro Caelio*, *Epp. ad. Fam.*; the Introduction to Tyrrell and Purser's *Correspondence of Cicero* (Dublin, 1896), vol. iii.; for his style see F. Becher, *Ueber den Sprachgebrauch des Caelius* (Ufeld, 1888).

**CAEN**, a city of north-western France, capital of the department of Calvados,  $7\frac{1}{2}$  m. from the English Channel and 149 m. W.N.W. of Paris on the Western railway to Cherbourg. Pop. (1926) 46,703. The castle, founded by William the Conqueror and completed by Henry I., is still employed as barracks, though in a greatly altered condition. St. Pierre, the most beautiful church in Caen, stands at the northern extremity of the rue St. Jean, in the centre of the town. In the main, its architecture is Gothic, but the choir and the apsidal chapels, with their elaborate interior and exterior decoration, are of Renaissance workmanship. The graceful tower, which rises beside the southern portal to a height of 255 ft., belongs to the early 14th century. The church of St. Étienne, or l'Abbaye-aux-Hommes, in the west of the town, is an important specimen of Romanesque architecture, dating from about 1070, when it was founded by William the Conqueror. A marble slab marks the former resting-place of William the Conqueror. The abbey-buildings were rebuilt in the 17th and 18th centuries, and now shelter the lycée. Matilda, wife of the Conqueror, was the foundress of the church of La Trinité or l'Abbaye-aux-Dames, which is of the same date as St. Étienne. Other interesting old churches are those of St. Sauveur, St. Michel de Vaucelles, St. Jean, St. Gilles, Notre-Dame de la Gloriette, St. Étienne le Vieux and St. Nicolas, the last two now secularized. The monuments at Caen include one to the natives of Calvados killed in 1870 and 1871 and one to the lawyer J. C. F. Demolombe, together with statues of Louis XIV., Élie de Beaumont, Pierre Simon, marquis de Laplace, D. F. E. Auber and François de Malherbe, the two last, natives of the town. Caen is the seat of a court of appeal, of a court of assizes and of a prefect. It is the centre of an academy and has a university with faculties of law, science and letters and a preparatory school of medicine and pharmacy; there are also a lycée, training colleges, schools of art and music, and two large hospitals. Caen, despite a diversity of manufactures, is commercial rather than industrial. In the south-east of the town there is a floating basin lined with quays and connected with the Orne and with the canal which debouches into the sea at Ouistreham 9 m. to the N.N.E. The port, which also includes a portion of the river-bed, communicates with Havre and Newhaven by a regular line of steamers; it has a considerable fishing population. The industries of Caen include timber-sawing, metal-founding and machine-construction, cloth-weaving, lace-making, the manufacture of leather and gloves, and of oil from the colza grown in the district, furniture and other wooden goods and chemical products.

Though Caen is not a town of great antiquity, the date of its foundation is unknown. It existed as early as the 9th century, and when, in 912, Neustria was ceded to the Normans by Charles the Simple, it was a large and important place. Under the dukes of Normandy, and particularly under William the Conqueror, it rapidly increased. It became the capital of lower Normandy, and in 1346 was besieged and taken by Edward III. of England. It was again taken by the English in 1417, and was retained by them till 1450, when it capitulated to the French. The university was founded in 1436 by Henry VI. of England. During the Wars of Religion, Caen embraced the reform; in the succeeding century its prosperity was shattered by the revocation of the Edict of Nantes (1685). In 1793 the city was the focus of the Girondist movement against the Convention.

See G. Mancel et C. Woinez, *Hist. de la ville de Caen et de ses progrès* (Caen, 1836); B. Pont, *Hist. de la ville de Caen, ses origines* (Caen, 1866); E. de R. de Beaurepaire, *Caen illustré: son histoire, ses monuments* (Caen, 1896).

**CAEPIO, QUINTUS SERVILIUS**, Roman general, consul 106 B.C. During his year of office he brought forward a law by which the jurymen were again to be chosen from the senators instead of the equites (Tacitus, *Ann.* xii. 60; but see Mommsen, *Römisches Staatsrecht*, iii. 531, 2.). As governor of Gallia Narbonensis, he plundered the temple of the Celtic Apollo at Tolosa (Toulouse), the inhabitants of which had joined the Cimbri. In

105 Caepio suffered a crushing defeat from the Cimbri at Arausio (Orange). In the same year he was deprived of his proconsulship and his property confiscated; subsequently he was expelled from the senate, convicted of embezzlement and misconduct, and imprisoned. He either died during his imprisonment or escaped to Smyrna.

See Livy, *Epit.* 67; Valerius Maximus, iv. 7. 3; Justin xxxii. 3; Aulus Gellius iii. 9.

**CAERE**, an ancient city of Etruria (mod. *Cerveteri*, i.e., *Caere vetus*), about 5m. from the sea coast and about 20m. N.W. of Rome, directly reached by a branch road from the Via Aurelia. Ancient writers tell us that its original Pelasgian name was Agylla, and that the Etruscans took it and called it Caere, but the former name lasted on into later times as well as Caere. It was one of the twelve cities of Etruria and had much trade through its port Pyrgos (*q.v.*). After the invasion of the Gauls in 390 B.C., the vestal virgins and the sacred objects in their custody were conveyed to Caere for safety, from which some derive the word *caerimonia*, ceremony. A treaty was made between Rome and Caere in the same year. In 353, however, Caere took up arms against Rome out of friendship for Tarquinii, but was defeated and partially incorporated in the Roman state without internal autonomy or voting rights for its members. The status is known as the *ius Caeritum*, and Caere was the first of a class of such municipalities. Under Augustus and Tiberius its prosperity was to a certain extent restored, and inscriptions speak of its municipal officials (the chief of them called *dictator*) and its town council, which had the title of *senatus*. In the middle ages, however, it sank in importance, and early in the 13th century, a part of the inhabitants founded Caere novum (mod. *Ceri*) 3m. to the east.

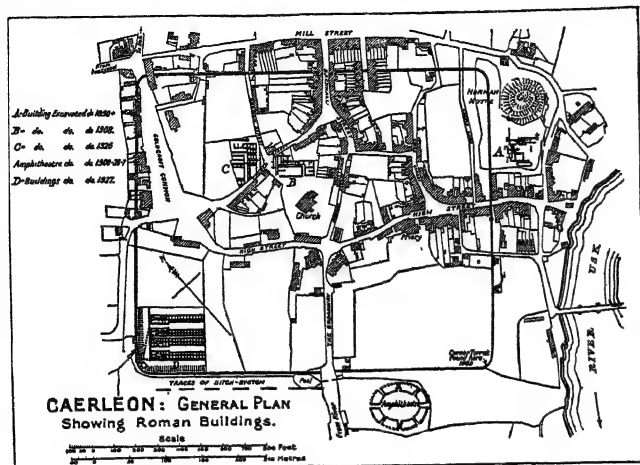

The town lay on a hill of tufa, running from north-east to south-west, isolated except on the north-east, and about 300ft. above sea-level. The modern town, at the western extremity, probably occupies the site of the acropolis. There seem to have been eight gates in the circuit of the city walls which was about 4m. in length. In the theatre many inscriptions and statues of emperors were found. The necropolis on the hill to the north-west, known as the Banditaccia, is far more imposing: it has the aspect of a veritable city of the dead, the tombs being in rows divided by paved streets. The larger tomb chambers are hewn in the rock and covered by mounds, but though many tombs have been excavated they are estimated at only 2½% of the whole. Several of them are interesting from their architectural and decorative details. The most important tomb of all, the Regolini-Galassi tomb (taking its name from its discoverers), which lies south-west of the ancient city, is a narrow rock-hewn chamber about 60ft. long, lined with masonry, the sides converging to form the roof. The objects found in it (a chariot, a bed, silver goblets with reliefs, rich gold ornaments, etc.) are now in the Etruscan Museum at the Vatican: they are attributed to about the middle of the seventh century B.C.

See Randall-MacIver, *Villanovans and Early Etruscans*, 195 sqq. (Oxford, 1924); *Studi Etruschi*, 145 sqq. (Florence, 1927).

**CAERLEON**, a country village in the southern parliamentary division of Monmouthshire, England, on the right (west) bank of the Usk, 3 m. N.E. of Newport. Pop. (1931) 2,326. Its claim to notice rests on its importance as the site of the Roman legionary fortress of *Isca* (not *Isca Silurum*), founded and garrisoned by Legio II. Augusta following its campaign against the Silures. This legion had formed the right wing of the expeditionary force of 50,000 men landed in Britain by the emperor Claudius in A.D. 43. According to Tacitus (*Annals* XII., 32) it first entered South Wales in A.D. 50, and from then on until c. A.D. 75 was engaged in the reduction of the Silures. As will be shown, the fortress was probably founded in the latter year. The choice of the site was no doubt dictated by its command of the coastal approach into South Wales, its general accessibility, and its great natural strength. Visible remains of the original works are few. They indicate a rectangular enclosure with rounded angles, 540 yards long by 450 yards broad, with an internal area of roughly 50 acres.

**Recent Excavations.**—The systematic exploration of the site was begun by the National Museum of Wales in 1926. The initial

defences of the fortress, as excavations have now shown, consisted of a V-shaped ditch, 25 feet wide by 8 feet deep, and a clay bank, 20 feet wide by 8 feet high, with an inner revetment of timber. Pottery sherds recovered from the bank together with coin-finds from the site generally show that the fortress was established in the Flavian period, not improbably immediately after the final defeat of the Silures by Julius Frontinus in c. A.D. 75 (Tacitus,

*Agricola*, 17). At a later date, probably towards the close of the century the outer face of the clay bank was strengthened with an embattled stone wall, 5 feet in basal thickness and still standing in places to a height of 12 feet. The wall was pierced by four symmetrically placed gateways and equipped with an elaborate system of internal look-out turrets situated at regular intervals of 50 yards. In the early 3rd century the turrets appear to have been turned into furnace-chambers. A heavily-metalled roadway (the *via sagularis* or *angularis*) skirted the base of the ramparts within. As to the internal lay-out of the fortress, the street-plan of the modern village is evidence that it conformed to type. The fortress was traversed by two streets, the *via principalis* or "principal way" crossing between the two lateral gateways and to-day vaguely followed by Backhall Street, Museum Street, and the Broadway, and the *via quintana*, a lesser street whose original line is roughly indicated by modern Norman Street. A third street that with interruptions ran the length of the fortress between the other two gateways is preserved, if irregularly, in modern High Street. The principal buildings were ranged across the space between the lateral streets (the *principia*). They must have included, among others, the *praetorium* or headquarters building (a large edifice situated in the centre of the space and to-day therefore partly covered by S. Cadoc's Church), the residence of the legionary commander, and perhaps the granaries. Parts of two of these buildings were excavated in 1908 and 1928, but not enough was exposed to identify them.

**Barracks.**—The remainder of the space within the fortress, that in front of the principal buildings (the *praetentura*) and that behind (the *retentura*), was occupied by the barracks of the soldiers and such other buildings as the hospital, the houses of the tribunes, the prison, stables, and various workshops. Part of what may have been a tribune's house or else the hospital was opened up in 1926, while four barrack-buildings lying immediately within the western angle of the fortress and a long narrow unidentified building of probably early 3rd century date backing the north-western rampart were cleared in 1927–8. The barracks consisted as normally of long narrow oblong hutments, each 40 feet wide by 250 feet long, arranged in pairs separated by a narrow alleyway, the buildings of each pair opening on to a common street. Each hutment accommodated a company of 100 men under the command of a centurion. The latter with his assistant non-commissioned officers occupied a spacious suite of rooms at one end of the building, while the men were quartered in a row of twelve double cubicles extending down its length. The drainage

of these and the other buildings within the defences was ensured by a large underground culvert following the inner edge of the rampart-roadway and probably emptying ultimately into the Usk.

**Environs.**—The environs of the fortress, apart from the site of the amphitheatre, have not yet been investigated. But it is certain that the open fields outside the walls to the south and west contain the foundations of more or less extensive "suburbs." These would include bath-buildings, temples, the "married-quarters" of the legionaries, and of course the amphitheatre. In addition, there were the tileries and the cemeteries of the legion. The sites of two bath-buildings have been identified, one between the fortress and the Usk to the south-east and the other immediately to the south-west of the amphitheatre. As to the presence of temples, and inscription (*Corpus Inscriptionum Latinarum*, VII., 95) records the restoration of a temple of Diana in the 3rd century. Exhaustive excavations have laid bare the character and history of the amphitheatre. It was a small oval stone structure of simple type, some 267 feet long by 222 feet broad, with eight entrances. Its seating capacity was about 6,000 persons. It was built in the late 1st century, re-built after a partial collapse in c. A.D. 125, and again re-built after decay in the early 3rd century. Its use seems to have ended with that century. The site of the tileries is not known, but cemeteries have been found to the north-east and north-west of the fortress and across the Usk.

**Chronology.**—Certain details of the history of the fortress have already been given. On present evidence it would appear to fall into two main phases, the first a period of earthen defences and timber buildings, the second when defences and buildings had been given permanent form in stone. The chronology of these phases seems variable. Thus, while the barrack-blocks and certain at least of the other lesser buildings within the fortress were already of stone as early as c. A.D. 100, the principal buildings, strangely enough, seem to have persisted in timber down to at least 200. There are indications that the occupation of the fortress suddenly diminished in the early 2nd century, a diminution probably to be correlated with the known transfer northwards of large detachments of the 2nd Legion for work on Hadrian's Wall. The 3rd century saw a renewal of occupation on an intensive scale. Inscriptions (*C.I.L.* VII., 106–107) datable to this century speak of the reconstruction (? in stone) of the headquarters building (?) and of the re-building of barracks *a solo*. A sequence of coin-finds extending into the 4th century found on the sites of the two buildings excavated in the *principia* suggests the presence of at any rate a cadre garrison as late perhaps as A.D. 350; but against this must be set, on the one hand, the construction about this time of a new coastal fortress of Saxon-Shore type at Cardiff 14 miles away (? as a substitute for a now obsolete inland base) and, on the other, the entry in the early 5th century *Notitia Dignitatum* ascribing the 2nd Legion or part of it to Richborough (*Rutupiae*) in Kent. Life in the suburbs may have lingered on longer—it is perhaps significant that the Latin name *Castra Legionis*, whence is derived the Welsh *Caerleon* (*E. Caerleon*), dates from the 6th century—but it can have had no permanent form as at York (*Eboracum*).

**Legends and Traditions.**—The common notion that Caerleon was the seat of a Christian bishopric in the 4th century is unproved and improbable. Its later recorded history is scarcely less fanciful. Welsh legend has made the site very famous with tales of Arthur (revived by Tennyson in his *Idylls*), of Christian martyrs, Aaron and Julius, and of an archbishopric held by St. Dubric and shifted to St. David's in the 6th century. But most of these traditions date from Geoffrey of Monmouth (about 1130–1140), and must not be taken for history. The ruins of Caerleon attracted notice in the 12th and following centuries, and gave plain cause for legend-making. There is better, but still slender, reason for the belief that it was here, and not at Chester, that five kings of the Cymry rowed Edgar in a barge as a sign of his sovereignty (A.D. 973).

See Lee, *Isca Silurum* (1862) and Supplement (1868), a catalogue of the objects in the Caerleon Museum; *C.I.L.* (1873) VII., 95–136

(Hubner) and *Ephemeris Epigraphica* (Haverfield); Liverpool Committee for Research in Wales Report (1908), 53-82 (Evelyn-White); Wheeler, *Prehistoric and Roman Wales; Archaeologia Cambrensis* (1927), 380-384 (Nash-Williams) for a discussion of the name; *ib.* (1928), 1-32 (Wheeler), preliminary report on the excavation of the amphitheatre.

**CAERPHILLY**, Glamorganshire, Wales, 7m. from Cardiff, and 6m. from Pontypridd. The origin of the name is unknown. It was formerly in the ancient parish of Eglwysilan, but from that and Bedwas, Mon., an ecclesiastical parish was formed in 1850, while the whole of the parishes of Eglwysilan and Llanfabon were in 1893 constituted into an urban district; its population in 1931 was 35,760. The ancient commote of Senghenydd (corresponding to the modern hundred of Caerphilly) comprised the mountainous district from the ridge of Cefn On on the south to Breconshire on the north, being bounded by the rivers Taff and Rhymney on the west and east. Its inhabitants, though nominally subject to the lords of Glamorgan since Fitzhamon's conquest, often raided the lowlands. To keep these in check, Gilbert de Clare, during the closing years of the reign of Henry III., built the castle of Caerphilly on the southern edge of this district, in a wide plain between the two rivers. Prince Llewelyn ap Griffith laid siege to it in 1271. Subsequently completed, it became "the earliest and the most complete example in Britain of a concentric castle of the type known as 'Edwardian'." The great hall is a fine example of Decorated architecture. This and other additions are attributed to Hugh le Despenser (1318-26). It was attacked by Owain Glyn Dwr in 1403. Before the middle of the 15th century it had ceased to be a fortified residence and was used as a prison, but its ruins at the present day are extensive and imposing.

The town grew up around the castle but never received a charter or had a governing body. Its markets during the 19th century were chiefly noted for the Caerphilly cheese sold there. The district was one of the chief centres of the Methodist revival of the 18th century, the first synod of the Calvinistic Methodists being held in 1743 at Watford farm close to the town. With the development of the south Wales coal-field the prosperity of Caerphilly greatly increased. In 1858 was opened the Rhymney railway from Rhymney to Caerphilly and on to Taff's Well, whence it had running powers over the Taff Vale railway to Cardiff, but in 1871, by means of the Cefn On tunnel a direct line was made to Cardiff. A branch line, 4m. long, was opened in 1894 to Senghenydd. The Pontypridd and Newport railway was constructed in 1887, and there is a joint station at Caerphilly for both railways. Trade depression since 1921 has had especially marked effects in this locality.

**CAESALPINUS (CESALPINO), ANDREAS** (1519-1603), Italian botanist and physician, was born in Arezzo in Tuscany in 1519. He studied anatomy and medicine at the University of Pisa, where he took his doctor's degree in 1551, and in 1555 became professor of *materia medica* and director of the botanical garden. Appointed physician to Pope Clement VIII., he removed in 1592 to Rome where he died on Feb. 23, 1603. Caesalpinus was the most distinguished botanist of his time. His work, *De Plantis libri xvi.* (Florence, 1583), was the source from which various subsequent writers, and especially Robert Morison (1620-83) derived their ideas of botanical arrangement. Linnaeus himself gratefully avowed his obligations to Caesalpinus. Caesalpinus was also distinguished as a physiologist, and it has been claimed that he had a clear idea of the circulation of the blood. His other works include *Daemonum investigatio peripatetica* (1580), *Quaestionum medicarum libri ii.* (1593), *De Metallicis* (1596), and *Quaestionum peripateticarum libri v.* (1571).

See V. Viviani, *Vita ed Opere di Andrea Cesalpino* (Arezzo, 1922).

**CAESAR, GAIUS JULIUS (IULIUS)** (102?-44 B.C.), the great Roman soldier and statesman, was born on July 12, 102 B.C. (In spite of the explicit statements of Suetonius, Plutarch, and Appian that Caesar was in his 56th year at the time of his murder, it is, as Mommsen has shown, probable that he was born in 102 B.C., since he held the chief offices of state in regular order, beginning with the aedileship in 65 B.C., and the legal age for this was fixed at 37-38.) His family was of patrician rank and traced a legendary descent from Iulus, the founder of Alba

Longa, son of Aeneas, and grandson of Venus and Anchises. Caesar made the most of his divine ancestry and built a temple in his forum to Venus Genetrix; but his patrician descent was of little importance in politics and disqualified Caesar from holding the tribunate, an office to which, as a leader of the popular party, he would naturally have aspired. The Iulii Caesares, however, had also acquired the new *nobilitas*, which belonged to holders of the great magistracies. Caesar's uncle was consul in 91 B.C., and his father held the praetorship. Most of the family seem to have belonged to the senatorial party (*optimates*); but Caesar himself was from the first a *popularis*. The determining factor is no doubt to be sought in his relationship with C. Marius, the husband of his aunt Iulia. Caesar was born in the year of Marius's first great victory over the Teutones, and as he grew up, inspired by the traditions of the great soldier's career, attached himself to his party and its fortunes. Of his education we know scarcely anything. His mother, Aurelia, belonged to a distinguished family, and Tacitus (*Dial. de Orat.* xxviii.) couples her name with that of Cornelia, the mother of the Gracchi, as an example of the Roman matron whose *disciplina* and *severitas* formed her son for the duties of a soldier and statesman. His tutor was M. Antonius Gniphio, a native of Gaul (by which Cisalpine Gaul may be meant), who is said to have been equally learned in Greek and Latin literature and to have set up in later years a school of rhetoric which was attended by Cicero in his praetorship 66 B.C. It is possible that Caesar may have derived from him his interest in Gaul and its people and his sympathy with the claims of the Romanized Gauls of northern Italy to political rights.

In his 16th year (87 B.C.) Caesar lost his father, and assumed the *toga virilis* as the token of manhood. The Social War (90-89 B.C.) had been brought to a close by the enfranchisement of Rome's Italian subjects; and the civil war which followed it led, after the departure of Sulla for the East, to the temporary triumph of the *populares*, led by Marius and Cinna, and the indiscriminate massacre of their political opponents, including both of Caesar's uncles. Caesar was at once marked out for high distinction, being created *flamen Dialis* or priest of Jupiter. In the following year (which saw the death of Marius) Caesar, rejecting a proposed marriage with a wealthy capitalist's heiress, sought and obtained the hand of Cornelia, the daughter of Cinna, and thus became further identified with the ruling party. His career was soon after interrupted by the triumphant return of Sulla (82 B.C.), who ordered him to divorce his wife, and on his refusal deprived him of his property and priesthood and was induced to spare his life only by the intercession of his aristocratic relatives and the college of Vestal virgins.

Released from his religious obligations, Caesar now (81 B.C.) left Rome for the East and served his first campaign under Minucius Thermus, who was engaged in stamping out the embers of resistance to Roman rule in the province of Asia, and received from him the "civic crown" for saving a fellow-soldier's life at the storm of Mytilene. In 78 B.C. he was serving under Servilius Isauricus against the Cilician pirates when the news of Sulla's death reached him and he at once returned to Rome. Refusing to entangle himself in the abortive and equivocal schemes of Lepidus to subvert the Sullan constitution, Caesar took up the only instrument of political warfare left to the opposition by prosecuting two senatorial governors, Cn. Cornelius Dolabella (in 77 B.C.) and C. Antonius (in 76 B.C.) for extortion in the provinces of Macedonia and Greece, and, though he lost both cases, probably convinced the world at large of the corruption of the senatorial tribunals. After these failures Caesar determined to take no active part in politics for a time and retraced his steps to the East in order to study rhetoric under Molon, at Rhodes. On the journey thither he was caught by pirates, whom he treated with consummate nonchalance while awaiting his ransom, threatening to return and crucify them; when released he lost no time in carrying out his threat. Whilst he was studying at Rhodes the third Mithridatic War broke out, and Caesar at once raised a corps of volunteers and helped to secure the wavering loyalty of the provincials of Asia. When Lucullus assumed the command of the Roman troops in Asia, Caesar returned to Rome, to find

that he had been elected to a seat on the college of *pontifices* left vacant by the death of his uncle, C. Aurelius Cotta. He was likewise elected first of the six *tribuni militum a populo*, but we hear nothing of his service in this capacity. Suetonius tells us that he threw himself into the agitation for the restoration of the ancient powers of the tribunate curtailed by Sulla, and that he secured the passing of a law of amnesty in favour of the partisans of Sertorius. He was not, however, destined to compass the downfall of the Sullan régime; the crisis of the Slave War placed the senate at the mercy of Pompey and Crassus, who in 70 B.C. swept away the safeguards of senatorial ascendancy, restored the initiative in legislation to the tribunes, and replaced the Equestrian order, *i.e.*, the capitalists, in partial possession of the jury-courts. This judicial reform (or rather compromise) was the work of Caesar's uncle, L. Aurelius Cotta. Caesar himself, however, gained no accession of influence. In 69 B.C. he served as quaestor under Antistius Vetus, governor of Hither Spain, and on his way back to Rome (according to Suetonius) promoted a revolutionary agitation amongst the Transpadanes for the acquisition of full political rights, which had been denied them by Sulla's settlement.

**Caesar and Pompey.**—Caesar was now best known as a man of pleasure, celebrated for his debts and his intrigues; in politics he had no force behind him save that of the discredited party of the *populares*, reduced to lending a passive support to Pompey and Crassus. But as soon as the proved incompetence of the senatorial government had brought about the mission of Pompey to the East with the almost unlimited powers conferred on him by the Gabinian and Manilian laws of 67 and 66 B.C. (see POMPEY), Caesar plunged into a network of political intrigues which it is no longer possible to unravel. In his public acts he lost no opportunity of upholding the democratic tradition. Already in 68 B.C. he had paraded the bust of Marius at his aunt's funeral; in 65 B.C. as curule aedile, he restored the trophies of Marius to their place on the Capitol; in 64 B.C., as president of the murder commission, he brought three of Sulla's executioners to trial, and in 63 B.C. he caused the ancient procedure of trial by popular assembly to be revived against the murderer of Saturninus. By these means, and by the lavishness of his expenditure on public entertainments as aedile, he acquired such popularity with the plebs that he was elected *pontifex maximus* in 63 B.C. against such distinguished rivals as Q. Lutatius Catulus and P. Servilius Isauricus. But all this was on the surface. There can be no doubt that Caesar was cognizant of some at least of the threads of conspiracy which were woven during Pompey's absence in the East. According to one story, the *enfants perdus* of the revolutionary party—Catiline, Autronius, and others—designed to assassinate the consuls on Jan. 1, 65, and make Crassus dictator, with Caesar as master of the horse. We are also told that a public proposal was made to confer upon him an extraordinary military command in Egypt, not without a legitimate king and nominally under the protection of Rome. An equally abortive attempt to create a counterpoise to Pompey's power was made by the tribune Rullus at the close of 64 B.C. He proposed to create a land commission with very wide powers, which would in effect have been wielded by Caesar and Crassus. The bill was defeated by Cicero, consul in 63 B.C. In the same year the conspiracy associated with the name of Catiline came to a head. The charge of complicity was freely levelled at Caesar, and indeed was hinted at by Cato in the great debate in the senate. But Caesar, for party reasons, was bound to oppose the execution of the conspirators; while Crassus, who shared in the accusation, was the richest man in Rome and the least likely to further anarchist plots. Both, however, doubtless knew as much and as little as suited their convenience of the doings of the left wing of their party, which served to aggravate the embarrassments of the government.

As praetor (62 B.C.) Caesar supported proposals in Pompey's favour which brought him into violent collision with the senate. This was a master-stroke of tactics, as Pompey's return was imminent. Thus when Pompey landed in Italy and disbanded his army he found in Caesar a natural ally. After some delay, said

to have been caused by the exigencies of his creditors, which were met by a loan of £200,000 from Crassus, Caesar left Rome for his province of Further Spain, where he was able to retrieve his financial position and to lay the foundations of a military reputation. He returned to Rome in 60 B.C. to find that the senate had sacrificed the support of the capitalists (which Cicero had worked so hard to secure), and had finally alienated Pompey by refusing to ratify his acts and grant lands to his soldiers. Caesar at once approached both Pompey and Crassus, who alike detested the existing system of government but were personally at variance, and succeeded in persuading them to forget their quarrel and join him in a coalition which should put an end to the rule of the oligarchy. He even made a generous, though unsuccessful, endeavour to enlist the support of Cicero. The so-called First Triumvirate was formed, and constitutional government ceased to exist save in name.

The first prize which fell to Caesar was the consulship, to secure which he forewent the triumph which he had earned in Spain. His colleague was M. Bibulus, who belonged to the strictest sect of the senatorial oligarchy and, together with his party, placed every form of constitutional obstruction in the path of Caesar's legislation. Caesar, however, overrode all opposition, mustering Pompey's veterans to drive his colleague from the forum. Bibulus became a virtual prisoner in his own house, and Caesar placed himself outside the pale of the free republic. Thus the programme of the coalition was carried through. Pompey was satisfied by the ratification of his acts in Asia, and by the assignment of the Campanian state domains to his veterans, the capitalists (with whose interests Crassus was identified) had their bargain for the farming of the Asiatic revenues cancelled, Ptolemy Auletes received the confirmation of his title to the throne of Egypt (for a consideration amounting to £1,500,000), and a fresh act was passed for preventing extortion by provincial governors.

**The Gallic Wars.**—It was now all-important for Caesar to secure practical irresponsibility by obtaining a military command. The senate, in virtue of its constitutional prerogative, had assigned as the *provincia* of the consuls of 59 B.C. the supervision of roads and forests in Italy. Caesar secured the passing of a legislative enactment conferring upon himself the government of Cisalpine Gaul and Illyricum for five years, and exacted from the terrorized senate the addition of Transalpine Gaul, where, as he well knew, a storm was brewing which threatened to sweep away Roman civilization beyond the Alps. The mutual jealousies of the Gallic tribes had enabled German invaders first to gain a foothold on the left bank of the Rhine, and then to obtain a predominant position in Central Gaul. In 60 B.C. the German king Ariovistus had defeated the Aedui, who were allies of Rome, and had wrested from the Sequani a large portion of their territory. Caesar must have seen that the Germans were preparing to dispute with Rome the mastery of Gaul; but it was necessary to gain time, and in 59 B.C. Ariovistus was inscribed on the roll of the friends of the Roman people. In 58 B.C. the Helvetii, a Celtic people inhabiting Switzerland, determined to migrate for the shores of the Atlantic and demanded a passage through Roman territory. According to Caesar's statement they numbered 368,000, and it was necessary at all hazards to save the Roman province from the invasion. Caesar had but one legion beyond the Alps. With this he marched to Geneva, destroyed the bridge over the Rhone, fortified the left bank of the river, and forced the Helvetii to follow the right bank. Hastening back to Italy he withdrew his three remaining legions from Aquileia, raised two more, and, crossing the Alps by forced marches, arrived in the neighbourhood of Lyons to find that three-fourths of the Helvetii had already crossed the Saône, marching westward. He destroyed their rearguard, the Tigurini, as it was about to cross, transported his army across the river in 24 hours, pursued the Helvetii in a northerly direction, and utterly defeated them at Bibracte (Mont Beuvray). Of the survivors a few were settled amongst the Aedui; the rest were sent back to Switzerland lest it should fall into German hands.

The Gallic chiefs now appealed to Caesar to deliver them from the actual or threatened tyranny of Ariovistus. He at once de-

manded a conference, which Ariovistus refused, and on hearing that fresh swarms were crossing the Rhine marched with all haste to Vesontio (Besançon) and thence by way of Belfort into the plain of Alsace, where he gained a decisive victory over the Germans, of whom only a few (including Ariovistus) reached the right bank of the Rhine in safety. These successes roused natural alarm in the minds of the Belgae—a confederacy of tribes in the north-west of Gaul, whose civilization was less advanced than that of the Celtae of the centre—and in the spring of 57 B.C. Caesar determined to anticipate the offensive movement which they were understood to be preparing and marched northwards into the territory of the Remi (about Reims), who alone amongst their neighbours were friendly to Rome. He successfully checked the advance of the enemy at the passage of the Aisne (between Laon and Reims) and their ill-organized force melted away as he advanced. But the Nervii and their neighbours farther to the north-west remained to be dealt with, and were crushed only after a desperate struggle on the banks of the Sambre, in which Caesar was forced to expose his person in the *mêlée*. Finally, the Aduatuci (near Namur) were compelled to submit, and were punished for their subsequent treachery by being sold wholesale into slavery. In the meantime Caesar's lieutenant, P. Crassus, received the submission of the tribes of the north-east, so that by the close of the campaign almost the whole of Gaul—except the Aquitani in the south-west—acknowledged Roman suzerainty.

In 56 B.C., however, the Veneti of Brittany threw off the yoke and detained two of Crassus's officers as hostages. Caesar, who had been hastily summoned from Illyricum, crossed the Loire and invaded Brittany, but found that he could make no headway without destroying the powerful fleet of high, flat-bottomed boats like floating castles possessed by the Veneti. A fleet was hastily constructed in the estuary of the Loire, and placed under the command of Decimus Brutus. The decisive engagement was fought (probably) in the Gulf of Morbihan and the Romans gained the victory by cutting down the enemy's rigging with sickles attached to poles. As a punishment for their treachery, Caesar put to death the senate of the Veneti and sold their people into slavery. Meanwhile Sabinus was victorious on the northern coasts, and Crassus subdued the Aquitani. At the close of the season Caesar raided the territories of the Morini and Menapii in the extreme north-west.

In 55 B.C. certain German tribes, the Usipetes and Tencteri, crossed the lower Rhine and invaded the modern Flanders. Caesar at once marched to meet them and, on the pretext that they had violated a truce, seized their leaders, who had come to parley with him, and then surprised and practically destroyed their host. His enemies in Rome accused him of treachery, and Cato even proposed that he should be handed over to the Germans. Caesar meanwhile constructed his famous bridge over the Rhine in ten days, and made a demonstration of force on the right bank. In the remaining weeks of the summer he made his first expedition to Britain, and this was followed by a second crossing in 54 B.C. On the first occasion Caesar took with him only two legions, and effected little beyond a landing on the coast of Kent. The second expedition consisted of five legions and 2,000 cavalry, and set out from the Portus Itius (Boulogne or Wissant; see T. Rice Holmes, *Ancient Britain and the Invasions of Julius Caesar*, 1907, later views in *Classical Review*, May 1909, and H. S. Jones, in *Eng. Hist. Rev.* xxiv., 1909, p. 115). Caesar now penetrated into Middlesex and crossed the Thames, but the British prince Cassivellaunus with his war-chariots harassed the Roman columns, and Caesar was compelled to return to Gaul after imposing a tribute which was never paid.

The next two years witnessed the final struggle of the Gauls for freedom. Just before the second crossing to Britain, Dumnorix, an Aeduan chief, had been detected in treasonable intrigues and killed in an attempt to escape from Caesar's camp. At the close of the campaign Caesar distributed his legions over a somewhat wide extent of territory. Two of their camps were treacherously attacked. At Aduatuca (near Aix-la-Chapelle) a newly-raised legion was cut to pieces by the Eburones under Ambiorix, while Quintus Cicero was besieged in the neighbourhood of Namur

and only just relieved in time by Caesar, who was obliged to winter in Gaul in order to check the spread of the rebellion. Indutiomarus, indeed, chief of the Treveri (about Trèves), revolted and attacked Labienus, but was defeated and killed. The campaign of 53 B.C. was marked by a second crossing of the Rhine and by the destruction of the Eburones, whose leader Ambiorix, however, escaped. In the autumn Caesar held a conference at Durocortorum (Reims), and Acco, a chief of the Senones, was convicted of treason and flogged to death.

Early in 52 B.C. some Roman traders were massacred at Cenabum (Orleans), and on hearing the news the Arverni revolted under Vercingetorix and were quickly joined by other tribes, especially the Bituriges, whose capital was Avaricum (Bourges). Caesar hastened back from Italy, slipped past Vercingetorix and reached Agedincum (Sens), the headquarters of his legions. Vercingetorix saw that Caesar could not be met in open battle, and determined to concentrate his forces in a few strong positions. Caesar first besieged and took Avaricum, whose occupants were massacred, and then invested Gergovia (near the Puy-de-Dôme), the capital of the Arverni, but suffered a severe repulse and was forced to raise the siege. Hearing that the Roman province was threatened, he marched westward, defeated Vercingetorix near Dijon and shut him up in Alesia (Mont-Auxois), which he surrounded with lines of circumvallation. An attempt at relief by Vercassivellaunus was defeated after a desperate struggle and Vercingetorix surrendered. The struggle was over except for some isolated operations in 51 B.C., ending with the siege and capture of Uxellodunum (Puy d'Issolu), whose defenders had their hands cut off. Caesar now reduced Gaul to the form of a province, fixing the tribute at 40,000,000 sesterces (£350,000) and dealing liberally with the conquered tribes, whose cantons were not broken up.

**The Civil War.**—In the meantime his own position was becoming critical. In 56 B.C., at the conference of Luca (Lucca), Caesar, Pompey, and Crassus had renewed their agreement and Caesar's command in Gaul, which would have expired on March 1, 54 B.C., was renewed, probably for five years, *i.e.*, to March 1, 49 B.C., and it was enacted that the question of his successor should not be discussed until March 1, 50 B.C., by which time the provincial commands for 49 B.C., would have been assigned, so that Caesar would retain *imperium*, and thus immunity from persecution, until the end of 49 B.C. He was to be elected consul for 48 B.C., and, as the law prescribed a personal canvass, he was by special enactment dispensed from its provisions. But in 54 B.C. Julia, the daughter of Caesar and wife of Pompey, died, and in 53 B.C., Crassus was killed at Carrhae. Pompey now drifted apart from Caesar and became the champion of the senate. In 52 B.C. he passed a fresh law *de iure magistratuum*, which cut away the ground beneath Caesar's feet by making it possible to provide a successor to the Gallic provinces before the close of 49 B.C., which meant that Caesar would become for some months a private person, and thus liable to be called to account for his unconstitutional acts. Caesar had no resource left but uncompromising obstruction, which he sustained by enormous bribes. His representative in 50 B.C., the tribune C. Scribonius Curio, served him well, and induced the lukewarm majority of the senate to refrain from extreme measures, insisting that Pompey, as well as Caesar, should resign the *imperium*. But all attempts at negotiation failed, and in Jan. 49 B.C., martial law having been proclaimed on the proposal of the consuls, the tribunes Antony and Cassius fled to Caesar, who crossed the Rubicon (the frontier of Italy) with a single legion, exclaiming "*Alea iacta est.*"

Pompey's available force consisted in two legions stationed in Campania and eight, commanded by his lieutenants, Afranius and Petreius, in Spain; both sides levied troops in Italy. Caesar was soon joined by two legions from Gaul and marched rapidly down the Adriatic coast, overtaking Pompey at Brundisium (Brindisi), but failing to prevent him from embarking with his troops for the East, where the prestige of his name was greatest. Hereupon Caesar (it is said) exclaimed "I am going to Spain to fight an army without a general, and thence to the East to fight a general without an army." He carried out the first part of

this programme with marvellous rapidity. He reached Ilerda (Lerida) on June 23, and, after extricating his army from a perilous situation, outmanoeuvred Pompey's lieutenants and received their submission on Aug. 2. Returning to Rome, he held the dictatorship for 11 days, was elected consul for 48 B.C., and set sail for Epirus at Brundisium on Jan. 4. He attempted to invest Pompey's lines at Dyrrhachium (Durazzo), though his opponent's force was double that of his own, and was defeated with considerable loss. He now marched eastwards, in order if possible to intercept the reinforcements which Pompey's father-in-law, Scipio, was bringing up; but Pompey was able to effect a junction with this force and descended into the plain of Thessaly, where at the battle of Pharsalus he was decisively defeated and fled to Egypt, pursued by Caesar, who learnt of his rival's murder on landing at Alexandria. Here he remained for nine months, fascinated (if the story be true) by Cleopatra, and almost lost his life in an *émeute*. In June 47 B.C., he proceeded to the East and Asia Minor, where he "came, saw, and conquered" Pharnaces, son of Mithridates the Great, at Zela. Returning to Italy, he quelled a mutiny of the legions (including the faithful Tenth) in Campania and crossed to Africa, where a republican army of 14 legions under Scipio was cut to pieces at Thapsus (April 6, 46 B.C.). Here most of the republican leaders were killed and Cato committed suicide. On July 26-29 Caesar celebrated a fourfold triumph and received the dictatorship for ten years. In November, however, he was obliged to sail for Spain, where the sons of Pompey still held out. On March 17, 45 B.C., they were crushed at Munda. Caesar returned to Rome in September, and six months later (March 15, 44 B.C.) was murdered in the senate house at the foot of Pompey's statue.

**Caesar's Dictatorship.**—It was remarked by Seneca that amongst the murderers of Caesar were to be found more of his friends than of his enemies. We can account for this only by emphasizing the fact that the form of Caesar's government became as time went on more undisguised in its absolutism, while the honours conferred upon him seemed designed to raise him above the rest of humanity. It is explained elsewhere (*see* *ROME: History, Ancient*) that Caesar's power was exercised under the form of the dictatorship. In the first instance (autumn of 49 B.C.) this was conferred upon him as the only solution of the constitutional deadlock created by the flight of the magistrates and senate, in order that elections (including that of Caesar himself to the consulship) might be held in due course. For this there were republican precedents. In 48 B.C. he was created dictator for the second time, probably with constituent powers and for an undefined period, according to the dangerous and unpopular precedent of Sulla. In May 46 B.C. a third dictatorship was conferred on Caesar, this time for ten years and apparently as a yearly office, so that he became Dictator IV. in May 45 B.C. Finally, before Feb. 15, 44 B.C., this was exchanged for a life-dictatorship. Not only was this a contradiction in terms, since the dictatorship was by tradition a makeshift justified only when the state had to be carried through a serious crisis, but it involved military rule in Italy and the permanent suspension of the constitutional guarantees, such as *intercessio* and *provocatio*, by which the liberties of Romans were protected. Besides the dictatorship, Caesar held the consulship in each year of his reign except 47 B.C. (when no curule magistrates were elected save for the last three months of the year); and he was, moreover, invested by special enactments with a number of other privileges and powers; of these the most important was the *tribunicia potestas*, which we may believe to have been free from the limits of place (*i.e.*, Rome) and collegiality. Thus, too, he was granted the sole right of making peace and war and of disposing of the funds in the treasury of the state.<sup>1</sup> Save for the title of dictator, which undoubtedly carried unpopular associations and was formally abolished on the proposal of Antony

after Caesar's death, this cumulation of powers has little to distinguish it from the Principate of Augustus; and the assumption of the perpetual dictatorship would hardly by itself suffice to account for the murder of Caesar. But there are signs that in the last six months of his life he aspired not only to a monarchy in name as well as in fact, but also to a divinity which Romans should acknowledge as well as Greeks, Orientals, and barbarians. His statue was set up beside those of the seven kings of Rome, and he adopted the throne of gold, the sceptre of ivory, and the embroidered robe which tradition ascribed to them. He allowed his supporters to suggest the offer of the regal title by putting in circulation an oracle according to which it was destined for a king of Rome to subdue the Parthians, and when at the Lupercalia (Feb. 15, 44 B.C.) Antony set the diadem on his head he rejected the offer half-heartedly on account of the groans of the people. His image was carried in the *Pompa circensis* amongst those of the immortal gods, and his statue set up in the temple of Quirinus with the inscription "To the Unconquerable God." A college of Luperci, with the surname Iuliani, was instituted in his honour and *flamines* were created as priests of his godhead. This was intolerable to the aristocratic republicans, to whom it seemed becoming that victorious commanders should accept divine honours at the hands of Greek and Asiatics, but unpardonable that Romans should offer the same worship to a Roman.

Thus Caesar's work remained unfinished, and this must be borne in mind in considering his record of legislative and administrative reform. Some account of this is given elsewhere (*see* *ROME: History, Ancient*), but it may be well to single out from the list of his measures (some of which, such as the restoration of exiles and the children of proscribed persons, were dictated by political expediency, while others, such as his financial proposals for the relief of debtors and the steps which he took to restore Italian agriculture, were of the nature of palliatives) those which have a permanent significance as indicating his grasp of imperial problems. The Social War had brought to the inhabitants of Italy as far as the Po the privileges of Roman citizenship; it remained to extend this gift to the Transpadane Italians, to establish a uniform system of local administration and to devise representative institutions by which at least some voice in the government of Rome might be permitted to her new citizens. This last conception lay beyond the horizon of Caesar, as of all ancient statesmen; but his first act on gaining control of Italy was to enfranchise the Transpadanes, whose claims he had consistently advocated, and in 45 B.C., he passed the *Lex Iulia Municipalis*, an act of which considerable fragments are inscribed on two bronze tables found at Heraclea near Tarentum.<sup>1</sup> This law deals *inter alia* with the police and the sanitary arrangements of the city of Rome, and hence it has been argued by Mommsen that it was Caesar's intention to reduce Rome to the level of a municipal town. But it is not likely that such was the case. Caesar made no far-reaching modifications in the government of the city, such as were afterwards carried out by Augustus, and the presence in the *Lex Iulia Municipalis* of the clauses referred to may be explained as an example of "tacking" (legislation *per saturam*; *see*, however, note <sup>1</sup> below). The law deals with the constitution of the local senates, for whose members qualifications of age (30 years) and military service are laid down, while persons who have suffered conviction for various specified offences, or who are insolvent, or who carry on discreditable or immoral trades are excluded. It also provides that the local magistrates shall take a census of the citizens at the same time as the census takes place in Rome and send

<sup>1</sup>The statement of Dio and Suetonius, that a *praefectura legum et morum* was conferred on Caesar in 46 B.C. is rejected by Mommsen. It is possible that it may have some foundation in the terms of the law establishing his third dictatorship. According to Dio, the censorship for life was conferred on him in 44 B.C.

<sup>1</sup>Since the discovery of a fragmentary municipal charter at Tarentum dating from a period shortly after the Social War, doubts have been cast on the identification of the tables of Heraclea with Caesar's municipal statute. It has been questioned whether Caesar passed such a law, since the *Lex Iulia Municipalis* mentioned in an inscription of Patavium (Padua) may have been a local charter. The most recent and on the whole the most probable theory is that the tables of Heraclea contain a number of enactments promulgated by Antony after Caesar's death under the law which authorized the ratification of Caesar's "acts" as found in his papers.

the registers to Rome within 60 days. The existing fragments tell us little as to the decentralization of the functions of government, but from the *Lex Rubria*, which applies to the Transpadane districts enfranchised by Caesar (it must be remembered that Cisalpine Gaul remained nominally a province until 42 B.C.) we gather that considerable powers of independent jurisdiction were reserved to the municipal magistrates. But Caesar was not content with framing a uniform system of local government for Italy. He was the first to carry out on a large scale those plans of transmarine colonization whose inception was due to the Gracchi. As consul in 59 B.C. Caesar had established colonies of veterans in Campania under the *Lex Iulia Agraria*, and had even then laid down rules for the foundation of such communities. As dictator he planted numerous colonies both in the eastern and western provinces, notably at Corinth and Carthage. Mommsen interprets this policy as signifying that "the rule of the urban community of Rome over the shores of the Mediterranean was at an end," and says that the first act of the "new Mediterranean state" was "to atone for the two greatest outrages which that urban community had perpetrated on civilization." This, however, cannot be admitted. The sites of Caesar's colonies were selected for their commercial value, and that the citizens of Rome should cease to be rulers of the Mediterranean basin could never have entered into Caesar's mind. The colonists were in many cases veterans who had served under Caesar, in others members of the city proletariat. We possess the charter of the colony planted at Urso in southern Spain under the name of *Colonia Iulia Genetiva Urbanorum*. Of the two latter titles, the first is derived from the name of Venus Genetrix, the ancestress of the Julian house, the second indicates that the colonists were drawn from the *plebs urbana*. Accordingly, we find that free birth is not, as in Italy, a necessary qualification for municipal office. By such foundations Caesar began the extension to the provinces of that Roman civilization which the republic had carried to the bounds of the Italian peninsula. Lack of time alone prevented him from carrying into effect such projects as the piercing of the Isthmus of Corinth, whose object was to promote trade and intercourse throughout the Roman dominions, and we are told that at the time of his death he was contemplating the extension of the empire to its natural frontiers and was about to engage in a war with Parthia with the object of carrying Roman arms to the Euphrates. Above all, he was determined that the empire should be governed in the true sense of the word and no longer exploited by its rulers, and he kept a strict control over the *legati*, who, under the form of military subordination, were responsible to him for the administration of their provinces.

**Writings and Character.**—Caesar's writings are treated under LATIN LITERATURE. It is sufficient here to say that of those preserved to us, the seven books *Commentarii de bello Gallico*, appear to have been written in 51 B.C. and carry the narrative of the Gallic campaigns down to the close of the previous year (the eighth book, written by A. Hirtius, is a supplement relating the events of 51–50 B.C.), while the three books *De bello civili* record the struggle between Caesar and Pompey (49–48 B.C.). Their veracity was impeached in ancient times by Asinius Pollio and has often been called in question by modern critics. The *Gallic War*, though its publication was doubtless timed to impress on the mind of the Roman people the great services rendered by Caesar to Rome, stands the test of criticism as far as it is possible to apply it, and the accuracy of its narrative has never been seriously shaken. The *Civil War*, especially in its opening chapters is, however, not altogether free from traces of misrepresentation. With respect to the first moves made in the struggle and the negotiations for peace at the outset of hostilities, Caesar's account sometimes conflicts with the testimony of Cicero's correspondence or implies movements which cannot be reconciled with geographical facts. We have but few fragments of Caesar's other works, whether political pamphlets such as the *Anticato*, grammatical treatises (*De Analogia*), or poems. All authorities agree in describing him as a consummate orator. Cicero (*Brut.* 22) wrote: *de Caesare ita iudico, illum omnium*

*fere oratorum Latine loqui elegantissime*, while Quintilian (x. 1. 114) says that had he practised at the bar he would have been the only serious rival of Cicero.

The verdict of historians on Caesar has always been coloured by their political sympathies. All have recognized his commanding genius and few have failed to do justice to his personal charm and magnanimity, which almost won the heart of Cicero, who rarely appealed in vain to his clemency. Indeed, he was singularly tolerant of all but intellectual opposition. His private life was not free from scandal, especially in his youth, but it is difficult to believe the worst of the tales which were circulated by his opponents, e.g., as to his relations with Nicomedes of Bithynia. As to his public character, however, no agreement is possible between those who regard Caesarism as a great political creation and those who hold that Caesar by destroying liberty lost a great opportunity and crushed the sense of dignity in mankind. The latter view is unfortunately confirmed by the undoubted fact that Caesar treated with scant respect the historical institutions of Rome, which with their magnificent traditions might still have been the organs of true political life. He increased the number of senators to 900 and introduced provincials into that body; but instead of making it into a grand council of the empire, representative of its various races and nationalities, he treated it with studied contempt, and Cicero writes that his own name had been set down as the proposer of decrees of which he knew nothing, conferring the title of king on potentates of whom he had never heard. A similar treatment was meted out to the ancient magistracies of the republic; and thus began the process by which the emperors undermined the self-respect of their subjects and eventually came to rule over a nation of slaves. Few men, indeed, have partaken as freely of the inspiration of genius as Julius Caesar; few have suffered more disastrously from its illusions. (See further *ROME: History*.)

**BIBLIOGRAPHY.**—The principal ancient authorities for the life of Caesar are his own *Commentaries*, the biographies of Plutarch and Suetonius, letters and speeches of Cicero, the *Catiline* of Sallust, the *Pharsalia* of Lucan, and the histories of Appian, Dio Cassius, and Velleius Paterculus (that of Livy exists only in the *Epitome*). Amongst modern works may be named the exhaustive repertory of fact contained in Drumann, *Geschichte Roms*, vol. iii. (new ed. by Groebe, 1906, pp. 125–829), and the brilliant but partial panegyric of Th. Mommsen in his *History of Rome* (Eng. trans., vol. iv, est. p. 450 ff.). J. A. Froude's *Caesar; A Sketch* (2nd ed., 1896) is equally biased and much less critical. W. Warde Fowler's *Julius Caesar* (1892) gives a favourable account (see also his *Social Life at Rome*, 1909). On the other side see especially A. Holm, *History of Greece* (Eng. trans., vol. iv. p. 582 ff.), J. L. Strachan Davidson, *Cicero* (1894), p. 345 ff. and the introductory lectures in Prof. Tyrrell's edition of the *Correspondence of Cicero*, particularly "Cicero's case against Caesar," vol. v. p. 13 ff. vol. ii. of G. Ferrero's *Greatness and Decline of Rome* (Eng. trans., 1907) is largely devoted to Caesar, but must be used with caution. E. Meyer, *Caesars Monarchie und das Principat des Pompeius* (2nd ed. 1919) and T. Rice Holmes, *The Roman Republic and the founder of the Empire* (1923) are both important. The Gallic campaigns have been treated by Napoleon III., *Histoire de Jules César* (1866), which is valuable as giving the result of excavations, and in English by T. Rice Holmes, *Caesar's Conquest of Gaul* (1901), in which references to earlier literature will be found. A later account is that of G. Veith, *Geschichte der Feldzüge C. Julius Caesars* (1906). For maps see A. von Kampen. For the Civil War see Colonel Stoffel (the collaborator of Napoleon III.), *Histoire de Jules César et la guerre civile* (1887). There is an interesting article, "The Likenesses of Julius Caesar," by J. C. Ropes, in *Scribner's Magazine*, Feb. 1887, with 18 plates. (H. S. J.)

#### MEDIAEVAL LEGENDS

In the middle ages the story of Caesar did not undergo such extraordinary transformations as befell the history of Alexander the Great and the Theban legend. Lucan was regularly read in mediaeval schools, and the general facts of Caesar's life were too well known. He was generally, by a curious error, regarded as the first emperor of Rome,<sup>1</sup> and representing as he did in the popular mind the glory of Rome, by an easy transition he became a pillar of the Church. Thus, in a French pseudo-historic romance *Les Faits des Romains* (c. 1223), he receives the honour of a bishopric. His name was not usually associated with the marvel-

<sup>1</sup>Brunetto Latini, *Trésor*: "Et ainsi Julius César fu li premiers empereur des Romains."

lous, and the *trouvère* of *Huon de Bordeaux* outstepped the usual sober tradition when he made Oberon the son of Julius Caesar and Morgan la Fay. About 1240 Jehan de Tuim composed a prose *Hystore de Julius Cesar* (ed. F. Settegast, Halle, 1881) based on the *Pharsalia* of Lucan, and the *Commentaries* of Caesar (on the Civil War) and his continuators (on the Alexandrine, African, and Spanish wars). The author gives a romantic description of the meeting with Cleopatra, with an interpolated dissertation on *amour courtois* as understood by the *trouvères*. The *Hystore* was turned into verse (alexandrines) by Jacot de Forest (latter part of the 13th century) under the title of *Roman de Julius César*. A prose compilation by an unknown author, *Les Faits des Romains* (c. 1225), has little resemblance to the last two works, although mainly derived from the same sources. It was originally intended to contain a history of the twelve Caesars, but concluded with the murder of the dictator, and in some mss. bears the title of *Li livres de César*. Its popularity is proved by the numerous mss. in which it is preserved and by three separate translations into Italian. A *Mistère de Julius César* is said to have been represented at Amboise in 1500 before Louis XII.

See A. Graf, *Roma nella memoria e nella immaginazione del medio evo*, i. ch. 8 (1882-83); P. Meyer in *Romania*, xiv. (1885), where the *Faits des Romains* is analysed at length; A. Duval in *Histoire littéraire de la France*, xix. (1838); L. Constans in *Petit de Jullevilles' Hist. de la langue et de la litt. française*, i. (1896); H. Wesemann, *Die Cäsarfabeln des Mittelalters* (Löwenberg, 1879).

**CAESAR, SIR JULIUS** (1557?-1636), English judge, descended from the dukes de' Cesarini in Italy, was born near Tottenham in Middlesex. He was educated at Magdalen hall, Oxford, and afterwards at the University of Paris, where in 1581 he was made a doctor of civil law. Two years later he was admitted to the same degree at Oxford, and also became doctor of the canon law. He held many high offices during the reigns of Elizabeth and James I., including a judgeship of the admiralty court (1584), and chancellor and under treasurer of the exchequer (1606). He was knighted by King James in 1603, and in 1614 was appointed master of the rolls, an office which he held till his death on April 18, 1636. He was so remarkable for his charity that it was said of him that he seemed to be the almoner-general of the nation. His manuscripts, many of which are now in the British Museum, were sold by auction in 1757 for over £500.

See E. Lodge, *Life of Sir Julius Caesar* (1810); Wood, *Fasti Oxonienses*, ed. Bliss; Foss, *Lives of the Judges*.

**CAESAREA MAZACA** (mod. *Kaisarieh*), chief town of a vilayet of the same name in Asia Minor. Mazaca, the residence of the kings of Cappadocia, later called *Eusebea* (perhaps after Ariarathes Eusebes), and named *Caesarea* probably by Claudius, stood on a low spur on the north side of Erjies Dag (M. *Argaeus*). The site, now called *Eski-shehr*, shows only a few traces of the old town. It was taken by Tigranes and destroyed by the Persian king Shapur (Sapor) I. after his defeat of Valerian in A.D. 260. In the 4th century Basil, when bishop, established an ecclesiastical centre on the plain, about 1 m. to the north-east, and this gradually supplanted the old town. A portion of Basil's new city was surrounded with strong walls and turned into a fortress by Justinian; and within the walls, rebuilt in the 13th and 16th centuries, lies the greater part of *Kaisarieh*, altitude 3,500 ft. The town was captured by the Seljuk sultan, Alp Arslan, 1064, and by the Mongols, 1243, before passing to the Osmanli Turks. The town is noted for its fruit, especially its vines; it exports tissues, carpets, hides, berries and dried fruit. Pop. (1927) 100,005. It is the headquarters of the American mission in Cappadocia. It is the seat of a Greek bishop, an Armenian archbishop and a Roman Catholic bishop, and there is a Jesuit school.

**CAESAREAN SECTION**, in obstetrics (*q.v.*) the operation for removal of a foetus from the uterus by an abdominal incision, so called from a legend of its employment at the birth of Julius Caesar. This procedure has been practised on the dead mother since very early times; in fact it was prescribed by Roman law that every woman dying in advanced pregnancy should be so treated; and in 1608 the senate of Venice enacted that any prac-

itioner who failed to perform this operation on a pregnant woman supposed to be dead, laid himself open to very heavy penalties. But the first recorded instance of its being performed on a living woman occurred about 1500, when a Swiss pig-gelder operated on his own wife. From this time onwards it was tried in many ways and under many conditions, but almost invariably resulted in death of the mother from sepsis or haemorrhage. Even as recently as the first half of the 19th century the recorded mortality is over 50%. Hence craniotomy—in which the life of the child is sacrificed to save that of the mother—was almost invariably preferred. The introduction of asepsis and use of an improved method of suturing the incised uterine wall have reduced the mortality to so low a point for mother and child that the operation is frequently performed. Where possible, however, induction of premature labour from the seventh month onwards is usually to be preferred.

This operation is now advised for (1) extreme degrees of pelvic contraction, (2) any malformation or tumour of the uterus, cervix or vagina, which would render birth of the child through the natural passages impossible, (3) maternal complications, as eclampsia and concealed accidental haemorrhage, and (4) at the death of the mother for the purpose of saving the child.

**CAESAREA PALESTINAE**, a seaport south of Carmel (mod. *Kaisariyeh*), built (25-13 B.C.) by Herod the Great as port of his capital Sebaste (Samaria) on a Phoenician site known to the ancients as Straton's (Astarte?) Tower. The site with its richly architected structures (palaces, temple, amphitheatre, hippodrome, aqueducts) is described by Josephus (*Antiq.* xv. 9.6.). The harbour "free always from the waves of the sea" was constructed by reinforcing with vast stone blocks two reefs which stretched seawards. A quay encircled the whole harbour on which were arches "where the mariners dwelt." The harbour had a name and fame distinct from the town which, indeed, it partly overshadowed. Caesarea witnessed important events in the lives of Peter, Philip and Paul. It saw the first incidents in the great revolt of the Jews against the Romans (66 A.D.). There Vespasian was proclaimed emperor (69 A.D.). Under Alexander Severus it became the metropolis of Syria and its bishop in consequence the Metropolitan, an office which Eusebius held from 315 to 318. There Procopius was born and there Origen made his home. When the Moslems occupied it in 638 its sea power faded and it rapidly shrank in size and importance. Under the Crusaders it partially revived. They rebuilt and walled a part (about  $\frac{1}{10}$ ) of the Roman city adjacent to the harbour to serve as a citadel. It was taken in 1101 by Baldwin I., on which occasion the "Holy Grail" was discovered, by Saladin (1187), by Richard I. (1191). Louis IX. strengthened its fortifications (1251) and it was finally demolished by Beibars (1265). Stones from the ruins were transported to Acre and Jaffa for building purposes during the 19th century. Turkey transferred thither a small Bosnian community in 1878. Anchorage (10 fathoms) is possible in summer  $\frac{1}{2}$  m. from the shore. At Tell Barak, 6 m. inland, two 2nd century sarcophagi, finely sculptured, were discovered in 1924. They are now in the Jerusalem Museum. See L. Haefeli, *Caesarea am Meer. Topographie und Geschichte der Stadt nach Josephus und Apostelgeschichte* (1923).

**CAESAREA PHILIPPI**, anciently a city (mod. *Banias*), at the southern end of the Hermon range where from a cave issues a source of the Jordan. It was the scene of a great battle in which Palestine was won from the Ptolemies by Antiochus (Polybius, xvi. 18). A village now occupies the site. North of it is the famous "Grotto of the spring," whose well was bottomless (Josephus, *Bell. Jud.* i. 21. 3), and the actions of whose indwelling deity could be affected by casting into the waters a victim (Eusebius, vi. 18). Baal worship was no doubt practised here in early times and its identification with The Baal God of Joshua or the Baal Hermon of I Chronicles is not improbable. Baal gave way to Grecian "Pan and the Nymphs" (inscription in the grotto). The name Paneas (whence *Banias*) was applied to the whole district. Augustus presented the region to Herod who erected a temple to his benefactor and set therein the emperor's image. Philip the Tetrarch enlarged and embellished the town,

naming it Caesarea after Augustus and adding Philippi to distinguish it from the Caesarea (Palestinae) of his father. Agrippa II. to honour Nero changed the name to Neronias, but the name did not endure. Jesus visited the neighbourhood and gave here the great charge to Peter (Mark viii. 27). Here Vespasian refreshed his army with a three weeks' rest before his advance into Galilee. Here, too, Titus after the downfall of Jerusalem held gladiatorial contests on a large scale.

In the 4th cent. Caesarea was erected into an episcopal see. It was taken by the crusaders (1129), the emir of Damascus (1132), and the emir of Aleppo (1137) in a three-cornered contest. It was burned by the Syrians (1157). Some broken columns and carved stones, parts of the old walls and citadel, traces of an aqueduct and some niches in the rock beside the spring are the sole reminders of a vanished glory. A fine mediaeval fortress, dismantled in the 13th cent., stands on a lofty conical hill above the spring.

**CAESARIUS OF ARLES**, SAINT (c. 470–543), bishop of Arles and ecclesiastical legislator, was born at Chalons, Burgundy. In 502 he became bishop of Arles, a town which was then of great commercial and political importance. He convoked the Council of Agde (506), of Arles (524), of Carpentras (527), of Orange and of Vaison (529), and of Marseille (533), wherein such problems as semipelagianism, ecclesiastical jurisdiction and property, and the education and support of the clergy were raised. His works, including his popular sermons, invaluable for history, and his two monastic rules were published in Migne, *Pat. Lat.* vol. lviii.

See Malnory, *St. Césaire Evêque d'Arles* (1894), Arnold, *Caesarius v. Arelate* (Leipzig, 1894); M. Chaillon, *Saint Césaire* (1912); and K. J. Hefele, *Hist. of Councils* (Eng. trans. by W. R. Clark, 1871).

**CAESARIUS OF HEISTERBACH** (c. 1170–c. 1240), German preacher, was born at Cologne, joined the Cistercians and became prior of the Heisterbach house in 1228. Of his best known work, *Dialogue of Visions and Miracles*, a series of ascetical romances, the latest edition is that by J. Strange (Cologne, 1851). Of his remaining works the *Eight Books of Miracles* was edited by Meister (Rome, 1901), the more historical *Life of St. Engelbert* (d. 1225) by Gelenius (1633), the biographical list of archbishops of Cologne between 94–1238 by Cardauns in *Mon. Germ. Hist. Script.* xxiv., his sermons in 1615, and his "*Life of St. Elizabeth of Hungary*" by Huyskens in *Annalen des Historischen Vereins*, etc. (Cologne, 1908).

See Kaufmann, *Caesarius von Heisterbach* (Cologne, 1862); Schönbach, "Studien zur Erzählungslit. des Mittelalters" in *Sitz. der k. Akad. der Wissenschaften*, No. 144 (Vienna, 1902); and E. Beitz, *C. v. Heisterbach und die bildende Kunst* (Augsburg, 1926).

**CAESARIUS OF NAZIANZUS** (c. 330–368), brother of Gregory of Nazianzus, studied at Alexandria and then became a physician. After three years in Constantinople he returned to Nazianzus in 358 and practised at the court of Constantius and of Julian the Apostate. Under the Emperor Valens he became quaestor of Bithynia. The *Dialogues* under his name in Migne's *Patr. Graeca*. 38 are probably spurious.

**CAESIUM**, a metal of the alkali (*q.v.*) group (symbol Cs, atomic number 55, atomic weight 132.81). Its name is derived from the Lat. *caesius*, sky-blue, from two bright blue lines of its spectrum. It was the first metal to be discovered by the aid of the spectroscope (R. Bunsen, *Pogg. Annal.*, cxiii, 337; *Berlin Acad. Ber.*, 1860), although caesium salts had undoubtedly been handled before, but had been mistaken for potassium salts. The most important mineral containing caesium is pollucite, a silicate of aluminium and caesium. This mineral contains from 31%–37% of  $\text{Cs}_2\text{O}$  and occurs in commercial quantities in Maine, U.S.A., and the Isle of Elba. In 1846 C. F. Plattner analysed the mineral and obtained as total constituents 93.75%, reckoning the  $\text{Cs}_2\text{O}$  as  $\text{K}_2\text{O}$ . He was mystified by the result which was cleared up in 1864 by F. Pisani when he found the alkali present to be caesium. Pollucite is attacked quite readily by hydrochloric or nitric acid and after the removal of the silica the caesium may be precipitated by forming the insoluble double chloride with antimony chloride or crystallizing out the fairly insoluble caesium aluminium sulphate, an alum

(*q.v.*). Caesium is found in the mineral springs of Frankenhäusen, Montecatini, in Val di Nievole, Tuscany, and Wheal Clifford, near Redruth, Cornwall, and, associated with rubidium, at Dürkheim; it is also found in lepidolite, leucite, petalite, triphylite and in the carnallite from Stassfurt. The separation of caesium from the minerals which contain it is an exceedingly difficult and laborious process. According to R. Bunsen, the best source of rubidium and caesium salts is the residue left after extraction of lithium salts from lepidolite. This residue consists of sodium, potassium and lithium chlorides, with small quantities of caesium and rubidium chlorides. The caesium and rubidium are separated from this by repeated fractional crystallization of their double platinum chlorides, which are much less soluble in water than those of the other alkali metals. The platinum chlorides are reduced by hydrogen, and the caesium and rubidium chlorides extracted by water. W. Feit and K. Kubierschky (1892) separated rubidium and caesium from the other alkali metals by converting them into double chlorides with stannic chloride; whilst J. Redtenbacher (1865) separated them from potassium by conversion into alums, which are very slightly soluble in a solution of potash alum. In order to separate caesium from rubidium, use is made of the different solubilities of their various salts. The bitartrates  $\text{RbHC}_4\text{H}_4\text{O}_6$  and  $\text{CsHC}_4\text{H}_4\text{O}_6$  have been employed, as have also the alums. The double chloride of caesium and antimony  $3\text{CsCl} \cdot 2\text{SbCl}_3$  has been used, the corresponding compound not being formed by rubidium. The metal has been obtained by electrolysis of a mixture of caesium and barium cyanides, and by heating the hydroxide with magnesium or aluminium. L. Hackspill finds, however, that metallic caesium can be prepared more readily by distilling the chloride with metallic calcium. It is a silvery white metal which burns on being heated in air. It melts at  $26^\circ$  to  $27^\circ$  C and has a specific gravity of 1.88 ( $15^\circ$  C).

*Caesium hydroxide*,  $\text{CsOH}$ , obtained by the decomposition of the sulphate with baryta water, is a greyish-white deliquescent solid which melts at a red heat and absorbs carbon dioxide rapidly. It readily dissolves in water, with evolution of much heat. *Caesium chloride*,  $\text{CsCl}$ , obtained by dissolving the hydroxide or carbonate in hydrochloric acid, forms small cubes which melt at a red heat and volatilize readily; it deliquesces in moist air. The *bromide*,  $\text{CsBr}$ , and *iodide*,  $\text{CsI}$ , resemble the corresponding potassium salts. Many trihaloid salts of caesium are also known such as  $\text{CsBr}_3$ ,  $\text{CsClBr}_2$ ,  $\text{CsBrI}_2$ ,  $\text{CsBr}_2\text{I}$ , etc. (H. L. Wells and S. L. Penfield, 1892). *Caesium sulphate*,  $\text{Cs}_2\text{SO}_4$ , may be prepared by dissolving the hydroxide or carbonate in sulphuric acid. It crystallizes in short hard prisms, readily soluble in water but insoluble in alcohol. It forms caesium alum,  $\text{Cs}_2\text{SO}_4 \cdot \text{Al}_2(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$ . *Caesium nitrate*,  $\text{CsNO}_3$ , is obtained by dissolving the carbonate in nitric acid, and crystallizes in glittering prisms, which melt readily, and when heated evolve oxygen and leave a residue of caesium nitrite. The carbonate,  $\text{Cs}_2\text{CO}_3$ , is soluble in water and in alcohol.

Caesium compounds can be readily recognized by the two bright blue lines (of wave length 4555 and 4593) in their flame spectrum, although these are not present in the spark spectrum. The other lines include three in the green, two in the yellow, and two in the orange. Caesium has an important technical application in the manufacture of radio tubes or "valves." Its nitrate or chloride is mixed with cerium or magnesium and compressed into small tablets which are introduced into the tubes. In evacuating the tubes, these tablets are flashed, helping to secure a high vacuum.

**CAESPITOSE**, a botanical term for "growing in tufts," like many grasses.

**CAESTUS** or **CESTUS**, a gauntlet or boxing-glove used by the ancient pugilists (from Lat. *caedo*, strike). Of this there were several varieties, the simplest and least dangerous being the *melichae* ( $\mu\epsilon\lambda\iota\chi\alpha\iota$ ), which consisted of strips of raw hide tied under the palm, leaving the fingers bare. With these the athletes in the *palaestrae* were wont to practise, reserving for serious contests the more formidable kinds, such as the *sphaerae* ( $\sigma\phi\alpha\iota\rho\alpha\iota$ ), which were sewn with small metal balls covered with leather, and the terrible *murmekes* ( $\mu\acute{\upsilon}\rho\mu\eta\kappa\epsilon\varsigma$ ), sometimes called "limb-breakers" ( $\gamma\upsilon\upsilon\sigma\tau\epsilon\rho\alpha\iota$ ), which were studded

with heavy nails. The straps (*ῥαπτρες*) were of different lengths, many reaching to the elbow, in order to protect the forearm when guarding heavy blows (see J. H. Krause, *Gymnastik und Agonistik der Hellenen*, 1841). The *caestus* is to be distinguished from *cestus* (=embroidered, from *κεντεῖν*), an adjective used as a noun in the sense of "girdle," especially the girdle of Aphrodite, which was supposed to have the power of exciting love.

**CAESURA**, a break within a foot (Gr. *τομή*, cutting) caused by the end of a word, with or without pause in the sense; to be distinguished from a diaeresis (*διαίρεσις*), which is a pause between feet. English examples are:

The proper study ¶ of | mankind | is man (caesura).

And born | to write, || converse, | and live | at ease (diaeresis).

A line will often have many caesuras, as:

arma : vi|rumque : ca|no : Tro|iae : qui | primus : ab| oris

which (as shown) has one in every foot except the sixth; but the term is generally employed of the *principal caesura*; i.e., that in or about the middle of the line, in this case, the one between *cano* and *Troiae*. The parts into which such a caesura divides the verse are called *cola* (*κόλα*, members). Practically every dactylic hexameter and every iambic trimeter has a caesura, the former in the third foot (penthemimeral) or in the second (trithemimeral), usually combined with one in the fourth (hepthemimeral); the latter, in the third or fourth foot. In dactyls a caesura is called *masculine* if it comes after the long syllable, *feminine* if after the first short one (see *VERSE*).

**CAFETERIA.** Cafeterias are popular and up-to-date restaurants which supply meals at the lowest cost by allowing the people using them to wait upon themselves. An institution of American origin and development, the cafeteria has so increasingly fixed itself in public favour that there are now thousands in the United States.

Previous to their introduction there were no restaurants in which a light luncheon could be quickly obtained. Discouraging small orders, restaurant owners did not attract customers who desired little food. Between the high-priced and the general run of restaurants there were few attractive medium-grade eating-places where small quantities of appetizing food could be secured at slight outlay. Most of the so-called moderate-priced restaurants in cities were in cramped quarters, and too frequently their surroundings were as disagreeable as the food was unreliable.

Expected tipping of waiters was a drain upon the resources of large numbers of people working for small pay. The tipping custom became particularly irksome as the cost of living advanced out of all proportion to salaries. With but a short interval for lunch, men and women, girls and boys working in shops and offices also wanted some spare time for themselves in the noon hour. The self-service system did away with all delay. Besides the regular patrons, there is in the large cities a floating population which generally lunches at all hours. The system is practically unknown in Great Britain.

**Origin of the Cafeteria.**—The beginnings were somewhat crude. The Exchange Buffet was established in New York city in 1885. But its system was for men only, and consisted of customers having their orders filled at a central counter and conveying their dishes to other counters, where they ate standing. In 1891, J. R. Thompson opened a restaurant at State and Polk streets, Chicago. It combined the supplying of a variety of hot foods with the self-service plan.

In July, 1925, the *Journal of Home Economics* published the results of a questionnaire it had sent out as to the time and place of the cafeteria's inception. According to the findings, the first convincing demonstration was apparently made in Chicago, and the motive was semi-philanthropic.

Early in the '90s several social and philanthropic organizations in that city conceived the idea of assisting working girls to get cheaper meals by allowing them to wait upon themselves, and eat at tables in a congenial atmosphere. Among these pioneer cafeterias were the Ogontz club in the Pontiac building, the nearby Wildwood club maintained by Miss Kirkland's school, and the Klio Association's Noon-Day Rest, started in 1893 at No. 4

East Monroe street. These places were open only to girl members who paid a small weekly charge for luncheons. The cost was held down by renting an upper floor, by serving smaller portions than customary at the ordinary restaurant and by doing away with the need for waiters. The plan's advantages were perceived by the Young Women's Christian Association, which soon opened cafeterias in Kansas city and in other cities.

**Commercial Value Established.**—The commercial possibilities of the cafeteria idea shortly became evident. Experiments had shown the urgent need of such restaurants for both men and women. Mrs. Knox, one of the first managers of the Noon-Day Rest, opened and successfully managed a cafeteria opposite Marshall Field's department store in Chicago. It was, however, in Los Angeles that the cafeteria's first noted development came. Impressed by the popularity of one of the Chicago clubs, Miss H. S. Mosher, of Michigan, in May 1905, opened a cafeteria in Hill street, Los Angeles. In its first stages, a cigar box was used as a cash register and the other fittings were likewise rudimentary. But these deficiencies were overlooked in the eagerness of crowds to give their patronage where the food could be seen and selected. The novelty made such a sensation that the Los Angeles newspapers commented briskly on the spectacle of citizens balancing trays filled with savoury dishes. More cafeterias were opened in Los Angeles, then the plan spread to San Francisco and rapidly eastward to other cities.

**Its Great Proportions.**—The cafeteria proved so successful that individual concerns expanded increasingly into big corporations. J. R. Thompson's original single restaurant was supplemented by the opening of other restaurants, and in 1916 the John R. Thompson Company was organized. In 1926 it operated 112 restaurants throughout cities in the Middle West, South and East, and in that year served approximately 61,000,000 meals. It has a main commissary in Chicago and a branch commissary in New York city. The Exchange Buffet Corporation in 1926 operated 34 restaurants in New York city and vicinity; its new type of restaurants have the comforts of high-grade restaurants; patrons are allowed to enjoy their meals at tables and the catering is to both men and women. The Waldorf system, which is a consolidation of various concerns, had in 1926 a series of 132 lunch rooms in many New England cities and in some important cities in New York, New Jersey, Pennsylvania and Ohio. The Pig'n Whistle Company in the same year had a chain of 13 high-class restaurants in Pacific coast cities.

The most striking development of the self-service restaurant is that of the Automats, run by the Horn and Hardart Company. The name automat was adopted because the plan, which was first tried out in Germany, provided for dropping nickels in slots, thereby opening a container and releasing the food. From this original idea the company branched to the supplying of hot meals served at counters by attendants and paid for by the requisite coins dropped in slots. In its newer restaurants the automats are a combination of this mode and of the cafeteria, the lower floor devoted to coin machines, the upper to self-service from counters, with payment to a cashier. In 1926 the Horn and Hardart Company was operating 32 automat restaurants in New York city. In addition to the company-operated chains there are many cafeterias owned by individuals and firms or conducted by organizations. There are also co-operative cafeterias.

**Cafeterias in Industrial Plants.**—In their welfare work for employees, beginning generally about the year 1915, many of the great industrial corporations in the United States provided cafeterias in their factories. An investigation made by the U.S. Bureau of Labor Statistics, and published in Bulletin 250 in February 1919, showed that 224 corporations with a total of more than 830,000 employees had installed cafeterias, restaurants or lunch rooms. Of the 112 cafeterias in these establishments, 98 were under company management, a half-dozen were run by contractors and eight by employees. Somewhat more than a fourth of the employees used the cafeterias and restaurants. Since then cafeterias have increased in industrial establishments.

O. Dahl, *Restaurant Management, Principles and Practice* (1927). See also RESTAURANT.

**CAFFEINE**, a vegetable base, present in coffee beans, with the formula  $C_8H_{10}N_4O_2$ . (See PURINES.)

**CAFFIERI, JACQUES** (1678-1755), French worker in metal, the most famous member of a family several of whom distinguished themselves in plastic art, was the fifth son of Philippe Caffieri (1634-1716), a decorative sculptor, who, after serving Pope Alexander VII., entered the service of Louis XIV. in 1660. An elder son of Philippe, François Charles (1667-1721), was associated with him. As a *fondeur ciseleur*, however, the renown of the house centred in Jacques, though it is not always easy to distinguish between his own work and that of his son Philippe (1714-1777). A large proportion of his brilliant achievement as a designer and chaser in bronze and other metals was executed for the crown at Versailles, Fontainebleau, Compiègne, Choisy and La Muette. Jacques and his son Philippe undoubtedly worked together in the "Appartement du Dauphin" at Versailles, where the decorations of the marble chimney-piece in the best type of the Louis XV. style still remain. They also worked together upon the gorgeous bronze case of the famous astronomical clock made by Passemont and Danthiau for Louis XV. between 1749 and 1753. The elder Caffieri was a consummate practitioner of the *style rocaille*, which he redeemed from its mannered conventionalism by the ease and mastery of his treatment. From their studio came an amazing amount of work, chiefly in the shape of those gilded bronze mounts which in the end became more insistent than the pieces of furniture which they adorned. Little of the elder's achievement was ordinary; a large proportion of it is famous. In the Wallace collection (Hertford house, London) is a commode constructed by Gaudreau with mounts from the hand of Jacques Caffieri, in which are seen the brilliance and spontaneity, the sweeping boldness and elegance of line that mark his style at its best. Also at Hertford house is the exceptionally fine lustre which was a wedding present from Louis XV. to Louise Elizabeth of France. After Jacques' death his son Philippe's style was gradually modified into that which prevailed in the third quarter of the 18th century, since by 1777, when he died, the taste for the magnificent mounts of his early days had passed away. Philippe's younger brother, Jean Jacques Caffieri (1725-1792), was a sculptor, but was sufficiently adept in the treatment of metals to design the fine *rampe d'escalier* which still adorns the Palais Royal.

See A. Michel, *À propos de quelques oeuvres de Jean Jacques Caffieri récemment entrées au Musée du Louvre*, in archives of Société de l'Histoire de l'Art français, 4 S. VIII. 251 (1916); F. de Salvarté, *Les ébénistes du XVIII. siècle, leurs oeuvres et leurs marques* (1927).

**CAFTAN** or **KAFTAN**, a tunic or under-dress with long hanging sleeves, tied with a girdle at the waist, worn in the East by persons of both sexes. The caftan was worn by the upper and middle classes in Russia till the time of Peter the Great, when it was generally discarded.

**CAGE**, in mining, a contrivance in which is raised to the surface the "tub," "tram," "hutch" or "box," as the small underground truck or wagon which carries the coal or mineral from the working face to the shaft is called. The cage, which is constructed of steel, is usually of such a capacity as to permit of more than a single tub being drawn to the surface in each wind. The cages are in general use at coal mines; indeed their use is compulsory in Great Britain under Section 40 of the Coal Mines act of 1911, for the raising and lowering of persons at the mine except where there are ladders. At metalliferous mines, the mineral is usually teemed into a storage bin, at the bottom of the shaft or the level, from which it is loaded into a "skip," an iron or steel box running on wheels, which on reaching the surface automatically tips out the ore. But the nature of coal does not permit of such rough usage— from the view of both breakage and dust, it is undesirable.

Prior to the invention of the cage, coal was drawn to the surface in a large wicker-work basket, or "corf." These "corves" were woven of hazel wands. After being filled they were placed on trams which were shoved and pulled by manual labour from the face to the "crane station" where they were lifted on to a horse-trolley, conveyed to the shaft and there separately drawn to the surface by means of the iron bow or handle with which they were fitted. They were unwieldy and required a great deal of repairing; they also imposed a limit on the output. The output of a large colliery as late as 1835 working a twelve hour day, was according to Mr. George Stephenson, 300 tons (1835 *Report*, 1842). This means of conveying coal continued well into the nineteenth century.

**The First Cage.**—During the time this method of raising coal was in vogue the arrangements by which the miners—men and boys—were lowered and raised were also very primitive. Two men would sit each with a leg through a loop of the chain with boys (five or six) clinging to the rope above them. Attempts were made as early as 1816 at Washington colliery in the county of Durham to introduce a better method of raising coal to the surface than by wicker corves, but unsuccessfully. It rested with a mining engineer named T. Y. Hall, in the North of England, to introduce underground in 1833-1834 tubs running on wheels, and their conveyance up the shaft in a cage. Somewhat later he much improved the system by providing wooden *guide rods* in the shaft for the cage, fitted with a *shoe* at the top and bottom, to slide on, and *keeps* or *keps* for the cage to rest on on arrival at the surface whilst the process of changing the tubs (substituting empty for full tubs) was being carried out.

Cages have not undergone much change since they were first introduced, except that they are usually more capacious and carry more and larger tubs, and in most modernly equipped shafts run on steel rope guides—in place of the wooden or steel rail guides, of which there were two to each cage. These ropes, usually four to each cage, are stretched from the top of the pit-head frame and tightened by weights at the bottom of the shaft. At the pit top the guide ropes pass through crossbearers and are held by clamps. By law, guides have to be provided in the case of every working shaft over fifty yards in depth, and in the case of every shaft in course of being sunk over one hundred yards in depth; and every cage has to be provided with catches to prevent tubs falling out; and, when used for raising or lowering persons, has to be covered completely at the top and closed in at the two sides. It also has to be provided with gates or rigid fences and a rigid bar to hold on to.

The attachment of the cage to the winding rope is by means of chains, four or six, one from each corner of the cage and two "idle" chains at the sides; but intervening between the chains and the rope capping or "capel" is a safety or detaching hook—required by law in the case of vertical shafts. If the winding apparatus is used for lowering or raising persons, and in addition, if the shaft is more than 100 yards in depth, the winding engine has to have an automatic contrivance to prevent overwinding. (See WINDING ENGINE.) Every winding rope has to be recapped at intervals of not more than six months, and if used for raising or lowering persons must not be in use for more than three and a half years. All cage chains in general use have to be annealed once at least in every six months, and the detaching hook cleaned and refitted once in every three months. (R. R.)

**CAGLI**, a town and (with Pergola) an episcopal see of the Marches, Italy, in the province of Pesaro and Urbino, 18m. south of the latter town by rail, and 830ft. above sea-level. Pop. (1921) town, 2,888; commune, 12,326. The church of St. Domenico contains a good fresco (Madonna and saints) by Giovanni Santi, the father of Raphael. A tower of the citadel of the 15th century, constructed by Francesco di Giorgio Martini of Siena, is on the south-east of the modern town. Cagli occupies the site of an ancient *vicus* (village) on the Via Flaminia, which bore the name Cale, 24m. north of Helvillum (mod. *Sigillo*) and 18m. S.W. of Forum Sempronii (mod. Fossombrone). Below the town to the north is a single arched bridge of the road, the arch having a span of 15ft. Eight miles north of Cagli the Via

Flaminia, which is still the high-road, traverses the Furlo Pass, with a tunnel 42yd. long, excavated by Vespasian in A.D. 76 or 77, as an inscription at the north end records. There is another tunnel at lower level, which belongs to an earlier date; this seems to have been in use till the construction of the Roman road, which at first ran round the rock on the outside. In repairing the modern road just outside the south entrance to the tunnel, a quantity of debris belonging to the castle of Petra Pertusa, burned by the Lombards in 570 or 571, was found. Here also was found an inscription of A.D. 295, relating to the measures taken to suppress brigandage in these parts. (See APENNINES.)

See *Journal of Roman Studies*, XI., 183 sqq., a brief account with ref. (1921).

**CAGLIARI**, the capital of Sardinia, an archiepiscopal see, and the chief town of a province (see also CARALES). It is 270m. W.S.W. of Naples, and 375m. south of Genoa by sea. Pop. (1921) of town 57,164; of commune, 61,758. It is finely situated at the northern extremity of the Gulf of Cagliari, in the centre of the south coast of the island. The mediaeval town occupies a long narrow hill running north and south, which must have been the ancient acropolis. On each side of the town are lagoons. That of S. Gilla on the west, which produces fish in abundance, was originally an open bay. That of Molentargius on the east has large saltpans which produced 197,000 tons of salt in 1925. The upper town still retains in part its fortifications, including the two great towers at the two extremities, called the Torre dell' Elefante (1307), and the Torre di S. Pancrazio (1305), both erected by the Pisans. On the edge of the cliffs on the east is the cathedral, which was built in 1257-1312 by the Pisans and which retains two of the original transept doors. The pulpit (now divided into two) was brought from Pisa in 1312. The church was, however, remodelled in 1676, and the interior is baroque. The façade, in the baroque style, was added in 1703. The university (400 students) is a little farther north. At the south extremity of the hill, on the site of the bastion of Caterina, a large terrace, the Passeggiata Umberto Primo, has been constructed. Below it are covered promenades, and from it steps descend to the lower town, the oldest part of which (the so-called Marina) slopes gradually towards the sea, while the quarter of Stampace lies to the west, and beyond it again the suburb of Sant'Avendrace. East of the castle hill and the Marina is the quarter of Villanova, which contains the church of S. Saturnino, a domed church of the 8th century with a choir of the Pisan period. The harbour is a good one; the chief exports are lead, zinc and other minerals and salt. The Campidano of Cagliari, the plain which begins at the north end of the lagoon of S. Gilla, is very fertile and much cultivated. The national costumes are rarely now seen in the neighbourhood of Cagliari, except at certain festivals, especially that of S. Efisio (May 1-4) at Pula (see NORA). The methods of cultivation are primitive: the curious water-wheels, made of brushwood with pots tied on to them, and turned by a blindfolded donkey, may be noted. Cagliari is considerably exposed to winds in winter, while in summer it is almost African in climate. The main line of railway runs north to Decimomannu (for Iglesias), Oristano, Macomer and Chilivani (for Terranova and Sassari); while another line (narrow-gauge) runs to Mandas (for Sorgono and Tortoli). There is also a tramway to Quarto S. Elena.

In A.D. 485 the whole of Sardinia was taken by the Vandals from Africa; but in 533 it was retaken by Justinian. In 687 Cagliari rose against the East Roman emperors, under Gialeus, one of the citizens, who made himself king of the whole island, his three brothers becoming governors of Torres (in the north-west), Arborea (in the south-west) and Gallura (in the north-east of the island). The Saracens devastated it in the 8th century, but were driven out, and the island returned to the rule of kings, until they fell in the 10th century, their place being taken by four "judges" of the four provinces, Cagliari, Torres, Arborea and Gallura. In the 12th century Musatto, a Saracen, established himself in Cagliari, but was driven out with the help of the Pisans and Genoese. The Pisans soon acquired the sovereignty over the whole island with the exception of Arborea, which continued to be independent. In 1297 Boniface VIII. invested the kings of

Aragon with Sardinia, and made it the seat of their government. In 1348 the island was devastated by the plague described by Boccaccio. Not until 1403 were the kings of Aragon able to conquer the district of Arborea, which, under the celebrated Eleonora (whose code of laws—the so-called *Carta de Logu*—was famous), offered a heroic resistance. In 1479 the native princes were deprived of all independence. The island remained in the hands of Spain until the peace of Utrecht (1714), by which it was assigned to Austria. In 1720 it was ceded by the latter, in exchange for Sicily, to the duke of Savoy, who assumed the title of king of Sardinia (Cagliari continuing to be the seat of government), and this remained the title of the house of Savoy until 1861. Cagliari was bombarded by the French fleet in 1793, but Napoleon's attempt to take the island failed.

**CAGLIOSTRO, ALESSANDRO**, COUNT (1743-1795), Italian alchemist, and impostor, was born at Palermo. Giuseppe Balsamo (for such was the "count's" real name) fled from Sicily to escape punishment for a series of ingenious crimes, and visited in succession Greece, Egypt, Arabia, Persia, Rhodes (where he took lessons in alchemy and the cognate sciences from the Greek Althotas) and Malta. There he presented himself to the grand master of the Maltese order as Count Cagliostro, and carried favour with him as a fellow alchemist, for the grand master's tastes lay in the same direction. From him he obtained introductions to the great houses of Rome and Naples. At Rome he married Lorenza Feliciani, with whom he travelled, under different names, through many parts of Europe. He visited London and Paris in 1771, selling love-philtres, elixirs of youth, mixtures for making ugly women beautiful, alchemistic powders, etc., and deriving large profits from his trade. After further travels on the Continent he returned to London, where he posed as the founder of a new system of freemasonry, and was well received in the best society, being adored by the ladies. He went to Germany and Holland once more, and to Russia, Poland, and then again to Paris, where, in 1785, he was implicated in the affair of the Diamond Necklace (q.v.); and although Cagliostro escaped conviction by the matchless impudence of his defence, he was imprisoned for other reasons in the Bastille. On his liberation he visited England once more, where he was confined for a while in the Fleet prison. Leaving England, he travelled through Europe as far as Rome, where he was arrested in 1789. He was tried and condemned to death for being a heretic, but the sentence was commuted to perpetual imprisonment, while his wife was immured in a convent. He died in the fortress prison of San Leo.

The famous *Mémoires pour servir à l'histoire du comte de Cagliostro* (1786) are fictitious. The best account of the life, adventures and character of Giuseppe Balsamo is contained in Carlyle's *Miscellanies*. Dumas's novel, *Mémoires of a Physician* is founded on his adventures. See also Sierke, *Schwärmer und Schwindler zu Ende des XVIII. Jahrhunderts* (1875); and the sketch of his life in D. Silvagni's *La Corte e la Società Romana nei secoli XVIII. e XIX.* vol. i. (Florence, 1881).

**CAGNIARD DE LA TOUR, CHARLES** (1777-1859), French engineer and physicist, was born in Paris on March 31, 1777, and after attending the École Polytechnique became one of the *ingénieurs géographiques*. He was made a baron in 1818, and died in Paris on July 5, 1859. He was the author of numerous inventions, including the cagniardelle, a blowing machine, which consists essentially of an Archimedean screw set obliquely in a tank of water in such a way that its lower end is completely, and its upper end partially, immersed, and operated by being rotated in the opposite direction to that required for raising water. In acoustics he invented, about 1819, the improved siren which is known by his name, using it for ascertaining the number of vibrations corresponding to a sound of any particular pitch, and he also made experiments on the mechanism of voice-production. In course of an investigation, in 1822-23, on the effects of heat and pressure on certain liquids, he found that for each there was a certain temperature above which it refused to remain liquid, but passed into the gaseous state, no matter what the amount of pressure to which it was subjected, and in the case of water he determined this critical temperature, with a remarkable approach to accuracy, to be 683.3° F.

**CAGNOLA, LUIGI**, MARCHESE (1762-1833), Italian architect, was born on June 9, 1762, in Milan, and died on Aug. 14, 1833, at Inverigo. He was sent at the age of 14 to the Clementine college at Rome, and afterwards studied law at Pavia. He spent two years in Verona and Venice, studying the architectural structures of these cities. In 1806 he was called upon to erect a triumphal arch at Milan for the marriage of Eugène Beauharnais with the princess of Bavaria. The arch was of wood, but was of such beauty that it was resolved to carry it out in marble. The result was the magnificent Arco della Pace in Milan, surpassed in dimensions only by the Arc de Triomphe in Paris. Among Cagnola's principal works are the Porta di Marengo at Milan, the campanile at Ugnano, and the chapel of Santa Marcellina in Milan.

**CAGOTS**, a people found in the Basque provinces, Béarn, Gascony and Brittany, first mentioned in 1288. In the 16th century they had many names, Cagots, Gahets, Gafets in France; Agotes, Gafos in Spain; and Cacons, Cahets, Caqueux and Caquins in Brittany. During the middle ages they were shunned and hated; were allotted separate quarters in towns, called *cagoteries*, and lived in wretched huts in the country distinct from the villages. Excluded from all political and social rights, they were only allowed to enter a church by a special door, and during the service a rail separated them from the other worshippers. Either they were altogether forbidden to partake of the sacrament, or the holy wafer was handed to them on the end of a stick, while a receptacle for holy water was reserved for their exclusive use. They were compelled to wear a distinctive dress, and so pestilential was their touch considered that it was a crime for them to walk the common road barefooted. The only trades allowed them were those of butcher and carpenter, and their ordinary occupation was wood-cutting. Their language is merely a corrupt form of that spoken around them.

The origin of the Cagots is undecided. Teutonic descent is suggested by their fair complexions and blue eyes. Littré defines them as "a people of the Pyrenees affected with a kind of cretinism." The old mss. call them Chrétiens or Chrestians, and from this it has been argued that they were Visigoths who originally lived as Christians among the Gascon pagans. A far more probable explanation of this name is to be found in the fact that in mediaeval times all lepers were known as *pauperes Christi*, and that these Cagots were affected in the middle ages with a condition closely resembling leprosy. Thus would arise the confusion between Christians and Cretins. To-day their descendants are not more subject to goitre and cretinism than those dwelling around them, and are recognized by tradition and not by features or physical degeneracy. It was not until the French Revolution that any steps were taken to ameliorate their lot, but to-day they have ceased to form a separate class.

See Francisque Michel, *Histoire des races maudites de France et d'Espagne* (1846); *Bulletins de la société anthropologique* (1861, 1867, 1868, 1871); *Annales medico-psychologiques* (Jan. 1867); Paul Raymond, *Moeurs béarnaises* (Pau, 1872); V. de Rochas, *Les Parias de France et d'Espagne* (1877); J. Hack Tuke, *Jour. Anthropological Institute* (vol. ix., 1880).

**CAGUAS** is an important interior town situated on an extensive and fertile plain in the east-central part of Porto Rico. It is about 25m. from San Juan, the principal city and seaport of the island, with which it is connected by a railroad and highways. The population of the town itself, by the 1920 census, was 12,149; in 1930, it was 19,797; the population of the municipal district in 1930 was 47,728.

The town is the centre of a district principally devoted to the production of sugar-cane and tobacco; some fruits and coffee are also produced. There are several important sugar centrals in the district where sugar is manufactured from the cane. In the town there are several cigar factories. The public buildings, stores and shops are attractive. It has a beautiful plaza, well-paved streets, electric lights, water-works and a sewer system. The school buildings are unusually commodious and attractive; the schools, among the best on the island. The municipality has a good hospital and a public library. The town and municipal district are regarded as among the most progressive and prosperous in the island.

**CAHER** (Cahir), market town in a good agricultural district, Co. Tipperary, Ireland, at the foot of the east end of the Galtee mountains on the river Suir, midway between Clonmel and Tipperary on the Gt. Southern Railway. Pop. (1926) 1,707. An ancient fortress on an island in the river was called Dun-iasgach (Fortress abounding in fish). Caher derives from *Cathair*, a stone fortress. The present castle was built (1142) by O'Connor, earl of Thomond. Ardfinnan castle (Norman) stands 6 m. down the Suir; there are stalactite caverns at Mitchelstown 10 m. southwest.

**CAHITA**, a group of North American Indians, mainly of the Mayo and Yaqui tribes, found chiefly in Mexico, belonging to the Piman family, and numbering some 40,000.

**CAHOKIA**, the name of a North American Indian tribe of the Illinois confederacy, and of their mission station, near St. Louis. The "Cahokia mound" there (a model of which is in the Peabody Museum, Cambridge, Mass.) is interesting as the largest prehistoric earthwork in America (see NORTH AMERICA: *Archaeology*).

**CAHOKIA MOUND, THE**. The largest prehistoric American earthwork north of Mexico, one of a group formerly numbering 45 considerable mounds (not including a great number of smaller ones), standing in Illinois, 6 m. east of St. Louis, Mo. The great mound is a quadrangular pyramid 998 by 721 ft., by 99 ft. in height, with a terrace, 30 ft. high, extending outward about 200 ft. from one side and with a width of 500 feet. The area of the base is over 16 acres, and its contents have been estimated at 21,690,000 cu. ft., including the terrace; hence, with the means available to prehistoric Indians, it is estimated that it would have taken 1,000 persons nearly five years to build the main earthwork alone. The mound is named from a tribe which occupied the neighbourhood in historic times.

**CAHORS**, a city of south-western France, capital of the department of Lot, 70m. N. of Toulouse, on the railway to Limoges. Pop. (1926), 10,223. It stands on a rocky peninsula encircled by the river Lot, and is noteworthy alike for its situation, its ancient buildings and its fine old bridge. Before the Roman conquest, Cahors, which grew up near the sacred fountain of Divona (now known as the Fontaine des Chartreux, which provides the town with water), was the capital of the Cadurci. Under the Romans it was famous for its linen cloth. Cahors appears to have had a bishop from the third century. After the fall of the empire it was occupied by the Visigoths and fell later to the Saracens. In the middle ages the town was the capital of Quercy, and its territory until after the Albigensian Crusade was a fief of the counts of Toulouse. The seigniorial rights, including that of coining money, belonged to the bishops. In the 13th century Cahors became a financial centre, owing its importance to a colony of Lombard bankers, and the name *cahorsin* came to signify "banker" or "usurer." Its constant opposition to the bishops drove them, in 1316, to come to an arrangement with the French king, by which the administration of the town was placed almost entirely in the hands of royal officers, king and bishop being co-seigneurs. This arrangement survived till the Revolution. In 1331 Pope John XXII., a native of Cahors, founded there a university, which flourished till 1751, when it was united to its rival, the University of Toulouse. In the 16th century it was a Catholic stronghold and rose against Henry of Navarre who took it by assault in 1580. On his accession Henry IV. punished the town by depriving it of its privileges as a wine-market; the loss of these was the chief cause of its decline.

Cahors is divided into two portions by the Boulevard Gambetta, which runs from the Pont Louis Philippe on the south to the wall of the 14th and 15th centuries enclosing the town on the north. To the east lies the old town, with its dark narrow streets and closely-packed houses; west of the boulevard the new quarter, with spacious squares, stretches to the bank of the river. The Pont Valentré to the west of the town, is the finest mediaeval fortified bridge in France. It dates from 1308 (restored in the 19th century), and is defended at either end by high machicolated towers, another tower, less elaborate, surmounting the centre pier. The cathedral of St. Étienne (1119, but altered between 1285 and

1500) stands in the heart of the old town. Its most remarkable features are the roof of the aisle-less nave, consisting of two round cupolas, and the finely sculptured north portal (c. 1190). Adjoining the church are remains of a cloister (1494-1509). Near the cathedral is St. Urcisse, dating from the 12th and 13th centuries, which preserves Romanesque capitals recarved in the 14th century. Of the palace of Pope John XXII., the great Avignon pope (early 14th century), only a square tower still stands; the rest is in ruins, or unfinished. The residence of the seneschals of Quercy, mainly 14th century, known as the Château du Roi, also remains. The chief of the many old houses of Cahors, is the Maison d'Henri IV. (15th century). The Porte de Diane is a large archway of the Roman period, probably the entrance to the baths. Cahors is the seat of a bishopric, a prefect and a court of assizes. It has tribunals of first instance and of commerce. Tanning, distilling, market-gardening and the preparation of *pâté de fôte gras* and other delicacies are carried on. Wine, nuts, truffles and plums are leading articles of commerce.

**CAIATIA** (mod. *Caiazzo*), an ancient city of Campania, on the right bank of the Volturnus, 11 m. N.E. of Capua, on the road to Telesia. It was already in the hands of the Romans in 306 B.C. In the Social War it rebelled from Rome, and its territory was added to that of Capua by Sulla. In the imperial period, however, we find it once more a *municipium*. Caiatia has remains of "Cyclopean" walls, and under the Piazza del Mercato is a large Roman cistern, which still provides a good water supply. The episcopal see was founded in A.D. 966. The place is frequently confused with Calatia (q.v.).

**CAIETAE PORTUS**, an ancient harbour of *Latium adiectum*, Italy, in the territory of Formiae, from which it is 5 m. S.W. The name (originally *Αἰήτη*) is generally derived from the nurse of Aeneas. The coast of the gulf not only between Caietae Portus and Formiae, but east of the latter also, as far as the modern Monte Scauri, was a favourite summer resort of the Romans (see FORMIAE). After the destruction of Formiae in A.D. 847 it became one of the most important seaports of central Italy (see GAETA). In the town are scanty remains of an amphitheatre and theatre: near the church of La Trinità, higher up, are remains of a large reservoir. There are also traces of an aqueduct. The promontory (548 ft.) is crowned by the tomb of Munatius Plancus, founder of Lugdunum (mod. Lyons), who died after 22 B.C.

**CAILLAUX, JOSEPH MARIE AUGUSTE** (1863- ), French politician, was born March 30, 1863, at Le Mans. His father, Eugène Caillaux, was first a Deputy and later Senator; he was Minister of Public Works from 1873 to 1875 and Minister of Finance in the year 1877.

In 1888, after a brilliant academic career, Joseph Caillaux was admitted to the Ministry of Finance. Later he was appointed lecturer at the École des Sciences Politiques in Paris. In 1898 Caillaux entered the Chamber of Deputies for Mamers, which he continued to represent until 1917. In 1899, Waldeck-Rousseau made him his Minister of Finance. During his three years of office, Caillaux showed not only great financial but also great administrative ability. He inaugurated the reform of the method of taxing alcoholic drinks, the increase in the scale of the inheritance tax and the reform of the sugar laws, thus introducing into French fiscal legislation the progressive policy which characterized his subsequent work. He left office in 1902, but four years later was re-appointed by Clemenceau. During this second term of office he introduced an income tax, the first serious attempt at a just and democratic form of taxation in France.

The Agadir crisis in 1911 marked the next important stage in his career. The Monis Ministry resigned in June and Caillaux was entrusted with the formation of a new ministry, and conducted with signal ability the difficult negotiations with Germany. In 1912, however, he was obliged to retire before the hostility of the Commission of the Senate, appointed to enquire into the Franco-German Treaty. In Nov. 1913 he returned to his former post as Minister of Finance in M. Doumergue's Government. A virulent press campaign was started against him in the *Figaro*, and intimate letters which had passed between M. Caillaux and his wife before their marriage were published. The latter, deeming her honour to

have been assailed, shot the editor, M. Calmette. M. Caillaux was forced to resign, and at the subsequent trial of Madame Caillaux defended her with such force and eloquence that she was acquitted.

On the outbreak of the World War he was appointed paymaster-general to the forces and some months later was entrusted with an economic mission to South America. During his absence he was accused of desiring a premature peace and of caballing in secret against the Government. He returned to France in 1915, however, and entirely ignored the accusations. In July 1917 Clemenceau led the attack upon the Ribot Government and Malvy's administration. The Government was overthrown, and Clemenceau came into power with the one idea to carry on the war, despite all obstacles. His one serious rival was Joseph Caillaux. Clemenceau, therefore, on Dec. 11, 1917, demanded the suspension of Caillaux' parliamentary immunity, moving a vote of no confidence in the Chamber. Caillaux proclaimed his innocence in one of the finest speeches ever made in the Chamber, and demanded to be heard in the Courts. His parliamentary immunity was suspended, and on Jan. 4, 1918, he was arrested. Various cases of high treason were pending at this time and an attempt was made to connect these with the accusations against Caillaux. It was not until Feb. 1920 that he was brought before the Senate, sitting as the High Court of Justice, and indicted for "plotting against the security of the state abroad." After a lengthy debate the accusations fell to the ground one by one. By 213 votes to 28 the arguments of the Procureur-Général, Lescouvé, were refuted. Nevertheless, Caillaux was not completely exonerated. He was condemned to three years' imprisonment, the loss of his civic rights for ten years and to five years' residence within a zone to be indicated by the Government, as well as to pay the costs of the case amounting to about 53,000 francs. The venerable M. Demange, the senior advocate of the court, rose in his seat and said indignantly: "Remember, gentlemen, that you are condemning a man on a count on which he has not been defended." As he had already spent three years in prison Caillaux was released the next morning. He returned to Mamers and devoted his time to writing two books which appeared also in English under the titles of *My Prisons* (1921) and *Whither France? Whither Europe?* (1922).

The amnesty passed by the National Assembly in 1924 restored his political and civic rights to Caillaux. In 1925 he was asked by Painlevé to join his Government as being the one man capable of reducing French finances to order. He accepted the duty and it seemed that at last this difficult task would be accomplished. He attacked first the problem of inter-allied debts. He initiated conversations in London with Churchill and in Washington with the United States Debt Commission. But political considerations proved too strong. He was accused of belonging to the Radical Socialists. Serious friction arose, with the result that Painlevé handed in the resignation of the Government on Oct. 28 and formed a new Ministry, excluding Caillaux. The latter had, in the meantime, been elected Senator and president of the council of the Sarthe. He retired from office with dignity, preferring failure to the countenancing of measures which, in his opinion, would almost certainly prove ruinous to the country. In June 1926, after another cabinet crisis, Caillaux again became Minister of Finance; but his tenure of office was brief. He sought to impose upon France a policy of financial reform—more work, increased production, reduced expenditure—and colonial development; and to suppress occult influences working against the rehabilitation of the franc. His methods, however, were too dictatorial not to arouse Republican resentment and on July 19 the ministry fell on a vote of no confidence passed by the Chamber.

**CAILLAVET, ARMAN DE.** See FLERS, ROBERT DE LA MOTTE-ARGO, MARQUIS DE.

**CAILLETET, LOUIS PAUL** (1832-1913), French ironmaster, was born at Châtillon-sur-Seine on Sept. 21, 1832. He worked in his father's ironworks and later was in charge of the works. He was animated by a love of scientific research. His most important work was on the liquefaction of gases. On Dec. 2, 1877, Cailletet liquefied oxygen at a pressure of 300 atmospheres and at -27° C. The oxygen was obtained in the form of a cloud,

but later he repeated his experiments at the *École Normale* at Paris, when he liquefied hydrogen, nitrogen and air. This work was carried on independently of the work of Pictet on liquefaction and there was considerable discussion as to which of the two had succeeded first.

Cailletet was the author of a number of papers in *Comptes Rendus* and other French scientific periodicals on the liquefaction of gases and the production of low temperatures, on the passage of gases through metals, on manometers for measuring high pressures, on critical points and on the state of matter at low temperatures. He interested himself in aeronautics and devised an apparatus for measuring the height of an aeroplane. Cailletet was a member of the Paris Academy. He died in his native town on Jan. 5, 1913.

**CAILLIÉ** or **CAILLÉ, RENÉ AUGUSTE** (1799–1838), French explorer, was born at Mauzé, Poitou, on Sept. 19, 1799, the son of a baker. His first voyage, made at the age of 16, was to Senegal and Guadeloupe. In 1818 he went from Senegal to Bondu with supplies for a British expedition. In 1824 he was again in Senegal, determined to reach Timbuktu. He spent eight months with the Brakna Moors learning Arabic and being educated as a convert to Islam. Then, dressed as a Mohammedan, and giving out that he was an Arab from Egypt who wished to regain his country, he joined a Mandingo caravan going inland. Starting from Kakundi on the Rio Nunez on April 19, 1827, he travelled east along the hills of Futa Jallon, passing the head stream of the Senegal and crossing the Upper Niger at Kurussa. On reaching Timé in the Kong highlands he was detained five months by illness. In Jan. 1828 he turned north-east and reached Jenné, whence he reached Timbuktu by water. After spending a fortnight (April 20–May 4) in Timbuktu he joined a caravan crossing the Sahara to Morocco, reaching Fez on Aug. 12. From Tangier he returned to France. Major Gordon Laing had reached Timbuktu in 1826, but was murdered on leaving it, and Caillié was the first to achieve the journey in safety, for which he received the prize offered by the Geographical Society of Paris. He received the Order of the Legion of Honour, and his *Journal d'un voyage à Timbuktu et à Jenné dans l'Afrique Centrale* (ed. by E. F. Jomard) was published at public expense in three volumes in 1830. Caillié died at Badère in 1838 of a malady contracted during his travels.

See Dr. Robert Brown's *The Story of Africa*, vol. i. chap. xii. (1892); Goepf and Cordier, *Les Grands Hommes de France, Voyageurs: René Caillié* (1885); E. F. Jomard, *Notice historique sur la vie et les voyages de R. Caillié* (1839). An English version of Caillié's *Journal* was published in London in 1830 in two volumes under the title of *Travels through Central Africa to Timbuctoo etc. Le Tafilet, d'après R. Caillié* (Renseignements Col. Afrique française, 1911).

**CAIN** was, according to Genesis iv. 1, the first-born son of Adam and Eve. The genealogy is interrupted by the story of Cain and Abel (*q.v.*), vv. 2–16, which cannot very well be from the same stratum of tradition as the Garden of Eden story, which precedes, for it implies the existence of a considerable population in the earth (*v.14*). It relates how Cain, a tiller of the ground, enraged because the Lord accepted the offering of his shepherd brother Abel in preference to his own, murdered Abel. For this crime he is cursed and banished from the settled country. Before he departs to the land of Nod (wandering), feeling that in his exile he will be the victim of any man who encounters him, he obtains from the Lord a sign of protection, and a promise that if he be slain despite it he shall be avenged sevenfold. The story is probably intended to explain how a certain tribe, bearing the name of Cain, came to have a certain tattoo mark, and to be noted for the plentiful vengeance it took upon any other tribe by whose hands one of its members was slain. It explains, too, from the point of view of the settled peoples, how this tribe came to live a nomad life. It has been plausibly argued, especially by Eduard Meyer (in *Die Israeliten*) that the tribe in question is the Kenites. The genealogy is resumed in iv. 17–24. In the parallel genealogy from the Priestly Source, Genesis v., the Kenan who appears fourth in the list is probably to be identified with Cain. The representation of Cain as a city-builder accords

ill with the picture of Cain the nomad. Irenaeus mentions a Gnostic sect of the second century called the Cainites, who believed that Cain derived his existence from the superior, Abel from the inferior, power, and that Cain was the first of a line which included Esau, Korah, and the Sodomites; their evangel was a *Gospel of Judas*. (W. L. W.)

**CAINE, SIR THOMAS HENRY HALL** (1853– ), British novelist and dramatist, was born of mixed Manx and Cumberland parentage at Runcorn, Cheshire, on May 14, 1853. He was educated with a view to becoming an architect, but turned to journalism, becoming a leader-writer on the *Liverpool Mercury*. He went to London at the suggestion of D. G. Rossetti, with whom he had had some correspondence, and lived with the poet for some time before his death. He published a volume of *Recollections of Rossetti* (1882), and also some critical work; but in 1885 he began an extremely successful career as a novelist of a melodramatic type with *The Shadow of a Crime*, followed by *The Son of Hagar* (1886), *The Deemster* (1887), *The Bondman* (1890), *The Scapegoat* (1891), *The Manxman* (1894), *The Christian* (1897), *The Eternal City* (1901), and *The Prodigal Son* (1904). His writings on Manx subjects were acknowledged by his election in 1901 to represent Ramsey in the House of Keys. *The Deemster*, *The Manxman* and *The Christian* had already been produced in dramatic form, when *The Eternal City* was produced with magnificent accessories by Beerbohm Tree in 1902, and in 1905 *The Prodigal Son* had a successful run at Drury Lane. Among his later works a notable novel was *The Woman of Knockaloe* (1923). He was recipient of the K.B.E. in 1918 for his services in the World War, during which he was concerned with British propaganda in the United States, and in 1922 was made a Companion of Honour.

See C. F. Kenyon, *Hall Caine; The Man and the Novelist* (1901); and the novelist's autobiography, *My Story* (1908).

**CAINOZOIC**, more correctly **KAINOZOIC**, often written **CENOZOIC** in America (from the Gr. *καίνο*, recent, *ζωή*, life); in geology, the name given to the youngest of the three great eras of geological time, the other two being the Mesozoic and Palaeozoic eras. It is equivalent to **TERTIARY** (*q.v.*).

**ÇA IRA**, a song of the French Revolution, with the refrain:

Ah! ça ira, ça ira, ça ira!  
Les aristocrates à la lanterne.

The words, written by one Ladré, a street singer, were put to an older tune, called "Le Carillon National," and the song rivalled the "Carmagnole" (*q.v.*) during the Terror. It was forbidden by the Directory.

**CAIRD, EDWARD** (1835–1908), British philosopher and theologian, brother of John Caird (*q.v.*), was born at Greenock on March 22, 1835, and educated at Glasgow university and Balliol college, Oxford. He took a first class in moderations in 1862 and in *Literae humaniores* in 1863, and was Pusey and Ellerton scholar in 1861. From 1864 to 1866 he was fellow and tutor of Merton college. In 1866 he became professor of moral philosophy in the University of Glasgow, and in 1893 succeeded Jowett as master of Balliol. With T. H. Green he founded in England a school of orthodox neo-Hegelianism, and exerted a far-reaching influence on English philosophy and theology. Owing to failing health he gave up his lectures in 1904, and in May 1906 resigned his mastership. He died on Nov. 1, 1908.

His publications include *Philosophy of Kant* (1878); *Critical Philosophy of Kant* (1889); *Religion and Social Philosophy of Comte* (1885); *Essays on Literature and Philosophy* (1892); *Evolution of Religion* (Gifford Lectures, 1891–92); *Evolution of Theology in the Greek Philosophers* (1904).

For a criticism of Dr. Caird's theology, see A. W. Benn, *English Rationalism in the 19th Century* (1906); Sir Henry Jones and J. H. Muirhead, *The Life and Philosophy of Edward Caird* (1921).

**CAIRD, JOHN** (1820–1898), Scottish divine and philosopher, was born at Greenock on Dec. 15, 1820, and died July 30, 1898. He was educated at Glasgow university, ordained in the Church of Scotland in 1845, and became professor of Divinity at Glasgow in 1862. In 1873 he was appointed vice-chancellor and principal of Glasgow university. His *Introduction to the Philosophy of Reli-*

*gion* (1880) is a reproduction of Hegelian teaching. His argument for the Being of God is based on the hypothesis that thought—not individual but universal—is the reality of all things, the existence of this Infinite Thought being demonstrated by the limitations of finite thought. Again his Gifford Lectures (1892-93 and 1895-96) are devoted to the proof of the truth of Christianity. Caird wrote also an excellent study of Spinoza, relating his doctrines to those of Hegel.

**CAIRN**, a heap of stones piled up in a conical form. In modern times cairns are often erected as landmarks; in ancient times they were erected as sepulchral monuments. Burial-cairns are either long or round, corresponding with long barrows and round barrows of earth. Meetings of the tribes were held at them, and the inauguration of a new chief took place on the cairn of one of his predecessors. Thus, in 1225, the O'Connor was inaugurated on the cairn of Fraech, the son of Fiodhach of the red hair. In mediaeval times cairns are often referred to as boundary marks. In Highland districts small cairns used to be erected at places where the coffin of a distinguished person was "rested" on its way to the churchyard. Memorial cairns are still occasionally erected; e.g., the cairn raised in memory of the Prince Consort at Balmoral. (See BARROW.)

**CAIRNES, JOHN ELLIOTT** (1823-1875), British political economist of the classical school, was born at Castle Bellingham, Co. Louth, Ireland, and educated at Trinity college, Dublin. He then studied law, and was called to the Irish bar. But he had little taste for the practice of law, and devoted himself to the study of political economy, and to journalism mainly on Irish social and economic questions. In 1856, through the influence of Archbishop Whateley, he was elected Whateley professor of political economy at Trinity college, Dublin. The lectures delivered in 1856 were published as *The Character and Logical Method of Political Economy*.

In 1861 Cairnes was appointed professor of political economy and jurisprudence at Queen's college, Galway, and in 1866 professor of political economy at University college, London. His health was already seriously undermined when he came to London, and he resigned in 1872. He died at Blackheath, London, on July 8, 1875.

The principal works of Prof. Cairnes, in addition to those already mentioned, were: *The Slave Power* (1862), in which he expounded the inherent disadvantages of slave labour, and gave a well-founded forecast of the probable issue of the struggle in America which influenced in a marked degree serious opinion in England on the case for the North; *Political Essays* (1873), containing his papers on Irish questions, especially on the educational system; and his largest work, *Some Principles of Political Economy, Newly Expounded* (1874). This last work does not profess to be a complete treatise; in it Cairnes expands and discusses the theories of value, cost of production, wages, labour and capital, international value, as laid down in the works of Smith, Ricardo and Mill. While Cairnes was generally in agreement with Mill, he analysed his propositions in a way which was often destructive.

Cairnes's principal contributions to the science of economies were his exposition of the province and method of political economy, his analysis of the cost of production in relation to value, his theory of the limitations imposed by the division of classes on free competition, and his defence and development of the wages fund doctrine after it had been abandoned by Mill. He regarded political economy as a science, and therefore neutral in its results with regard to social facts or systems. He was an economist of the theoretical school, and opposed those who desired to treat political economy as an integral part of social philosophy, and those who, like Jevons, sought to express economic facts in quantitative formulae. In his day he held an authority second only to that of Mill.

**CAIRNGORM**, a yellow or brown variety of quartz, named from Cairngorm or Cairngorum, one of the peaks of the Grampian mountains in Banffshire, Scotland. According to E. H. Cunningham-Craig, the mineral occurs in crystals lining cavities in highly-inclined veins of a fine-grained granite running through the coarser granite of the main mass. Shallow pits were formerly dug in the

kaolinized granite for sake of the cairngorm, and the mineral was also found as pebbles in the bed of the river Avon. Cairngorm is a favourite ornamental stone in Scotland and is used in brooches worn with Highland costume.

**CAIRNS, HUGH McCALMONT CAIRNS**, 1st EARL (1819-1885), Irish statesman, and lord chancellor of England, was born at Cultra, Co. Down, Ireland, on Dec. 27, 1819, and was educated at Belfast academy and Trinity college, Dublin, graduating with a senior moderatorship in classics in 1838. In 1844 he was called to the bar at the Middle Temple, to which he had migrated from Lincoln's Inn. During his first years at the chancery bar, Cairns showed little promise of the eloquence which afterwards distinguished him. In 1852 he entered parliament as member for Belfast, and his Inn, on his becoming a Q.C. in 1856, made him a bencher.

In 1858 Cairns was appointed solicitor-general, and was knighted, and in May of that year made two of his most brilliant and best-remembered speeches in the House of Commons. In the first he defended Lord Ellenborough's public censure of Lord Canning in the India despatch, and in the other he spoke in reply to Lord John Russell for the Government—the Reform bill—winning the most cordial appreciation from Disraeli. In 1866, when Lord Derby returned to office, he was made attorney-general and in the same year after a breakdown in health he became a Lord Justice of Appeal. At first unable to accept a peerage for want of means, he was enabled to do so in 1867 by the assistance of a relative.

The appointment of Baron Cairns of Garmoyle as lord chancellor in 1868 involved the superseding of Lord Chelmsford, an act which apparently was carried out by Disraeli with less tact than might have been expected of him. Disraeli held office on this occasion for a few months only, and when Lord Derby died in 1869, Lord Cairns became the leader of the Conservative opposition in the House of Lords. He had distinguished himself in the Commons by his resistance to the Roman Catholics' Oath bill brought in in 1865; in the Lords, his efforts on behalf of the Irish Church were equally strenuous. His speech on Gladstone's Suspensory bill was afterwards published as a pamphlet, but the attitude which he and the peers who followed him had taken up, in insisting on their amendments to the preamble of the bill, was one difficult to maintain, and when Lord Cairns was privately offered concessions provided he withdrew his opposition at once, he took the responsibility of accepting, as there was no opportunity to consult his party. Not long after this, Lord Cairns resigned the leadership of his party in the upper house, but he had to resume it in 1870 and took a strong part in opposing the Irish Land Bill in that year. On the Conservatives coming into power in 1874, he again became lord chancellor; in 1878 he was made Viscount Garmoyle and Earl Cairns; and in 1880 his party went out of office.

After this, owing to failing health, his appearances were less frequent, and he died at Bournemouth from congestion of the lungs on April 2, 1885. Cairns was the first lawyer of his time. His judgments were in the main expositions of principle, with a few decisions cited at the end as illustrations. In the legislation of the day, particularly on questions involving the Church or legal reform, his influence was great, and the harmony with which he could work with his great friend and opponent, Lord Selborne, led to this influence being felt while he was in opposition as well as when he was in office. Among the Statutes with which he was concerned were the Conveyancing Act 1881-82, the Settled Land Act, the Judicature Acts, and the Married Women's Property Act. Of his speeches, in addition to those referred to above, his criticism of Gladstone's policy in the Transvaal after Majuba (*Times*, April 1, 1881) is especially memorable.

Martin, *The Life of the Prince Consort* (1875-80); Lord Malmesbury, *Memoirs of an ex-Minister* (1884); E. Manson, *Builders of our Law*, 2nd ed. (1904); J. B. Atlay, *Victorian Chancellors*, vol. ii (1906-08).

**CAIRNS, JOHN** (1818-1892), Scottish Presbyterian divine, was born at Ayton Hill, Berwickshire, on Aug. 23, 1818, the son of a shepherd. He went to school at Ayton and Oldcambus, Berwickshire, and managed with some difficulty to support himself at Edinburgh university, where he became the most distinguished student of his time, graduating M.A. in 1841, first in classics and philosophy and bracketed first in mathematics. In May 1876 he was appointed joint professor of systematic theology and apologetics with James Harper, principal of the United Presbyterian Theological college, whom he succeeded as principal in 1879. He died on March 12, 1892, at Edinburgh.

Among his principal publications are *An Examination of Ferrier's "Knowing and Being,"* and *the Scottish Philosophy* (a work which gave him the reputation of being an independent Hamiltonian in philosophy); *Memoir of John Brown, D.D.* (1860); *Romanism and Rationalism* (1863); *Outlines of Apologetical Theology* (1867); *The Doctrine of the Presbyterian Church* (1876); *Unbelief in the 18th Century* (1881); *Doctrinal Principles of the United Presbyterian Church* (Dr. Blair's Manual, 1888).

See MacEwen, *Life and Letters of John Cairns* (1895); *John Cairns; Principal Cairns* (Famous Scot series, 1896).

**CAIRNS**, a port on Trinity bay on the north-east coast of Queensland stretched along the narrow lowland strip which intervenes between the Atherton plateau (1,000-4,000 ft.) and the sea. The hinterland comprises an important agricultural and sugar-growing area, with considerable possibilities for the further development of tropical fruit culture (bananas, pineapples), tropical agriculture generally, dairying, etc. The climate is tropical (mean ann. temps. 82°-68°; av. ann. rainfall 90.5 in., falling mainly in Dec.-April), and the seaward portions of the highlands are heavily clad with forests ("brush") yielding useful timber. The rocks of the Atherton highlands—Palaeozoic sediments largely metamorphosed by granitic and later igneous intrusives—are highly mineralized and Cairns is the outlet for numerous fields producing silver-lead, copper (Chillagoe, etc.) and tin (Herberton) and other minerals. The output (1925-26) was valued at c. £300,000. The needs of the mines and their railways lend additional importance to the Mt. Mulligan coal-field. The town has three sugar-mills, saw-mills, a (meat) freezing works, etc., and is the centre of a well-developed tram and railway system—both Government and private (mineral and sugar) lines—the many branches of which tap the mining areas and penetrate as far as Forsyth (Etheridge gold-field). The wild and heavily forested hills, the Barron river with gorge and falls, possess great scenic attractions and Cairns is growing in popularity as a tourist centre. Connection by rail (Great North Coast line) exists with all the chief eastern towns and with Brisbane (1,040 m.). The harbour is excellent and is regularly visited by coasting lines (1925-26: 586,000 tons entered). The total trade (1926-27) was valued at £1,227,000, exports consisting mainly of sugar, metals, maize, beef. The population was (1926) 9,000 and is increasing.

**CAIRO**, the capital of modern Egypt and the most populous city in Africa, on the Nile, 12m. S. of the apex of the Delta, in 30° 3' N. and 31° 21' E. It is 130m. S.E. of Alexandria, and 148m. W. of Suez by rail, though only 84m. from the last-named port by the overland route across the desert, in use before the opening of the Suez canal. Cairo occupies a length of 5m. on the east bank of the Nile, stretching north from the old Roman fortress of Babylon, and covers about 8 sq.m. It is built partly on the alluvial plain of the Nile valley and partly on the rocky slopes of the Mokattam hills, which rise 550ft. above the town.

The citadel, on a spur of the Mokattam hills, occupies the south-east angle of the city; the prospect from the ramparts is strikingly picturesque. Below lies the city with its ancient walls and lofty towers, its gardens and squares, its palaces and its mosques, with their delicately-carved domes and minarets covered with fantastic tracery, the broad river studded with islands, the valley of the Nile dotted with groups of trees, with the pyramids on the south horizon, and on the east the barren cliffs, backed by a waste of sand. The newer quarters of Cairo, situated near the river, are laid out in the fashion of French cities, but mediaeval Cairo can still be seen in scores of narrow, tortuous streets and busy bazaars in the eastern parts of the town.

**Principal Quarters and Modern Buildings.**—From the citadel a straight road runs north to the Ezbekia gardens, which form the central point of the foreign colony. About half a mile north of the gardens is the Central railway station, approached by a broad road. The Arab city and the quarters of the Copts and Jews lie east of the two streets named. West of them lies the port or riverside district, with the arsenal, foundry and railway

BY COURTESY OF THE NEAR EAST RELIEF  
CAIRENE FAMILY OF LOWER CLASS  
IN NATIVE COSTUME

works, a paper manufactory and the Government printing press, founded by Mohammed Ali. A little distance south-east of the Ezbekia is the Place Atabeh, the chief point of intersection of the electric tramways. From the Place Atabeh a narrow street, the Muski, with its continuation, the rue Neuve, leads east into the heart of the Arab city. Another street leads south-west to the Nile, at the point where the Kasr-en-Nil or Great Nile bridge spans the river, leading to Gezira, a large island with Ismail's palace, now turned into a hotel, polo, cricket and tennis grounds and a racecourse. Yet another street, running due south, leads to the Abdin square; and in the far south, opposite old Cairo, across a narrow arm of the river, lies Roda island, where a progressive housing policy has been carried out by the municipality.

The Government offices and other modern public buildings, as well as the European residential quarters, are nearly all in the western half of the city. On the south side of the Ezbekia are the post office, the courts of the Mixed Tribunals, and the opera house. On the east side are the bourse and the Crédit Lyonnais, on the north the buildings of the American Mission. On or near the west side of the gardens are most of the larger European hotels. Facing the river immediately north of the Great Nile bridge are the large barracks, called Kasr-en-Nil, and the fine Egyptian museum. South of the bridge are the Ismailia palace (a royal residence), the British residency, and other buildings. Farther removed from the river are the offices of the ministries of public works and of war—a large building surrounded by gardens—and of justice and finance. On the east side of Abdin square is Abdin palace, an unpretentious building used for official receptions. Adjoining the palace are barracks. North-east of Abdin square, in the Sharia Mehemet Ali, is the Arab museum and khedivial library. In Shari Dawarrin are the new Houses of Parliament.

**The Oriental City.**—The eastern half of Cairo is divided into many quarters. These quarters were formerly closed at night by massive gates, of which a few remain. In addition to the Mohammedan quarters, usually called after the trade of the inhabitants or some notable building, there are the Copt or Christian quarter, the Jews' quarter, and the old "Frank" quarter in the Muski district where, since the days of Saladin, "Frank" merchants have been permitted to live and trade. Some of the principal European shops are still to be found in this street. The Copt and Jewish quarters lie north of the Muski. The modern Coptic cathedral, dedicated to St. Mark, is in the basilica style. The oldest Coptic church in Cairo is, probably, the Keniset-el-Adra, or church of the Virgin, which is stated to preserve the original type of Coptic basilica. In the Copt quarter are also Armenian, Syrian, Maronite, Greek and Roman Catholic churches. In the Arab city the streets as a rule are winding and narrow; but fine *sebils* or public fountains abound, and the houses of the wealthier citizens are picturesque and ample. They are built generally round an open courtyard, in a style of elaborate arabesque, the windows shaded with projecting cornices of graceful woodwork (*mushre-*

*biya*) and ornamented with stained glass. The principal apartment is often paved with marble; in the centre a decorated lantern is suspended over a fountain, while round the sides are richly inlaid cabinets and windows of stained glass; and in a recess is the *divan*, a low, narrow, cushioned seat. The lower storey is generally built of the soft calcareous stone of the neighbouring hills, and the upper storey, which contains the harem, of painted brick. The shops of the merchants are small and open to the street. The greater part of the trade is done, however, in the bazaars or markets, which are held in large *khans* or storehouses, of two storeys and of considerable size. Access to them is gained from the narrow lanes which usually surround them. The khans often possess fine gateways. The principal bazaar, the Khan-el-Khalil, marks the site of the tombs of the Fatimite caliphs.

**The Citadel and the Mosques.**—Besides the citadel, the principal edifices in the Arab quarters are the mosques and the ancient gates. The citadel or El-Kala was built by Saladin about 1166, and now contains a palace and a mosque of Oriental alabaster erected by Mohammed Ali. The dome and the two slender minarets of this mosque are among the most picturesque features of Cairo. In the centre is a well called Joseph's Well, sunk in the solid rock to the level of the Nile. There are four other mosques within the citadel walls, the chief being that which was built in A.D. 1317 by Sultan Nasir ibn Kalaun, recently renovated. The upper parts of the minarets are covered with green tiles, and crowned by bulbous cupolas. Adjoining the citadel is the mosque of Sultan Hasan, one of the finest in the city. It dates from A.D. 1357, and is celebrated for the grandeur of its porch and cornice and the delicate stalactite vaulting which adorns them. Isolated from the others, the oldest mosque in the city is that of Tulun (c. A.D. 879) exhibiting very ancient specimens of the pointed arch. Near the west end of the Khan-el-Khalil lie the mosque, the ruined hospital and the tomb of Kalaun, a group of buildings in a style resembling the contemporaneous mediaeval work in Europe, with pointed arches in several orders. At the east end of the Khan-el-Khalil is the mosque of El Hasanēn, which is invested with peculiar sanctity as containing relics of Hosain and Hasan, grandsons of the Prophet. But to foreigners the most interesting of all is the mosque el-Azhar, founded in the 10th century and immediately converted into a university. And the chief theological seminary of the Islamic world it still remains, with 12,000 students from all Muslim lands. Its influence on orthodox Mohammedan sentiment and policy is waning, but is yet unique. In all, Cairo contains over 260 mosques, and nearly as many *zawias* or chapels. Of the gates the finest are the Bab-en-Nasr, in the north wall of the city, and the Bab-*ez-Zuwēla*, the only surviving part of the southern fortifications.

**Tombs of the Caliphs and Mamelukes.**—Beyond the eastern wall of the city are the splendid, but decaying, mausolea erroneously known to Europeans as the tombs of the caliphs; they really are tombs of the Circassian or Burji Mamelukes, a race extinguished by Mohammed Ali. The chief tomb mosques are those of Kait Bey, the finest of its kind in Egypt; of el-Ashraf Burshey and of Sultan Barkuk, with two domes and two minarets, completed A.D. 1410. South of the citadel is another group of tomb-mosques known as the tombs of the Mamelukes. They are architecturally of less interest than those of the "caliphs." South-west of the Mameluke tombs is the much-venerated tomb-mosque of the Imam esh-Shaf'i, founder of one of the four orthodox sects of Islam; and close to it lies the family burial-place of the reigning family.

**Old Cairo and Babylon.**—South of the present city lie the mounds of the earlier Fostat. But the most important part of Old Cairo is the walled Roman fortress of Babylon. Several towers of this fortress remain, and in the south wall is a massive gateway, uncovered in 1901. The Nile once flowed under it, and from very early days it has been inhabited by a Christian colony. It now contains five Coptic churches, a Greek convent and two churches and a synagogue. The principal Coptic Church is that of Abu Serga (St. Sergius). The crypt dates from about the 6th century and is dedicated to Sitt Miriam (the Lady Mary), from a tradition that in the flight into Egypt the Virgin and Child

rested at this spot. The wall above the high altar is faced with beautiful mosaics of marbles, blue glass and mother-of-pearl. Of the other churches in Babylon the most noteworthy is that of El Adra (the Virgin), also called El Moallaka, or The Suspended, being built in one of the towers of the Roman gateway. The other buildings in Old Cairo, or among the mounds of rubbish which adjoin it, include several fort-like *ders* or convents.

Opposite Old Cairo lies the island of Roda, where, according to Arab tradition, Pharaoh's daughter found Moses in the bulrushes. It contains a mosque built by Kait Bey, and at its southern extremity is the Nilometer, by which the Cairenes have for over a thousand years measured the rise of the river. It is a square well with an octagonal pillar marked in cubits in the centre.

**Northern and Western Suburbs.**—Two miles north-east of Cairo and on the edge of the desert is the suburb of Abbasia (named after the viceroy Abbas), with the military barracks where Arabi Pasha surrendered to the British on Sept. 14, 1882, the day after the battle of Tel el-Kebir. Mataria, a village 3m. farther to the north-east, is the site of the defeat of the Mamelukes by the Turks in 1517, and of the defeat of the Turks by the French under Gen. Kléber in 1800. At Mataria was a sycamore-tree, the successor of a tree which decayed in 1665, venerated as being that beneath which the Holy Family rested on their flight into Egypt. Less than a mile north-east of Mataria are the scanty remains of the ancient city of On or Heliopolis, with a fine obelisk, about 66ft. high, erected by Useratesen I. of the XIIth dynasty. A perfectly equipped residential suburb is named Heliopolis, and adjoining it is a large aerodrome, which is the chief air station in North Africa.

On the west bank of the Nile, opposite the southern end of Roda island, is the small town of Giza or Gizeh, a fortified place of considerable importance in the times of the Mamelukes. The grounds of this palace have been converted into zoological gardens. A broad, tree-bordered, macadamized road, along which run electric trams, leads south-south-west across the plain to the Pyramids of Giza, 5m. distant, built on the edge of the desert.

**Inhabitants.**—The inhabitants of Cairo are of many diverse races, the various nationalities being frequently distinguishable by differences in dress as well as in physiognomy and colour. The Cairenes, or native citizens, differ from the fellahin in having a much larger mixture of Arab blood, and are at once keener witted and more conservative than the peasantry. The Arabic spoken by the middle and higher classes is generally inferior in grammatical correctness and pronunciation to that of the Bedouins of Arabia, but is purer than that of Syria or the dialect spoken by the Western Arabs. Besides the Cairenes proper, who are largely engaged in trade or handicrafts, the inhabitants include Arabs, numbers of Nubians and Negroes—mostly labourers or domestics in nominal slavery—and many Levantines, there being considerable colonies of Syrians and Armenians. The higher classes of native society are largely of Turkish or semi-Turkish descent. Of other races the most numerous are Greeks, Italians, British, French and Jews. Bedouins from the desert frequent the bazaars.

At the beginning of the 19th century the population was estimated at about 200,000; in 1882 it had risen to 374,000; and in 1925 it was over 850,000, including more than 80,000 foreigners.

**Climate and Health.**—In consequence of its insanitary condition, Cairo used to have a heavy death-rate. Since the British occupation in 1882 much has been done to better this state of things, notably by a good water-supply and a proper system of drainage. New suburbs have been laid out, new bridges thrown across the Nile, and a progressive housing policy established. The hospitals have been cleaned and modernized: and a fine new ophthalmic laboratory has been built at Giza, as a gift by the British in memory of Egyptians who lost their lives in the World War. The climate in winter is dry, healthy and often cold: in summer it is hot and stifling; and though the rainfall is negligible, exhalations from the river, especially when the flood has begun to subside, render the districts near the Nile damp during September, October and November.

**Commerce.**—The commerce of Cairo, of considerable extent and variety, consists mainly in the transit of goods. Gum, ivory,

#### CAIRO TO-DAY

1. The mosque of Ahmed Ibn Tulun (built about A.D. 879), showing the first use in Egypt of the pointed arch
2. An arched street, showing in the distance the mosque of El Azhar, the chief theological seminary of Islam
3. The mosque of Mohammed Ali in the citadel of Cairo. This mosque is built of Oriental alabaster
4. A gateway of the citadel. The citadel (El Kala) was erected by Saladin about A.D. 1106

hides and ostrich feathers from the Sudan, cotton, sugar and grain from Upper Egypt, indigo and shawls from India and Persia, sheep and tobacco from Asiatic Turkey, and European manufactures, such as machinery, hardware, cutlery, glass and cotton and woollen goods, are the more important articles. The traffic in slaves ceased in 1877. The local industries include cotton factories, paper mills and a sugar refinery. Silk goods, saltpetre, gunpowder, leather, and a number of other products, are also manufactured.

**Mohammedan Architecture.**—Architecturally considered Cairo is still the most remarkable and characteristic of Arab cities. The outstanding feature of its architecture is its extraordinary freedom from restraint, shown in the wonderful variety of its forms, and the skill in design which has made the most intricate details to harmonize with grand outlines. Here the student may best learn the history of Arab art. Like its contemporary Gothic, it has three great periods, those of growth, maturity and decline. Of the first, the mosque of Ahmed Ibn-Tulun and the three great gates of the city, the Bab-en-Nasr, Bab-el-Futuh and Bab-Zuwela, are splendid examples. The design of these entrance gateways is extremely simple and massive, depending for their effect on the fine ashlar masonry in which they are built, the decoration being more or less confined to ornamental disks. The mosque of Tulun was built entirely in brick, and is the earliest instance of the employment of the pointed arch in Egypt. The curve of the arch turns in slightly below the springing, giving a horse-shoe shape. The stucco facing of the brick walls led to the enrichment of the archivolt and imposts with that peculiar type of conventional foliage which characterizes Mohammedan work, and which in this case was carried out by Coptic craftsmen. The second period passes to a luxuriance promising decay, as instanced in the mosque of Sultan Hasan, below the citadel, those of Muayyad and Kalaun, with the Barkukiya and the mosque of Barkuk in the cemetery of Kait Bey. The simple plain ashlar masonry still predominates, but the wall surface is broken up with sunk panels, sometimes with geometrical patterns in them. The principal characteristics of this second period are the magnificent portals, rising sometimes, as in the mosque of Sultan Hasan, to 80 or 90 ft., with elaborate stalactite vaulting at the top, and the deep stalactite cornices which crown the summit of the building. The decoration of the interior consists of the casing of the walls with marble with enriched borders, and (about 20 ft. above the ground) friezes 3 to 5 ft. in height in which the precepts of the Koran are carved in relief, with a background of conventional foliage. Of the age of decline the finest monument is the mosque of Mohammed Bey Abu-Dahab.

After centuries of neglect efforts are now made to preserve the monuments of Arabic art, a commission with that object having been appointed in 1881; while a law of 1918 extended protection to all buildings dating from the Arab conquest to the reign of Mohammed Ali. Thus the Tulun mosque was saved, Coptic churches are being cared for, and important excavations have been made in the Roman fortress at Babylon.

**Museums and Library.**—The museum of Egyptian antiquities was founded at Bulak in 1863, being then housed in a mosque, by the French savant Auguste Mariette. In 1889 the collection was transferred to the Giza palace, and in 1902 was removed to its present quarters, erected at a cost of over £250,000. A statue of Mariette was unveiled in 1904. The museum is mainly devoted to antiquities of Pharaonic times, and, except in historical papyri, in which it is excelled by the British Museum, is the most valuable collection of such antiquities in existence.

The Arab museum and royal library are housed in a building erected for the purpose, at a cost of £66,000, and opened in 1903. In the museum are preserved treasures of Saracenic art, including many objects removed from the mosques for their better security. The royal library contains over 100,000 volumes, one-half being books and mss. in Arabic, Persian, Turkish, Amharic and Syriac. The Arabic section includes a unique collection of korans. The Persian section is rich in illuminated mss. The numismatic collection, as regards the period of the caliphs and later dynasties, is one of the richest in the world.

**History.**—Before the Arab conquest of Egypt the site of Cairo appears to have been open country. Memphis was some 12 m. higher up on the opposite side of the Nile, and Heliopolis was 5 or 6 m. distant on the north-east. The most ancient known settlement in the immediate neighbourhood of the present city was the town called Babylon, which is said by Strabo to have been founded by emigrants from the ancient city of the same name in 525 B.C., *i.e.*, at the time of the Persian conquest of Egypt. Here the Romans built a fortress and made it the headquarters of one of the three legions which garrisoned the country. Amr, the conqueror of Egypt for the caliph Omar, after taking the town besieged the fortress for the greater part of a year, the garrison surrendering in April A.D. 641. The town of Babylon disappeared, but the strong walls of the fortress in part remain.

Cairo itself is the fourth Mohammedan capital of Egypt; the site of one of those that had preceded it is, for the most part, included within its walls, while the other two were a little to the south. Amr founded El-Fostât, the oldest of these, close to the fortress which he had besieged. Fostât signifies "the tent," and the town thus built where Amr had pitched his tent is to-day, with the Roman town which preceded it, represented by Masr el-Atika, or "Old Cairo." Shortly after the overthrow of the Omayyad dynasty, and the establishment of the Abbasids, the city of El-'Askar was founded (A.D. 750) by Suleimân, the general who subjugated the country, and became the capital and the residence of the successive lieutenants of the Abbasid caliphs. Its site is now entirely desolate. The third capital, El-Katai, was founded about A.D. 873 by Ahmed Ibn Tulun, as his capital. It continued the royal residence of his successors but was sacked not long after the fall of the dynasty and rapidly decayed. A part of the present Cairo occupies its site and contains its great mosque, that of Ahmed Ibn Tulun.

Jauhar (Göhar) el-Kaid, the conqueror of Egypt for the Fatimite caliph El-Moizz, founded a new capital, A.D. 968, which was named El-Kähira, that is, "the Victorious," a name corrupted into Cairo. In A.D. 1176 Cairo was unsuccessfully attacked by the crusaders; shortly afterwards Saladin built the citadel on the lowest point of the mountains to the east, which immediately overlooked El-Katai, and he partly walled round the towns and large gardens within the space now called Cairo. Under the prosperous rule of the Mameluke sultans this great tract was filled with habitations; a large suburb to the north, the Hoseynia, was added: and the town of Bulak was founded. After the Turkish conquest (A.D. 1517) the metropolis decayed, but its limits were the same. In 1798 the city was captured by the French, who were driven out in 1801 by the Turkish and British forces, the city being handed over to the Turks. Mohammed Ali, originally the Turkish viceroy, by his massacre of the Mamelukes in 1811, in a narrow street leading to the citadel, made himself master of the country, and Cairo again became the capital of a virtually independent kingdom. Under Mohammed and his successors all the western part of the city has grown up. In 1882 Cairo was occupied by the British, and its subsequent history is merged in that of Egypt generally.

**CAIRO** (kā'rō), a city in the southern tip of Illinois, U.S.A., on the Mississippi river at the mouth of the Ohio, 150 m. S.E. of St. Louis; the county seat of Alexander county. It is on Federal highways 51 and 60; and is served by the Illinois Central, the Mobile and Ohio, the Big Four, the Missouri Pacific, and the St. Louis South-western railways, by ferries across both rivers, and by the Federal barge line and other steamers on both rivers. The population in 1920 was 15,203, of whom 5,000 were negroes, and was 13,532 in 1930 by the Federal census. The city is built on a tongue of land between the rivers, protected by great levees which withstood even the flood of 1927, when the Mississippi rose to 58 ft. and the Ohio to 56-4 ft. Its fine situation and transportation facilities make it an important shipping and transshipping centre, not only for fertile southern Illinois (popularly called "Egypt") but for the entire Mississippi valley and far distant ports. The city's jobbing business amounts to \$15,000,000 a year. There are various manufacturing industries (including flour, lumber, veneer and articles made of wood), with an output in 1925 valued at

\$7,210,861. At Mound City, 5m. N., is a national cemetery, containing 5,532 graves.

After abortive attempts in 1818 and in 1835, a successful settlement was made here in 1851-54, under the auspices of the New York Trust Company. The Illinois Central Railroad was opened in 1856, and the city was chartered in 1857. During the Civil War it was an important strategic point, and was a military centre and depot of supplies for the Federal armies in the West. At Mound City Admiral Andrew H. Foote in 1862 established a naval depot for the base of his operations on the Mississippi. Cairo is said to be the "Eden" of Charles Dickens's *Martin Chuzzlewit*.

**CAIROLI, BENEDETTO** (1825-1889), Italian statesman, was born in Pavia on Jan. 28, 1825. From 1848 until the completion of Italian unity in 1870, his whole activity was devoted to the Risorgimento, as Garibaldian officer, political refugee, anti-Austrian conspirator and deputy to parliament. In 1870 he conducted the negotiations with Bismarck, during which the German chancellor is alleged to have promised Italy possession of Rome and of her natural frontiers if the Democratic Party could prevent an alliance between Victor Emmanuel and Napoleon. When in 1876 the Left came into power, Cairoli became parliamentary leader of his party, and, after the fall of Depretis, Nicotera and Crispi, formed his first cabinet in March 1878 with a Franco-phil and Irredentist policy. General irritation was caused by his and Count Corti's policy of "clean hands" at the Berlin Congress, where Italy obtained nothing, while Austria-Hungary secured a European mandate to occupy Bosnia and the Hercegovina. The attempt of Passanante to assassinate King Humbert at Naples (Dec. 12, 1878) caused Cairoli's downfall in spite of the fact that he himself was wounded. On July 3, 1879, Cairoli returned to power, and in the following November formed with Depretis a coalition ministry, in which he retained the premiership and the Foreign Office. Confidence in French assurances, and belief that Great Britain would never permit the extension of French influence in North Africa, prevented him from foreseeing the French occupation of Tunis (May 11, 1881). In view of popular indignation he resigned. He died on Aug. 8, 1889.

See S. Cardillo Brigandi, *Benedetto Cairoli nella storia d'Italia* (1881).

**CAISSON**, when employed as a military term, denotes an ammunition wagon or chest; in architecture, a sunk panel or coffer in a ceiling, or in the soffit of an arch or a vault. In civil engineering, the word is used in connection with a variety of hydraulic works. An early use is as an equivalent of *camel*; a floating airtight tank, formerly constructed of timber but now always of steel, capable of being sunk to the required depth by the admission of water, which is afterwards pumped out or evacuated by air pressure, thus imparting additional buoyancy to any craft to which it may be secured. This contrivance is the prototype of the pontoon and of the floating-dock (*q.v.*). It is employed, in various forms, in connection with salvage operations. See SALVAGING.

More commonly *caisson* implies a case or enclosure employed for keeping out water during the construction of foundations and other works in water-bearing strata, at the side of or under rivers and in the sea bed. There are three general types of caisson construction:—

(1) Box caissons, employed when no sinking operation through strata is required, are open at the top and closed at the bottom. The sides of the caisson, when it is sunk in position on a prepared bed, emerge above the water-level, and it serves as a shell for the building of a foundation. Such caissons are built of timber (especially in America), of steel, and of reinforced concrete or of combinations of these materials. They are often employed in building the solid superstructures of rubble mound breakwaters (*q.v.*); and, since about 1905, reinforced concrete caissons have been used in the construction of quay walls. In a few cases, *e.g.* at Dublin, they have been sunk on a dredged and levelled natural bottom, but more usually are founded on a prepared bed of rubble stone or concrete as at Marseille. When sunk and filled with concrete these large boxes form monolithic masses, often considerably exceeding 1,000 tons in weight (see Dock). A large dry dock at Le Havre, opened in 1927, was built in and upon a steel box

caisson framework, which was floated into position over the site of the dock, previously dredged to the required depth, and there sunk in place.

(2) Open caissons. One variety, employed for bridge foundations when little or no sinking through strata is required, is open at bottom and top and has no cutting edge. Caissons of this description, made of iron plates, were used for some of the foundation piers of the Forth bridge. Timber caissons are frequently employed in America. Another form used for sinking through strata is provided with a cutting edge at the bottom. Rectangular iron plate caissons of this description were employed in constructing the foundations of the Tower bridge, London. Cylinder caissons, consisting of a shell of masonry, concrete, wood, steel or reinforced concrete, or of composite construction, and provided with some form of cutting edge, are commonly employed for bridge (*q.v.*) foundations and in sinking shafts in alluvial strata. They are sunk to the required depth by excavating the material within the cylinder and at the same time weighting it, or using a water-jet to assist the sinking process. The internal space is, after sinking, filled with masonry or concrete. The open "well" foundations of brickwork, used for centuries in India, and the concrete well monoliths (see Dock), widely used in dock construction, and sometimes for the foundations of bridge piers, are, strictly speaking, open caissons. The monoliths are built up in tiers on a steel cutting edge or curb and have two or more open vertical wells within which excavation is carried on by grab dredging or other means.

(3) Compressed-air caissons. Where foundations have to be carried down to a considerable depth in soft, water-bearing strata, such as running sand, or where hard material is met with, which cannot be readily excavated by the means permissible in open caisson working, the use of compressed air is often resorted to. Compressed-air working can in some cases, when necessary, be applied to the sinking of caissons, started by the open method, by the addition of the necessary airtight floor, air locks and shafts. The method of compressed-air sinking consists essentially in the provision of an airtight floor in the caisson, at a height which provides room for a working chamber between it and the cutting edge, in which men can work under compressed air and carry on the necessary excavation. A shaft and air lock afford access and exit for men and materials; and the air pressure is varied in accordance with the head of water. Compressed-air caissons are employed not only for bridge foundations but in the construction of quay walls and foundations of other structures in water-bearing strata. Movable compressed-air caissons, which, after the lowest portions of the foundations have been laid, are raised by screw jacks and moved into position for constructing the next section, have been used in some instances for bridge pier foundations and dock construction.

Floating, sliding and rolling caissons built of steel are often employed for closing dry-dock entrances. They are also used, but less frequently, in place of hinged gates at the entrances to locks and docks (*q.v.*).

See C. E. Fowler, *Sub-Aqueous Foundations* (3rd ed. 1914); H. S. Jacoby and R. P. Davis, *Foundations of Bridges and Buildings* (1925). (N. G. G.)

**CAISSON DISEASE**, a group of morbid changes met with in caisson workers and divers in diving dress. In order to exclude water, air pressure within a caisson used for subaqueous works must be increased by one atmosphere, or 15 lb. per sq. in. for every 33½ ft. that the caisson is submerged below the surface. Hence at a depth of 100 ft. a worker in a caisson, or a diver in a diving-dress, must be subjected to a pressure of 60 lb. per sq. in. A similar condition obtains when caissons are used on land for driving tunnels. Exposure to such pressures is apt to be followed by symptoms of a very varied character, including pains in the muscles and joints (the "bends"), deafness, embarrassed breathing, vomiting, paralysis ("divers' palsy"), fainting and sometimes even sudden death. At the St. Louis bridge, where a pressure was employed equal to 4½ atmospheres, out of 600 workmen, 119 were affected and 14 died. Symptoms do not appear while the pressure is being raised nor so long as it is continued,

but only after it has been removed; they are due to effervescence of gases absorbed in the body-fluids during exposure to pressure. Experiment has proved that in animals exposed to compressed air nitrogen is dissolved in the fluids in accordance with Dalton's law, to the extent of roughly 1% for each atmosphere of pressure, and also that when the pressure is suddenly relieved the gas is liberated in bubbles throughout the body. Set free in the spinal cord, for instance, they may give rise to partial paralysis, in the labyrinth of the ear to auditory vertigo, or in the heart to stoppage of the circulation. But if the pressure is relieved gradually they are not formed, because the gas comes out of solution slowly and is removed by the lungs. To prevent caisson disease, therefore, the decompression should be slow; Leonard Hill suggests it should be at a rate of not less than 20 minutes for each atmosphere of pressure. Good ventilation of the caisson is also of great importance and long shifts should be avoided, because by fatigue the circulatory and respiratory organs are rendered less able to eliminate the absorbed gas and because a high partial pressure of oxygen acts as a general protoplasmic poison. It has been found that liability to caisson disease increases with age. Hence healthy young men alone should be employed. If the slightest symptom occurs on decompression the sufferer should be re-compressed, and then decompressed more slowly.

See Paul Bert, *La Pression barométrique* (1878); and Leonard Hill, *Recent Advances in Physiology and Biochemistry* (1906), (both these works contain bibliographies); Mummery, *British Medical Journal*, June 27th, 1908; *Diseases of Occupation*, by T. Oliver (1908); *Diseases of Workmen*, by T. Luson and R. Hyde (1908).

**CAITHNESS**, a county occupying the extreme north-east of Scotland, bounded west and south by Sutherlandshire, east by the North Sea, and north by the Pentland Firth. Its area (excluding water) is 438,833 acres. The formation is mainly middle Old Red Sandstone, and the surface consists of barren moors, almost destitute of trees. It slopes from the north and east up to a belt of metamorphic rocks in the south and west, where the chief mountains are Morven (2,313 ft.), Scaraben (2,054 ft.) and Maiden Pap (1,587 ft.). Morven is a shapely peak of sandstones and conglomerates on a platform of quartzose rocks. The principal rivers are the Thurso ("Thor's River"), rising in Cnoc Crom Uillt (1,199 ft.) near the Sutherlandshire border, and reaching the sea in Thurso Bay; the Forss, which, emerging from Loch Shurrery, enters the sea at Crosskirk, a fine cascade about a mile from its mouth giving the river its name (*fos*, Scandinavian, "waterfall"; in English the form is *force*); and Wick Water, which, draining Loch Watten, flows into the sea at Wick. Small lochs are numerous, the largest being Loch Watten, 2½ m. by ¾ m., and Loch Calder, 2¼ by 1 m. So much of the land is flat and boggy that there are no glens, except in the mountainous south-west, although towards the centre of the county are Strathmore and Strathbeg (the great and little valleys). Most of the coastline is precipitous; Dunnet Head (346 ft.) is the most northerly point of Scotland. From Berriedale at frequent intervals round the coast occur "stacks" or detached pillars of red sandstone.

Caithness is separated from the Orkneys by the Pentland Firth, a strait about 14 miles long and from 6 to 8 miles broad. The tidal wave races at a speed which varies from 6 to 12 m. an hour. At the meeting of the western and eastern currents the waves at times rise into the air like a waterspout. The breakers caused by the sunken reefs off Duncansbay Head create the Bores of Duncansbay, and eddies off St. John's Point are the origin of the Merry Men of Mey, while off the island of Stroma occurs the whirlpool of the Swalchie, and off the Orcadian Swona is the vortex of the Wells of Swona. Nevertheless, as the most direct road from Scandinavian ports to the Atlantic the Firth is used by many vessels. In the eastern entrance to the Firth lies the group of islands known as the Pentland Skerries. On Muckle Skerry, the largest, stands a lighthouse with twin towers, 100 ft. apart. The island of Stroma (pop. 277) also belongs to Caithness.

**History.**—Picts' houses, Norse names and Danish mounds attest that these peoples displaced each other in turn, and the number and strength of old fortified keeps point to long periods of unrest. There are a few circles of standing stones, as at Stemster Loch and Bower, and ruins of Roman Catholic chapels

and places of pilgrimage occur in almost every district. The most important remains are those of Bucholie Castle, Girnigo Castle, and the tower of Keiss; and, on the south-east coast, the castles of Clyth, Swiney, Forse, Laveron, Knockinnon, Berriedale, Achastle and Dunbeath, the last of which is finely situated on a detached stack of sandstone rock. About six miles from Thurso stand the ruins of Braal Castle, the residence of the ancient bishops of Caithness. On the coast of the Pentland Firth, 1½ miles west of Duncansbay Head, is the site of John o' Groat's house.

**Agriculture.**—Only about two-fifths of the arable land, forming a broad belt along the coast, is good, and about half the county consists of rough moor, sparsely inhabited, used for grazing, and rich in game. In spite of this poverty and a damp and windy climate, progressive landlords and tenants keep a considerable part of the acreage of large farms successfully tilled. In 1824 James Traill of Ratter, near Dunnet, recognizing that it was impossible to expect tenants to reclaim and improve the land on a system of short leases, advocated large holdings on long terms, so that farmers might enjoy a substantial return on their capital and labour. Oats and turnips are the chief crops. Sheep—chiefly Leicester and Cheviots—of which the wool is in especial request in consequence of its fine quality, cattle, horses and pigs are raised for southern markets.

**Other Industries.**—The great source of profit to the inhabitants is to be found in the fisheries for cod, haddock, etc., and herring. The last is the most important, particularly in summer, the centre of operations being at Wick. The fisheries give employment to a large number of coopers, curers, packers and helpers. The salmon fisheries on the coast and in the rivers are valuable. The Thurso is one of the best salmon streams in the north. Of manufacture there is little beyond tweeds, nets and ropes, and whisky, with saw-milling, all at Wick. Caithness flagstones have long been quarried for paving. The London, Midland and Scottish railway crosses the shire in a rough semicircle from a point near Altnabreac via Halkirk, to Wick, with a branch from George-mas Junction to Thurso, and a light line from Wick to Lybster. Road motor services radiate from Wick. There is communication by steamer between Wick and Thurso and the Orkneys and Shetlands, Aberdeen and Leith.

**Population and Government.**—The population of Caithness in 1921 was 28,284, and in 1931 25,656, of whom 633 spoke Gaelic and English. The only burghs are Wick (pop. in 1931 7,548) and Thurso (2,946). The county returns one member to parliament with Sutherland, and unites with Orkney and Shetland, to form a sheriffdom. There is a resident sheriff-substitute at Wick, who sits also at Thurso and Lybster.

**CAIUS** or **GAIUS**, pope from 283 to 296, was the son of Gaius, or of Concordius, a relative of the emperor Diocletian, and became pope on Dec. 17, 283. His tomb, with the original epitaph, was discovered in the cemetery of Calixtus and in it the ring with which he used to seal his letters (*see* Arringhi, *Roma Subterr.*, l. iv. ch. xlviii. p. 426). He died in 296.

**CAIUS** (*Anglice*, KEES, KEYS, etc.), **JOHN** (1510–1573), English physician, and second founder of the present Gonville and Caius college, Cambridge, was born at Norwich, Oct. 6, 1510. He was admitted a student at what was then Gonville hall, Cambridge, where he seems to have studied divinity. In 1533 he visited Italy, where he studied under the celebrated Montanus and Vesalius at Padua, taking his degree in physic in 1541. After an extended tour in Europe, he practised in London, being for some years president of the College of Physicians. In 1557 he enlarged the foundation of his old college, named it "Gonville and Caius college," and endowed it with several considerable estates. In Jan. 1559 he accepted the mastership of the college, an office which he held until a month before his death on July 29, 1573. By obtaining a grant in 1564 for the college to have annually the bodies of two malefactors for dissection, Dr. Caius became a pioneer in advancing the study of anatomy.

His works, together with the *Memoir* by John Venn, have been edited by E. S. Roberts (1912).

**CAJAMARCA**, a department of Peru lying between the western and central Cordilleras and extending from the frontier

of Ecuador south to about 7° S. lat., having the departments of Piura and Lambayeque on the west and Amazonas on the east. Its area according to official returns is 12,541 square miles. The upper Marañón traverses from the eastern boundary of the department. The department is an elevated region, well watered with a large number of small streams which eventually find their way through the Amazon into the Atlantic. Many of its products are of the temperate zone, and considerable attention is given to cattle-raising. Coal is found in the province of Hualgayoc, which is also one of the rich silver-mining districts of Peru. Next to its capital the most important town of the entire department is Cajamarquilla.

**CAJAMARCA** or **CAXAMARCA**, a city of northern Peru, capital of a department and province of the same name, 90m. E. by N. of Pacasmayo, its port on the Pacific coast. The population of the city is estimated at 13,000. It is situated in an elevated valley between the central and western Cordilleras, 9,400ft. above sea-level, and on the Eriznejás, a small tributary of the Marañón. The streets are wide and cross at right angles; the houses are generally low and built of clay. Among the notable public buildings are the old parish church built at the expense of Charles II. of Spain, the church of San Antonio, a Franciscan monastery, a nunnery and the remains of the palace of Atahualpa, the Inca ruler whom Pizarro treacherously captured and executed in this place in 1533. The hot sulphur springs of Pultamarca, called the Baños del Inca (Inca's baths), are a short distance east of the city and are still frequented. Cajamarca is an important commercial and manufacturing town, being the distributing centre for a large inland region and having long-established manufactures of woollen and linen goods, and of metal-work, leather, etc. It is the seat of one of the seven superior courts of the republic, and is connected with the coast by telegraph and telephone. A railway has been undertaken from Pacasmayo, on the coast, to Cajamarca, and has been completed to Chileté, 84m. from the coast.

**CAJATAMBO** or **CAXATAMBO**, a town and province of the department of Ancachs, Peru, on the western slope of the Andes. It has a population of about 5,000. The town is 110m. N. by E. of Lima, in 9° 53' S., 76° 57' west. The principal industries of the province are the raising of cattle and sheep and the cultivation of cereals. Cochineal is a product of this region. Near the town there are silver mines, in which a part of its population is employed.

**CAJEPUT OIL**, a volatile oil obtained by distillation from the leaves of the myrtaceous tree *Melaleuca Leucodendron*. The trees yielding the oil are found throughout the Indian Archipelago, the Malay Peninsula and over the hotter parts of the Australian continent; but the greater portion of the oil comes from Celebes. The oil is prepared from leaves which are macerated in water, and distilled after fermenting for a night. It is extremely pungent and has the odour of a mixture of turpentine and camphor. It consists mainly of cineol (*see* TERPENES), from which cajuputene having a hyacinthine odour can be obtained by distillation with phosphorus pentoxide. The drug is a typical volatile oil, and is used internally in doses of  $\frac{1}{2}$  to 3 minims, for the same purposes as, say, clove oil. It is frequently employed externally as a counter-irritant.

**CAJETAN** (GAETANUS), CARDINAL (1468–1534), was born at Gaeta in the kingdom of Naples. His proper name was Tommaso de Vio, but he adopted that of Cajetan from his birthplace. When 16 he became a Dominican, and in 1493 received his B.A. from Padua, where he was subsequently professor of metaphysics. In 1508 he was made general of his order, and for his defence of the papal claims against the Council of Pisa (1511) Leo X. made him a cardinal and archbishop of Palermo in 1517. The year following he went as legate to Germany, to quiet the commotions raised by Luther. It was before him that the Reformer appeared at the diet of Augsburg; and it was he who, in 1519, helped in drawing up the bull excommunicating Luther. In April 1519 he was made bishop of Gaeta. Among other negotiations, Cajetan was able to secure the election of Adrian VI. in 1521–22. Nominated by Clement VII. a member of the committee of cardinals appointed to report on the "Nuremberg Recess," he recom-

mended, in opposition to the majority, certain concessions to the Lutherans, notably the marriage of the clergy, as in the Greek Church, and communion in both kinds according to the decision of the council of Basel. He died on Aug. 9, 1534.

Cajetan was a zealous Thomist but reflects the humanism and the controversies against Averroism and Scotism which he had encountered at Padua. He wrote commentaries upon Aristotle's *Categories*, *Post. An.*, *De Anima* and upon the *Summa* and *De Ente et Essentia* of Aquinas and also many opuscula. These have passed through a number of editions, the important commentary on the *Summa* being adjoined to the Leonine edition of Aquinas.

*See* Mandonnet, in *Dict. of Cath. Theol.* (1904); and T. M. Lindsay, *History of the Reformation*, vol. i. (1906).

**CAKCHIQUEL**, a group of Indians living in the highlands of Guatemala. Their tongue, one of the "metropolitan" Maya dialects, is spoken in the Departments of Sololá, Chimaltenango, Sacatepéquez, and Escuintla. They number about 130,000 souls.

The history of the Cakchiquel, like that of the Quiché (*q.v.*), is preserved in a manuscript written shortly after the Spanish conquest. It relates the history of the creation and their wanderings from the mysterious Tulan where all the Maya tribes once lived. It describes their varying fortunes in the almost constant wars they waged with their neighbours after settling on the shores of Lake Atitlan in Guatemala. Upon the arrival of the Spaniards (1524) the Cakchiquel made no resistance, partly through fear of Spanish arms and partly through unwillingness to ally themselves with their Quiché enemies. Hence Alvarado and his army were received in peace and the first European settlement in the country resulted. The following year, however, the Cakchiquel revolted and were defeated by the Spaniards. Like the other highland Indians, the Cakchiquel were agriculturists, who lived in cities of stone strongly fortified, on inaccessible mountain ridges. Their capital, Iximché, was particularly impregnable, as the surviving remains testify to-day. Written books, the Maya calendar, and other higher arts enjoyed by the more advanced people of Middle America were known to the Cakchiquel. A curious feature of their government was the succession of kings. This post they allotted to two families who assumed the triple canopy of State in rotation.

To-day the Cakchiquel, like their neighbours, are largely engaged in agricultural pursuits, for the most part as peons on the coffee estates. They still retain their costumes of native cotton covered with embroidery which differ from village to village. They perform various dances, sometimes of a pagan nature, but, living closer to the capital than some of the other Indians, they have been forced to assume more ostensibly Christian ways.

*See* Domingo Juarros, *History of the Kingdom of Guatemala* (1823); D. G. Brinton, ed., *Annals of the Cakchiquels* (Philadelphia, 1885).

**CAKE-BREAKER:** *see* FARM MACHINERY.

**CAKES AND CAKE-MAKING.** The following general rules must be observed in the making of cakes: Make up the fire so that the oven is the right heat when the cake is ready. When cooking by gas or electricity make the oven hot 15 minutes before the cake is put in, then lower heat. For large cakes, after they have risen and set, lower heat yet again. Small cakes, buns, etc., require a fairly hot oven and should cook in from 10 to 20 minutes. Large cakes require a moderate oven and heavy fruit cakes take from 2½ to 3 hours to cook. After the cake has browned a greased paper should be placed over it while the inside bakes. To ascertain if a cake is done insert a skewer gently into the centre, if it comes out clean the cake is ready.

**Preparation of Tins.**—Grease inside of tin, then dust all over with equal quantities of cornflour and icing sugar which have been sieved together several times. Any mixture not adhering shake out. This is a less tiresome process than papering tins which used to be thought necessary. Cakes which need long cooking should be placed on an upturned baking sheet.

**Preparation of Fruit.**—Place fruit on sieve with a tablespoonful of flour, rub well and pick off stalks. Cut raisins open and remove stones. Dip thumb and finger into hot water frequently while doing this. Shred candied peel finely. Peel, shred or chop nuts.

**To Cream Butter and Sugar.**—Beat in a basin with a wooden spoon, add sugar and stir and beat until nearly white and quite creamy. If using more than three eggs the butter is apt to curdle. To check this, add a spoonful of sieved flour with each extra egg and the beating and stirring must be very rapid when adding eggs, as sometimes when slight indication of curdling occurs rapid beating will check it.

Rub the flour and baking powder with salt through a sieve. For very light cakes dry the flour in the oven before sifting. When the cake is cooked turn on to a sieve or wire tray to cool.

**Fundamental Methods.**—There are three fundamental methods of making cakes: (1) Plain cakes, when baking powder is sifted with the flour, fat is rubbed into flour, any dried fruits such as raisins, sultanas, currants, cherries, dates, candied peel, caraway seeds, preserved ginger or nuts are added, according to kind of cake required. Eggs or milk or both are used to moisten. (2) Cakes in which butter or fat and sugar are beaten to a cream, the eggs, if used, added one by one and well beaten in, and the flour, fruit or flavouring stirred in lightly last of all. If a small quantity of fat and one egg only is used in these cakes a little baking powder is required. The quality of the cake is varied by the amount of fat and eggs used in making it. These cakes are sometimes made without fruit, flavoured with essence, or with nuts only. (3) The lightest cakes of all are made by beating up eggs and sugar over hot water to a very stiff froth, then adding sifted flour very lightly. Sometimes a little oiled butter is added to the beaten up eggs, alternately with flour, as in Genoese mixture. These cakes do not contain fruit but are flavoured with various essences. In some cases yolks and whites of eggs are beaten separately and beaten whites stirred in lightly after flour is added.

**Reasons for Failure.**—If cakes containing carbonate of soda or baking powder are not put into the oven quickly after adding moisture they may become heavy. If the oven is not hot enough a cake will not rise well and will be heavy. If the oven is too hot when the cake is put in it will become hollow inside as the mixture will rise too quickly and a hard crust form on the outside before the mixture has had time to rise properly all through. If the fruit sinks in a cake, the mixture has been made too light or the cake has not been put into a sufficiently hot oven. The oven door must not be opened for at least 10 minutes after the cake goes in as sudden draught checks rising. If a cake crumbles when cut it generally means that too much baking powder and too little liquid have been used when mixing, but if a cake is cut too new it will crumble.

**Useful Recipes.**—The following recipes will serve as a basis for a number of different kinds of cakes:

**Plain Fruit Cake.**— $\frac{1}{2}$  lb. flour, 3 oz. butter, lard or margarine, 2 oz. castor sugar, 1 oz. candied peel, pinch of salt, 3 oz. sultanas or currants or both, 1 teaspoonful baking powder, 1 egg,  $\frac{3}{4}$  gill of milk. Mix according to directions (1) and bake in a moderate oven for about 1 hour. This mixture may be used for *rock cakes*. Put it in spoonfuls on a floured tin and bake for about 10 to 15 minutes. It is also suitable for *seed cake*, using a full teaspoonful of caraway seeds instead of the sultanas. It may be made richer by the addition of a second egg.

**Rich Plum Cake.**— $\frac{3}{4}$  lb. flour,  $\frac{1}{2}$  lb. butter,  $\frac{1}{2}$  lb. brown sugar,  $\frac{1}{2}$  lb. mixed peel,  $\frac{1}{2}$  lb. currants, 6 oz. raisins,  $\frac{1}{4}$  lb. sultanas,  $\frac{1}{4}$  lb. almonds, grated rind of half a lemon,  $\frac{1}{2}$  teaspoonful mixed spice, 4 eggs, 1 tablespoonful golden syrup, a very little milk. Make according to directions (2). If liked, half a gill of brandy or cider may be added to this cake mixture; it improves it but is not necessary. For baking, see general rules.

**Sponge Cake.**—5 eggs, their weight in sugar, half their weight in flour, the grated rind and juice of 1 lemon. Make according to directions (3), using yolks and whites of eggs separately and stirring in the stiffly whipped whites at the last. Bake from 40 to 50 minutes in a hot oven, which must be allowed to get cooler.

**Angel Cake.**—Whites of 6 eggs,  $\frac{3}{4}$  breakfastcupful sugar,  $\frac{1}{2}$  breakfastcupful flour,  $\frac{1}{2}$  teaspoonful vanilla,  $\frac{3}{4}$  teaspoonful baking powder, pinch of salt. Sift baking powder five times with flour. Rub sugar through a hair sieve. Whip egg whites very

stiff, adding a pinch of salt, then add sugar to whipped whites, placing it on the end of a plate and gradually beating it in from below. The same should be done with flour, and lastly add flavouring. Keep mixture light, and when once the beating is begun do not stop till finished. Bake from 20 to 30 minutes in a moderate oven. Ice with white glacé icing.

**Glacé Icing.**— $\frac{3}{4}$  lb. icing sugar, juice of half a lemon, a little water. Rub sugar through a hair sieve, put into a clean pan, mix in lemon juice and enough water to make it of the consistency of a stiff sauce. Warm over fire sufficiently to take chill off and when it just coats the back of a wooden spoon pour over the cake.

**Sandwich Cake.**—4 oz. butter, 4 oz. castor sugar, 2 eggs, 6 oz. flour, 1 teaspoonful baking powder, a little milk. Mix according to directions (2): beat until light and creamy, bake in greased sandwich tins or on two enamelled plates for 12 to 15 minutes. Turn out carefully, leave to cool, spread with jam, press together again and ice or leave plain as preferred. This mixture is sometimes known as Genoese.

**Fancy Cakes.**—Use the above mixture but bake in fancy tins or in one large sheet; cut into fancy shapes and decorate as required.

**Layer Cakes.**—Use the same mixture. Spread with fancy filling, press layers together, neaten and ice and decorate as required.

**Chocolate Cake.**—Use the same mixture, adding  $\frac{1}{4}$  lb. chocolate, which has been melted over the fire in 3 tablespoonsful of water, to creamed butter and sugar.

**Gingerbread.**— $\frac{1}{2}$  lb. flour,  $\frac{1}{4}$  lb. butter,  $\frac{1}{4}$  lb. brown sugar, 6 oz. black treacle, 6 oz. golden syrup, 1 teaspoonful ground ginger,  $\frac{1}{2}$  teaspoonful bi-carbonate of soda, 2 fresh eggs, 1 oz. almonds. Put butter, sugar, treacle and golden syrup into a pan over a low fire and stir now and then until sugar and butter are melted. Stir this mixture into the flour, add beaten eggs and mix well. Add enough milk to make the mixture of the consistency of thick custard. Put into a flat tin, bake in a moderate oven from one to one and a half hours. After the cake has risen decorate the top with blanched and split almonds. (D. C. PE.)

**CAKEWALK**, a dance of American negro origin. The couples form a square with the men on the inside and, stepping high to a lively tune, walk in this square formation. There are several judges who consider the precision with which the corners are turned, the elegant bearing and carriage of the men and the grace and ease of their partners as they are swung about. The couples are eliminated one by one, the last being presented with a highly decorated cake, as a reward. This is the original cakewalk, as it was danced in slavery days. From it many modifying steps have been evolved all of which are called cakewalks.

**CALABAR** (formerly Old Calabar), a port of British West Africa, capital of a province of southern Nigeria, on the left bank of the Calabar river in 4° 56' N., 8° 18' E., 5m. above the point where the river falls into the Calabar estuary of the Gulf of Guinea, and 40m. from the sea. (Pop. about 25,000.) From the beach rise cliffs of moderate elevation, and on the sides or summits of the hills are the principal buildings. In a valley between the hills is the native quarter, called Duke Town. Here are several fine houses in bungalow style, the residences of the chiefs or wealthy natives. Among the public institutions are Government botanical gardens, primary schools and the Hope Waddell institute for technical training. Palms, mangoes and other trees give the town a picturesque setting. The trade is largely centred in the export of palm oil and palm kernels and the import of cotton goods. Vessels drawing 20ft. of water can ascend to Calabar. There is no bar in the Calabar river, which is well buoyed, but cargo has to be landed from lighters.

Calabar was the name given by the Portuguese discoverers of the 15th century to the tribes on this part of the Guinea coast at the time of their arrival. It was not till the early part of the 18th century that the Efik, owing to civil war with their kindred and the Ibibio, migrated from the neighbourhood of the Niger to the shores of the river Calabar. The native inhabitants are still mainly Efik. For several generations they were the middlemen between the white traders on the coast and the tribes of the Cross river and

Calabar district. Many of the natives are well educated, profess Christianity and dress in European fashion. A powerful bond of union among the Efik, and one that gives them considerable influence over other tribes, is the secret society known as the Egbo (*q.v.*). The chiefs of Duke Town and other places in the neighbourhood placed themselves in 1884 under British protection.

Until 1904 Calabar was generally, and officially, known as Old Calabar, to distinguish it from New Calabar, the name of a river and port about 100 m. to the east. Since the date mentioned the official style is Calabar simply. Calabar estuary is mainly formed by the Cross river (*q.v.*), but receives also the waters of the Calabar and other streams. The estuary is 10 to 12 m. broad at its mouth and maintains the same breadth for about 30 miles.

**CALABAR BEAN**, the seed of a leguminous plant, *Physostigma venenosum*, a native of tropical Africa. The plant is a climber and attains a height of about 50 ft. with a stem an inch or two in thickness. The seed pods, which contain two or three seeds or beans, are 6 or 7 in. in length; and the beans are about the size of an ordinary horse bean but much thicker, with a deep chocolate-brown colour. Although highly poisonous, the bean has nothing in external aspect, taste or smell to distinguish it from any harmless leguminous seed, and disastrous effects have resulted from its being incautiously left in the way of children.

The bean usually contains a little more than 1% of alkaloids. Of these two have been identified, *calabarine*, and *physostigmine* or *eserine*. Physostigmine is used as the sulphate, which has the empirical formula of  $(C_{15}H_{21}N_3O_2)_2 \cdot H_2SO_4$ , plus an unknown number of molecules of water. It occurs in small yellowish crystals, turned red by exposure to light or air, readily soluble in water or alcohol and with a bitter taste. The dose is  $\frac{1}{10}$  -  $\frac{3}{10}$  grain, and should be administered by hypodermic injection. For the use of the oculist, it is also prepared in *lamellae* for insertion within the conjunctival sac. Each of these contains one-thousandth part of a grain of physostigmine sulphate.

Physostigmine has no action on the unbroken skin. When swallowed it causes great increase in salivary secretion, due to a direct influence on the secreting gland-cells. After a few minutes salivation is arrested owing to constriction of the blood-vessels that supply the glands. Secretion of bile, tears and sweat is also increased. Physostigmine raises the blood pressure, induces constriction of the pharynx and leads to violent vomiting and purging. It also acts upon the bladder, uterus, spleen and iris (*see below*). The terminals of the vagus nerve are also stimulated, causing the heart to beat more slowly. Later in its action, the drug depresses the intra-cardiac motor ganglia, causing prolongation of diastole and finally arrest of the heart in dilatation. The respiration is at first accelerated, but is afterwards slowed and ultimately arrested. The initial hastening is due to stimulation of the vagus terminals in the lung. The final arrest is due to paralysis of the respiratory centre in the medulla oblongata, hastened by a quasi-asthmatic contraction of the non-striated muscular tissue in the bronchial tubes, and by a "water-logging" of the lungs due to an increase in the amount of bronchial secretion. It is only in very large doses that the voluntary muscles are poisoned, there being induced in them a tremor which may simulate ordinary convulsions. The action is a direct one upon the muscular tissue (*cf.* the case of the gland-cells), since it occurs in an animal whose motor nerves have been paralysed by curare.

Consciousness is entirely unaffected by physostigmine, there being apparently no action on any part of the brain above the medulla oblongata. But the influence of the alkaloid upon the spinal cord is great. The reflex functions of the cord are abolished owing to a direct influence upon the cells in the anterior cornua. Near the termination of a fatal case there is a paralysis of the sensory columns of the cord, so that general sensibility is lowered. Calabarine on the other hand, stimulates these functions.

Physostigmine causes a contraction of the pupil more marked than any other known drug. Besides the *sphincter pupillae* the fibres of the ciliary muscle are stimulated. Consequently clear vision of distant objects becomes impossible. The intra-ocular tension is markedly lowered. This action is due to the extreme

pupillary contraction which removes the mass of the iris from pressing upon the spaces of Fontana, through which the intra-ocular fluids normally make a very slow escape from the eye into its efferent lymphatics.

Physostigmine is used chiefly, but not exclusively, by the oculist. He uses it for at least six purposes. Its stimulant action on the iris and ciliary muscle is employed when they are weak or paralysed. It is used in all cases where one needs to reduce the intra-ocular tension, and for this and other reasons in glaucoma. It is naturally the most efficient agent in relieving the discomfort or intolerable pain of photophobia; and it is the best means of breaking down adhesions of the iris, and of preventing prolapse of the iris after injuries to the cornea.

**Toxicology.**—The symptoms of Calabar bean poisoning have been stated above. The obvious antidote is atropine (*q.v.*) which may often succeed; and the other measures are those usually employed to stimulate the circulation and respiration. Unfortunately the antagonism between physostigmine and atropine is not perfect; there comes a time when, if the action of the two drugs be summated, death results sooner than from either alone.

**CALABASH**, the shell of a gourd or pumpkin made into a vessel for holding liquids; also a vessel of similar shape made of other materials. It is the name of a tree, *Crescentia Cujete* (family Bignoniaceae), of tropical America, whose gourd-like fruit is so hard that vessels made of the rind can be used over a fire many times before being burned.

**CALABOZO** or **CALABOSO**, an inland town of Venezuela, once capital of the province of Caracas in the colonial period, and now capital of the State of Guárico. Pop. (1920), 7,123. Calabozo is situated in the midst of an extensive *llano* on the left bank of the Guárico river, 325 ft. above sea-level and 123 m. S.S.W. of Caracas. The plain lies slightly above the level of intersecting rivers and is frequently flooded in the rainy season; in summer the heat is most oppressive, the average temperature being 88° F. The town is regularly laid out with streets crossing at right angles, and possesses several fine old churches, a college and public school. It is also a bishop's see, and a place of considerable commercial importance because of its situation in the midst of a rich cattle-raising country. It is said to have been an Indian town originally,

BY COURTESY OF THOMAS F. LEE

NATIVES CURING AND DRYING THE "RAYA" OR RAY FISH, ON THE GUÁRICO RIVER NEAR CALABOZO

and was made one of the trading stations of the *Compañía Guipuzcoana* in 1730. However, like most Venezuelan towns, Calabozo made little growth during the 19th century. In 1820 the Spanish forces under Morales were defeated here by the revolutionists under Bolívar and Páez.

**CALABRIA**, the name of a territorial district of both ancient and modern Italy, but not signifying the same areas in the two periods.

(1) The ancient district consisted of the peninsula at its S.E. extremity, between the Adriatic and the gulf of Tarentum, ending in the Iapygian promontory (Lat. *Promunturium Salentinum*; the village upon it was called Leuca—Gr. Λευκά, white, from its

colour—and is still named S. Maria di Leuca) and corresponding in the main with the modern province of Lecce, Brundisium and Tarentum being its north-westerly cities, though the boundary of the latter extends somewhat farther west. It is a low terrace of limestone, the highest parts of which seldom reach 1,500 ft.; the cliffs, though not high, are steep, and it has no important rivers, but despite lack of water it was (and is) remarkably fertile. Strabo mentions its pastures and trees, and its olives, vines and fruit trees (still the principal source of prosperity) are frequently spoken of by the ancients. The wool of the good ports of Tarentum and Brundisium was also famous, and at the former place were considerable dye-works. Traces of a prehistoric population of the Stone and early Bronze Age are to be found all over Calabria. Specially noticeable are the menhirs (*pietre fitte*) and the round tower-like *specchie* or *truddhi*, which are found near Lecce, Gallipoli and Muro Leccese (and only here in Italy); they correspond to similar monuments, the *perdas fittas* and the *muraghi*, of Sardinia; and there are also numerous dolmens. In 272–266 B.C. we find six triumphs recorded in the Roman *fasti* over the Tarentini, Sallentini and Messapii, while the name Calabria does not occur; but after the foundation of a colony at Brundisium in 244 B.C., and the final subjection of Tarentum in 209 B.C., Calabria became the general name for the peninsula (for the Iron Age in Messapia see APULIA: *Geometric Pottery*). Strabo tells us that in earlier days Calabria had been extremely populous and had had 13 cities, but that all except Tarentum and Brundisium had dwindled to villages. The Via Appia (*q.v.*), prolonged to Brundisium perhaps as early as 264 B.C., passed through Tarentum; the shorter route by Canusium, Barium and Gnathia was only made into a main artery of communication by Trajan. The only other roads were the two coast roads, the one from Brundisium by Lupiae, the other from Tarentum by Manduria, Nereium, Aletium (with a branch to Callipolis) and Veretum (hence a branch to Leuca), which met at Hydruntum. Augustus joined Calabria to Apulia and the territory of the Hirpini to form the second region of Italy. From the end of the second century we find Calabria for juridical purposes associated either with Apulia or with Lucania and the district of the Bruttii, while Diocletian placed it under one *corrector* with Apulia. The loss of the name Calabria came with the Lombard conquest of this district. For the archaeology of this period see P. Orsi in *Boll. d'Arte* ser. 1, vol. viii. (1914) 41, 337; *Chron. Belle Arti* i. 65; *Le Chiese Basiliane della Calabria* (1927).

(2) The modern Calabria consists of the southern extremity of Italy, bounded on the N. by the province of Potenza (Basilicata) and on the other three sides by the sea. Area 5,819 sq.m. Calabria acquired its present name in the time of the Byzantine supremacy, after the ancient Calabria had fallen into the hands of the Lombards and been lost to the Eastern empire about A.D. 668. The name is first found in the modern sense in the 8th century; the district is mainly mountainous; at the N. extremity the mountains still belong to the Apennines proper (the highest point, the Monte Pollino, 7,325 ft., is on the boundary between Basilicata and Calabria), but after the plain of Sibari, traversed by the Crati (anc. Crathis, a river 58 m. long, the only considerable one in Calabria), the granite mountains of Calabria proper begin. The first group extends as far as the isthmus, about 22 m. wide, formed by the gulfs of S. Eufemia and Squillace; its highest point is the Botte Donato (6,330 ft.). It is in modern times generally called the Sila, in contradistinction to the second (southern) group, the Aspromonte (6,420 ft.); the ancients on the other hand applied the name Sila to the southern group. The rivers in both parts of the chain are short and unimportant. The mountain districts are in parts covered with forest (though less so than in ancient times), still largely government property, while in much of the rest there is good pasture. The scenery is fine, though the country is hardly at all visited by travellers. The fertile coast strip produces wine, olive-oil and fruit (oranges, lemons, figs, etc.), in abundance, especially near Reggio. The neighbourhood of Cosenza is also highly cultivated, though the methods used in many parts are still primitive. Coast fisheries are important near the straits of Messina. The climate is very hot in summer, while

snow lies on the mountain-tops for at least half the year. Earthquakes have done great damage; that of the autumn of 1905 was disastrous, but was surpassed by the terrible earthquake of 1908, which destroyed Messina (*q.v.*) and ruined Reggio. Railway communications include lines along E. and W. coasts (the latter forms part of the through route by land from Italy to Sicily, ferry-boats traversing the strait of Messina with the through trains on board) which meet at Reggio di Calabria. They are connected by a branch from Paola through Corigliano (junction for Cosenza), and Spezzano Albanese (branch to Castrovillari) to Sibari, and by another from Marina di Catanzaro through Catanzaro to S. Eufemia. There are also short branches. The interior is otherwise untouched by railways; indeed many of the villages in the interior can only be approached by paths; and this is one of the causes of the economic difficulties of Calabria. Another is injudicious deforestation. Much is, however, being done in the way of public works; hydroelectric plants have been established in the Sila, and drainage of the plain of Sibari is being undertaken.

Local costumes are still much worn in the remoter districts; they vary considerably in the different villages. The population of Calabria was 1,512,318 in 1921. Colonies, founded in the 15th century by Albanians expelled by the Turks, still speak their own language, wear their national costume and worship according to Greek rite. Similar colonies exist in Sicily, notably at Piana dei Greci near Palermo.

**CALAFAT**, a town of Rumania in the department of Doljiu, on the Danube, opposite the Bulgarian fortress of Vidin. Pop. (1924), 8,000. Calafat is an important centre of the grain trade, and is connected by a branch line with the principal Rumanian railway system and by steam ferry with Vidin. It was founded in the 14th century by Genoese colonists, who employed large numbers of workmen (*Calafats*) in repairing ships—which industry gave its name to the place.

**CALAH**: see KALAKH.

**CALAHORRA** (anc. CALAGURRIS), a city of north Spain, province of Logroño; on the Bilbao-Saragossa railway and a branch line to Arnedo. Pop. (1920) 10,767. Calahorra is built on a hill slope rising from the left bank of the river Cidacos, which enters the Ebro, 3 m. east. It is the market for the grain, wine, oil, vegetables and fruit of the fertile Ebro valley, which it overlooks, and makes jam and artificial manures. The cathedral, dating probably from the foundation of the see of Calahorra in the 5th century, was restored in 1485, and subsequently so much altered that little of the original Gothic structure survives. The Casa Santa, annually visited by many thousands of pilgrims on Aug. 31, is said to contain the bodies of the martyrs Emetarius and Celestinius, who were beheaded in the 3rd or 4th century.

Calagurris became famous in Roman times for its heroic resistance to Pompey in 76 B.C. Hunger had reduced its garrison to cannibalism before they surrendered four years later to Pompey's legate, Afranius. Under Augustus (31 B.C.–A.D. 14) Calagurris received the privileges of Roman citizenship, and later it was given the additional name of *Nassica* to distinguish it from the neighbouring town of *Calagurris Fibularenensis*, the exact site of which is uncertain. The rhetorician, Quintilian, was born at Calagurris Nassica about A.D. 35. The chief Roman remains are the ruins of an aqueduct and an amphitheatre.

**CALAIS**, a seaport and manufacturing town of northern France, in the department of Pas-de-Calais, 18 m. E.S.E. of Dover, and 185 m. N. of Paris by the Northern railway. Pop. (1926) 60,943. The old town stands on an island hemmed in by the canal and the harbour basins which divide it from the much more extensive manufacturing quarter of St. Pierre, enveloping it on the east and south. The demolition of the ramparts of Old Calais was followed by the construction of a new circle of defences now obsolete. Calais was a fishing-village with a natural harbour until the end of the 10th century. It was first improved by Baldwin IV., count of Flanders, in 997, and in 1224 was regularly fortified by Philip Hurepel, count of Boulogne. It was besieged in 1346, after the battle of Crécy, by Edward III. and taken after resisting for nearly a year. The city remained in the

hands of the English till 1558, when it was taken by Francis, duke of Guise, from the ill-provided English garrison. From this time the *Calaisis* or territory of Calais was known as the *Pays Reconquis*. It was held by the Spaniards from 1595 to 1598, but was restored to France by the treaty of Vervins. In the centre of the old town is the Place d'Armes, in which stands the former *hôtel-de-ville* (rebuilt in 1740, restored in 1867). It was much damaged by bombardment (1914-16). The belfry belongs to the 16th and early 17th centuries. Close by is the Tour du Guet, or watch-tower, used as a lighthouse until 1848. The church of Notre-Dame built during the English occupancy shows the influence of English Gothic. A gateway flanked by turrets (14th century) is a relic of the Hôtel de Guise, built as a guild hall for the English woolstaplers, and given to the duke of Guise as a reward for the recapture of Calais. Calais has a board of trade-arbitrators, a tribunal and a chamber of commerce.

Calais is the principal port for the continental passenger and mail traffic with England carried on by the S.R. and the French railways. The principal exports are woven goods, glass-ware, lace and metal-ware. Imports include petroleum, timber, raw wool, cotton yarn. The main industry of Calais is the manufacture of lace, for which it is the chief centre in France. The lace machines are driven by electrical power, a large export being to the United States. Saw-milling, boat-building and the manufacture of artificial ice, biscuits, soap, submarine and telephone cables is also carried on. Deep-sea and coast fishing for cod, herring and mackerel are also important. The tonnage of the port almost doubled between 1913 and 1918, in spite of the stoppage of civilian traffic, owing to the enormous quantity of war material that was dealt with. The port equipment was much improved to cope with military needs; a quay, 280 metres long, was finished in 1918, and the new west dock has a depth of from 26 ft. to 30 ft. on the sill. Work on the entrance to the port was resumed in 1921, and the west jetty completed. By the construction of an elevator, canal boats of 300 tons can reach the large canal dock. The harbour is connected with the river Aa and the navigable waterways of the department.

**CALAIS**, a city of Washington county, Maine, U.S.A., at the head of navigation on the St. Croix river (the international boundary), 12m. from its mouth. It is on Federal highway 1; is served by the Maine Central railroad and is connected by bridges with St. Stephens, New Brunswick, across the river. The population in 1920 was 6,084, 1,426 foreign-born white; 1930, 5,470. The city stretches along the river for 14m., in a wide and picturesque valley. It is a port of entry, a trading centre for a wide area, and a resort for summer tourists and sportsmen. The manufacture of boots and shoes and the canning of blueberries are growing industries, replacing the lumbering and shipbuilding of former days. At Woodland, 11m. W., is a large paper-mill. Near by are quarries of red granite, from which large shipments were made before the growth of the cement industry cut down the market.

In the winter of 1604-5 the Huguenot Pierre du Guast, sieur de Monts, came to the large island in the river on which the United States now maintains a lighthouse, to take possession of his immense grant, but the next summer the survivors of the party returned to France. The first permanent settlement was made by Daniel Hill, a lumberman, in 1779. In 1789 Massachusetts sold the entire site of the present city for \$4,000 to Waterman Thomas, who bought it as a speculation. The first sawmill was built in 1802. The city was chartered in 1851.

**CALAÏS** and **ZETES**, in Greek mythology, the winged twin sons of Boreas and Oreithyeia. On their arrival with the Argonauts (q.v.) at Salmydessus in Thrace, they liberated their sister Cleopatra, who had been thrown into prison with her two sons by her husband Phineus, the king of the country (Sophocles, *Antigone*, 966; Diod. Sic. iv. 44). According to another story, they delivered Phineus from the Harpies (q.v.). They were slain by Heracles near the island of Tenos, in consequence of a quarrel with Tiphys, the pilot of the Argonauts, or because they refused to wait during the search for Hylas (q.v.). Legend attributed the foundation of Calais in Campania to Calaïs (Silius Italicus viii. 512).

**CALAMBA** or **KALAMBA**, a municipality (with administration centre and 36 *barrios* or districts) of the province of Laguna, Luzon, Philippine Islands, about 37 m. from Manila; a port on the south shore of Laguna de Bay, and a junction for railways from Tayabas, Batangas and Pagsanjan. It is a centre of the sugar industry. Pop. (1918) 18,062, of whom 52 were whites. Wooden slippers are manufactured here. In 1918, it had 15 manufacturing establishments with output valued at 101,700 pesos; 4 rice-mills, with output valued at 196,200 pesos; and 46 household industry establishments, with output valued at 24,000 pesos. There were 13 schools, four being public. The Chinese revolt of 1639 began here and here was born the Filipino scholar, patriot and martyr, José Rizal. The language is Tagalog.

**CALAMINE**. The name calamine (Ger. *Galmel*) from *lapis calaminaris* of Pliny, is a corruption of cadmia (καδμία), the old name for zinc ores in general, and was formerly used indiscriminately for the carbonate (see SMITHSONITE) and the hydrous silicate (see HEMIMORPHITE) of zinc; even now both species are included by miners under the same term. The two minerals often closely resemble each other in appearance, and can usually only be distinguished by chemical tests; they were first so distinguished by James Smithson in 1803. F. S. Beudant in 1832 restricted the name calamine to the hydrous silicate and proposed the name smithsonite for the carbonate, and these meanings of the terms are now adopted by Dana and many other mineralogists. Unfortunately, however, in England (following Brooke and Miller, 1852) these designations have been reversed, calamine being used for the carbonate and smithsonite for the silicate.

**CALAMIS**, an Athenian sculptor of the first half of the 5th century B.C. He made statues of Apollo the averter of ill, Hermes the rambearer, Aphrodite and other deities, as well as part of a chariot group for Hiero, king of Syracuse. His works are praised by ancient critics for delicacy and grace. It has been suggested that the bronze charioteer found at Delphi is by Calamis; but the evidence is not conclusive (see GREEK ART).

See H. Stuart Jones, *Ancient Writers on Greek Sculpture* § 78-87 (1895).

**CALAMY, EDMUND**, known as "the elder" (1600-1666), English Presbyterian divine, was born of Huguenot parents in Walbrook, London, in February 1600, and educated at Pembroke hall, Cambridge, where his opposition to the Arminian party, then powerful in that society, excluded him from a fellowship. Nicholas Felton, bishop of Ely, however, made him his chaplain, and gave him the living of St. Mary, Swaffham Prior, which he held till 1626. He then removed to Bury St. Edmunds, where he acted as lecturer for ten years, retiring when his bishop (Wren) insisted on the observance of certain ceremonial articles. In 1636 he was appointed rector (or perhaps only lecturer) of Rochford in Essex, and in 1639 to the perpetual curacy of St. Mary Aldermanbury in London, where he had a large following. He defended the Presbyterian cause, and had a principal share in writing *Smectymnus*, against Bishop Joseph Hall's presentation of episcopacy. The initials of the names of the several contributors formed the name under which it was published, viz., S. Marshal, E. Calamy, T. Young, M. Newcomen and W. Spurstow. Calamy took an active part in the Westminster Assembly, and found in Presbyterianism the middle course which best suited his views of theology and Church government. He opposed the execution of Charles I., lived quietly under the Commonwealth, and was assiduous in promoting the king's return; he declined the bishopric of Coventry and Lichfield, but became one of Charles's chaplains, and vainly tried to secure the legal ratification of Charles's declaration of Oct. 25, 1660. He was ejected for Nonconformity in 1662, and died after the Great Fire on Oct. 29, 1666. His grandson, Edmund (1671-1732), a Nonconformist minister, was a prolific writer, the best known of his works being *An Account of the Ejected Ministers* (1702), and an *Autobiography* (posthumously published, 1829).

**CALARASHI**, the capital of the Jalomitza department of Rumania. Pop. c. 13,000. Situated on the left bank of the Borcea branch of the Danube, the town has considerable transport trade in wheat, linseed, hemp, timber and fish.

**CALAS, JEAN** (1698–1762), a Protestant merchant at Toulouse, whose legal murder is a celebrated case in French history, was born at Lacaparrède, near Chartres, on March 19, 1698. His wife was an Englishwoman of French extraction. They had three sons and three daughters. His son Louis had become a Roman Catholic. In Oct. 1761 another son, Antoine, hanged himself in his father's warehouse. It was alleged that he had been strangled by the family to prevent him from changing his religion, and that this was a common practice among Protestants. The unhappy family were condemned to the rack in order to extort confession. They appealed to the parlement; but this body sentenced the old father to the torture, ordinary and extraordinary, to be broken alive upon the wheel, and then to be burnt to ashes; which decree was executed on March 9, 1762. Pierre Calas, the surviving son, was banished for life; the rest were acquitted. The distracted widow, however, found some friends, and among them Voltaire, who laid her case before the council of State at Versailles. For three years he worked indefatigably to procure justice, and made the Calas case famous throughout Europe (see *VOLTAIRE*). Finally the king and council annulled the proceeding of the parlement of Toulouse; Calas was declared to have been innocent, and a payment was made to the family, but no proceedings were taken against the magistrates or the parlement.

See Voltaire, *Sur la tolérance, à cause de la mort de Jean Calas; Causes célèbres*, tome iv.; Raoul Allier, *Voltaire et Calas, une erreur judiciaire au XVIII<sup>e</sup> siècle* (1898); biographies of Voltaire; and F. H. Maugham, *The Case of Jean Calas* (1928).

**CALASIAO**, a municipality (with administration centre and 16 *barrios* or districts) of the province of Pangasinan, Luzon, Philippine Islands, on a branch of the Agno river, about 4 m. S. by E. of Dagupan; and on the Manila-Dagupan railway. Pop. (1918) 16,960, of whom only one was white. It lies in the midst of a fertile district and has manufactures of hats and various woven fabrics. In 1918 it had 32 manufacturing establishments with output valued at 78,800 pesos, besides 12 sugar-mills and 444 household industry establishments, the latter with output of 127,200 pesos. Of the nine schools six were public. The language spoken is Pangasinan.

**CALASIO, MARIO DI** (1550–1620), Italian Franciscan, was born at Calasio, in the Abruzzi. Joining the Franciscans at an early age, he devoted himself to Oriental languages and became an authority on Hebrew. He was appointed by Paul V., whose confessor he was, to the chair of Scripture at Ara Coeli, where he died on Feb. 1, 1620. Calasio is known by his *Concordantiae sacrorum Bibliorum hebraicorum* (1622), a work which is based on Nathan's *Hebrew Concordance* (Venice, 1523), and evinces great care and accuracy. All root-words are treated alphabetically, and the whole Bible has been collated for every passage containing the word, so as to explain the original idea, which is illustrated from the cognate usages of the Chaldee, Syrian, Rabbinical Hebrew and Arabic. Calasio gives under each Hebrew word the literal Latin translation, and notes any existing differences from the Vulgate and Septuagint readings. An incomplete English translation was published in London by Romaine in 1747. Calasio also wrote a Hebrew grammar, *Canones generales linguae sanctae* (1616), and the *Dictionarium hebraicum* (1617).

**CALATAFIMI**, a town in the province of Trapani, Sicily, 30 m. W.S.W. of Palermo direct (51½ m. by rail). Pop. (1921) 10,259. The name comes from the Saracenic castle of *Kalat-al-Fimi* (castle of Euphemius), which stands above it. Samuel Butler, the author of *Erewhon*, did much of his work here. The battlefield where Garibaldi won his first victory over the Neapolitans on May 15, 1860, lies 2 m. S.W.

**CALATAYUD**, a city of central Spain, province of Saragossa. It lies on the left bank of the river Jalón, just below the entrance of its tributary the Jiloca, and is served by the Madrid-Saragossa and Calatayud-Sagunto railways. Pop. (1920) 12,001. Calatayud consists of a lower more modern and well-built town, and an upper or Moorish town, where there are many rock-hewn dwellings inhabited by the poorer classes. Two collegiate churches are especially noteworthy. Santa Maria, originally a mosque, has a lofty red octagonal tower and a fine Renaissance doorway, added

in 1528; while Santo Sepulcro, built in 1141, and restored in 1613, was long the principal church of the Spanish Knights Templar. Commercially Calatayud ranks second only to Saragossa among the Aragonese towns, for it is the central market of the exceptionally fertile valleys of the Jalón and Jiloca. About 2m. E. are the ruins of the ancient Bilbilis where the poet Martial was born (c. A.D. 40). This town was celebrated for its breed of horses, its armourers, its gold and its iron. Destroyed by the Arabs in the 8th century, its ruins later provided stone for the building of Calatayud, whose name is an adaptation of the Moorish *Kalat Ayub*, "Castle of Ayub."

**CALATIA**, an ancient town of Campania, Italy, 6m. S.E. of Capua, on the Via Appia, near the point where the Via Popillia branches off from it. The history of Calatia is practically that of its more powerful neighbour Capua, but as it lay near the point where the Via Appia turns east and enters the mountains, it had some strategic importance. In 313 B.C. it was taken by the Samnites and recaptured by the dictator Q. Fabius; the Samnites captured it again in 311, but it must have been retaken at an unknown date. In the 3rd century we find it issuing coins with an Oscan legend, but in 211 B.C. it shared the fate of Capua. In 174 we hear of its walls being repaired by the censors. In 59 B.C. a colony was established here by Caesar.

**CALAVERAS SKULL**: see NORTH AMERICA: *Archaeology*.

**CALBAYOG**, a municipality (with administration centre and 31 *barrios* or districts) of the province and island of Samar, Philippine Islands, on the west coast at the mouth of the Calbayog river, about 30 m. north-west of Catbalogan, the provincial capital. Pop. (1918) 25,380, of whom only 28 were whites. Considerable abacá is exported to Manila, and copra is produced in quantity in the region. Some fine timbers are found nearby. Hot springs are located in the neighbourhood. The climate is very warm. A meteorological station has been established here. In 1928 it had 28 manufacturing establishments with output valued at 173,300 pesos and 180 household industry establishments with output valued at 60,400 pesos. Its eight schools are all public. The language spoken is a dialect of Bisayan.

**CALBE** or **KALBE**, a town of Germany, on the Saale in Prussian Saxony, to be distinguished from Calbe on the Milde in the same province. Pop. (1925) 11,476. Its industries are the manufacture of cloth, paper and sugar.

**CALCAR** or **KALCKER, JOHN DE** (1499–c. 1546), Italian painter, was born at Calcar, in the duchy of Cleves, and died at Naples. He was a disciple of Titian at Venice, and perfected himself by studying Raphael. He imitated those masters so closely, especially in his portraits, as to deceive the most skilful critics.

**CALCEOLARIA**, in botany, a genus belonging to the family Scrophulariaceae, containing about 250 species of herbaceous or shrubby plants, chiefly natives of the South American Andes of Peru and Chile, and sometimes called slipperworts. The calceolaria of the present day has been developed into a decorative herbaceous plant. It is generally raised annually from the seed, which is sown about the end of June in a mixture of loam, leaf-mould and sand. In all stages of growth the plants are subject to the attacks of the green-fly. The so-called shrubby calceolarias used for bedding are propagated from cuttings planted in autumn in cold frames.

**CALCHAQUIAN** (Diaguitan), a group of tribes of South American Indians, somewhat doubtfully constituting an independent linguistic stock. The Calchaquis occupied a considerable territory in north-western Argentina, extending from the valley of Lerma near Salta, south and east in the foothills of the Andes and the western edge of the pampas, to the northern border of the province of Cordoba. Some recent authorities would make the stock extend westward to the Pacific coast by uniting the Calchaquis with the Atacamenas (*q.v.*). As practically all data in regard to the Calchaqui language known as "Kakan" has been lost, and the people themselves have for some time been extinct, the problem of determining their limits and affiliations is very difficult. The Calchaquis were a bold and warlike people, and successfully resisted the attacks of the Incas. Culturally their remains show clear relationship with the prehistoric culture of

Bolivia, as well as influences from the historic Inca civilization.

The Calchaquis were sedentary agriculturalists, living in villages of houses built with dry stone walls, sometimes very closely grouped to form communal dwellings somewhat resembling the pueblos of the south-western United States. They had much in the way of copper implements and ornaments, but only a little gold. Textiles were made and pottery of varied types and considerable excellence. The dead were buried and whole cemeteries of urn burials of very young children have been found, supposedly victims of infant sacrifice. In some sections large groups of small mounds associated with stone circles and alignments are found, but their purpose is unknown.

See T. A. Joyce, *South American Archaeology* (London, 1912); A. F. Chamberlain, "The Allentiacan, Bororoan and Calchaquian linguistic stocks of South America," *American Anthropologist* (n.s.), vol. xiv. pp. 499-507. The latter gives a useful bibliography.

(R. B. D.)

**CALCHAS**, son of Thestor, the most famous soothsayer among the Greeks at the time of the Trojan war. He foretold the duration of the siege, demanded the sacrifice of Iphigeneia and the return of Chryseis; he suggested that Neoptolemus and Philoctetes should be fetched to Troy, and advised the construction of the wooden horse. It had been predicted that he should die when he met his superior in divination; and the prophecy was fulfilled in the person of Mopsus, whom Calchas met after the war, at Clarus, or at Siris in Italy. Beaten in a trial of soothsaying, Calchas died of chagrin or committed suicide.

See Roscher's *Lexikon*, s.v.

**CALCINATION**. Solids, when heated to a high temperature for the purpose of removing volatile substances, for the purpose of oxidizing a portion of the mass, or to render them friable, are said to be calcined. Calcination, therefore, is sometimes considered a process of purification. A typical example is the manufacture of lime from limestone. In this process the limestone, usually admixed with coke or other fuel to maintain the high temperature but sometimes treated in rotary kilns heated by gas or powdered fuel, is brought to a temperature high enough to expel the carbon dioxide, producing the lime of commerce in a highly friable or easily powdered condition. Calcination in special cases may be carried on in furnaces designed to exclude air, for which an inert gas may be substituted.

**CALCITE**, a mineral consisting of naturally occurring calcium carbonate ( $\text{CaCO}_3$ ), crystallizing in the rhombohedral system. With the exception of quartz, it is the most widely distributed of minerals, while in the beautiful development and extraordinary variety of form of its crystals it is surpassed by none. In the massive condition it occurs as large rock-masses (marble, limestone, chalk) which are often of organic origin, being formed of the remains of molluscs, corals, crinoids, etc., the hard parts of which consist largely of calcite.

The name calcite (Lat. *calx*, *calcis*, meaning burnt lime) is of comparatively recent origin, and was first applied, in 1836, to the "barleycorn" pseudomorphs of calcium carbonate after celestine from Sangerhausen in Thuringia; it was not until about 1843 that the name was used in its present sense. The mineral had, however, long been known under the names calcareous spar and calc-spar, and the beautifully transparent variety called Iceland-spar had been much studied. The strong double refraction and perfect cleavages of Iceland-spar were described in detail by Erasmus Bartholinus in 1669 in his book *Experimenta Crystalli Islandici diadactylitici*; the study of the same mineral led Christiaan Huygens to discover in 1690 the laws of double refraction, and E. L. Malus in 1808 the polarization of light.

An important property of calcite is the great ease with which it may be cleaved in three directions; the three perfect cleavages are parallel to the faces of the primitive rhombohedron, and the angle between them was determined by W. H. Wollaston in 1812, with the aid of his newly invented reflecting goniometer, to be  $74^\circ 55'$ . The cleavage is of great help in distinguishing calcite from other minerals of similar appearance. The hardness of 3 (it is readily scratched with a knife), the specific gravity of 2.72, and the fact that it effervesces briskly in contact with cold dilute acids are also characters of determinative value.

Crystals of calcite are extremely varied in form, but, as a rule, they may be referred to four distinct habits, namely: rhombohedral, prismatic, scalenohedral and tabular.

Depending on the habits of the crystals, certain trivial names have been used, such, for example, as "dog-tooth-spar" for the crystals of scalenohedral habit, so common in the Derbyshire lead mines and limestone caverns; "nail-head-spar" for crystals terminated by the obtuse rhombohedron *e*, which are common in the lead mines of Alston Moor in Cumberland; "slate-spar" (German *Schieferspat*) for crystals of tabular habit, and sometimes as thin as paper; "cannon-spar" for crystals of prismatic habit terminated by the basal plane.

Calcite is also remarkable for the variety and perfection of its twinned crystals. Twinned crystals, though not of infrequent occurrence, are, however, far less common than simple (un-twinned) crystals.

Calcite, when pure, as in the well-known Iceland-spar, is perfectly transparent and colourless. The lustre is vitreous. Owing to the presence of various impurities, the transparency and colour may vary considerably. Crystals are often nearly white or colourless, usually with a slight yellowish tinge. The yellowish colour is in most cases due to the presence of iron, but in some cases it has been proved to be due to organic matter (such as apocrenic acid) derived from the humus

overlying the rocks in which the crystals were formed. An opaque calcite of a grass-green colour, occurring as large cleavage masses in central India and known as hislopit, owes its colour to enclosed "green-earth" (glauconite and celadonite). A stalagmitic calcite of a beautiful purple colour, from Reichelsdorf in Hesse, is coloured by cobalt.

Optically, calcite is uniaxial with negative birefringence, the index of refraction for the ordinary ray being greater than for the extraordinary ray; for sodium-light the former is 1.6585 and the latter 1.4862. The difference, 0.1723, between these two indices gives a measure of the birefringence or double refraction.

Although the double refraction of some other minerals is greater than that of calcite (e.g., for cinnabar it is 0.347, and for calomel 0.683), yet this phenomenon can be best demonstrated in calcite, since it is a mineral obtainable in large pieces of perfect transparency. Owing to the strong double refraction and the consequent wide separation of the two polarized rays of light traversing the crystal, an object viewed through a cleavage rhombohedron of Iceland-spar is seen double, hence the name doubly-refracting spar. Iceland-spar is extensively used in the construction of Nicol prisms for polariscopes, polarizing microscopes and saccharimeters, and of dichroscopes for testing the pleochroism of gem-stones.

Chemically, calcite has the same composition as the orthorhombic aragonite (*q.v.*), these minerals being dimorphous forms of calcium carbonate. Well-crystallized material, such as Iceland-spar, usually consists of perfectly pure calcium carbonate, but at other times the calcium may be isomorphously replaced by small amounts of magnesium, barium, strontium, manganese, cobalt, zinc or lead.

Mechanically enclosed impurities are also frequently present, and it is to these that the colour is often due. A remarkable case

FIGS. 1-6.—CALCITE CRYSTALS

1. *r* is primitive (cleavage) rhombohedron
2. *e* is flat rhombohedron
3. *f* is acute rhombohedron
4. prism (*m*) combined with rhombohedron (*e*)
5. combination of scalenohedron (*v*) with rhombohedron (*r*)
6. basal pinacoid (*o*) prism (*m*) and rhombohedron (*e*) combined

of enclosed impurities is presented by the so-called Fontainebleau limestone, which consists of crystals of calcite of an acute rhombohedral form enclosing 50 to 60% of quartz-sand. Similar crystals, but with the form of an acute hexagonal pyramid, and enclosing 64% of sand, have been found in large quantity over a wide area in South Dakota, Nebraska and Wyoming.

In addition to the varieties of calcite noted above, some others, depending on the state of aggregation of the material, are distinguished. A finely fibrous form is known as "satin-spar," a name also applied to fibrous gypsum: the most typical example of this is the snow-white material, often with a rosy tinge and a pronounced silky lustre, which occurs in veins in the Carboniferous shales of Alston Moor in Cumberland. Finely scaly varieties with a pearly lustre are known as argentine and aphrite (German *Schaumspat*); soft, earthy and dull white varieties as agarie mineral, rock-milk, rock-meal, etc.—these form a transition to marls, chalk, etc. Of the granular and compact forms numerous varieties are distinguished (see LIMESTONE and MARBLE). In the form of stalactites calcite is of extremely common occurrence.

The modes of occurrence of calcite are very varied. It is a common gangue mineral in metalliferous deposits, and in the form of crystals is often associated with ores of lead, iron, copper and silver. It is a common product of alteration in igneous rocks, and frequently occurs as well-developed crystals in association with zeolites lining the cavities of basaltic and other rocks; and it is said to be a primary constituent in certain igneous rocks. Veins and cavities in limestones are usually lined with crystals of calcite. The wide distribution, under various conditions, of crystallized calcite is readily explained by the solubility of calcium carbonate in water containing carbon dioxide, and the ease with which the material is again deposited in the crystallized state when the carbon dioxide is liberated by evaporation.

Localities at which beautifully crystallized specimens of calcite are found are extremely numerous. For beauty of crystals and variety of forms the haematite mines of the Egremont district in west Cumberland and the Furness district in north Lancashire are unsurpassed. The lead mines of Alston in Cumberland and of Derbyshire, and the silver mines of Andreasberg in the Harz and Guanajuato in Mexico have yielded many fine specimens. From the zinc mines of Joplin in Missouri enormous crystals of golden-yellow and amethystine colours have been obtained.

The quarry, which since the 17th century has supplied the famous Iceland-spar, is in a cavity in basalt, the cavity itself measuring 12 by 5yds. in area and about 10ft. in height. It is

FIGS. 7-10.—FOUR SPECIMENS OF TWINNED CRYSTALS OF CALCITE  
7: Twinned prismatic crystal; 8: twinned scalenohedron; 9: cleavage rhombohedron with twin-lamellae; 10: "heart-shaped" twin

situated quite close to the farm Helgustadir, about an hour's ride from the trading station of Eskifjörður on Reyðarfjörður, on the east coast of Iceland. This cavity when first found was filled with pure crystallized masses and enormous crystals. The crystals measure up to a yard across, and are rhombohedral or scalenohedral in habit; their faces are usually dull and corroded or coated with stilbite. In recent years much of the material taken out has not been of sufficient transparency for optical purposes; this, with limited supply, has caused a rise in price. (L. J. S.)

**CALCIUM** is a metallic element, symbol Ca, and was so named by Sir H. Davy because of its occurrence in chalk (Latin *calx*); atomic number 20, atomic weight 40.07 (two isotopes, 40

and 44, the former greatly predominating, according to F. W. Aston). It has a bright silvery appearance when freshly cut, and tarnishes rapidly and becomes yellowish on exposure to air. It does not occur naturally in the free state but is widely distributed in combination, being the fifth most abundant constituent of the earth's crust. Thus the sulphate constitutes the minerals anhydrite, alabaster, gypsum, and selenite, and the carbonate occurs as the minerals chalk, marble, calcite, and aragonite, and in combination with magnesium carbonate as dolomite. Fluorspar is the fluoride, which also occurs with the phosphate as apatite. The phosphate is the main constituent of bones, and the carbonate of egg-shells.

**Extraction.**—Lime was from remote ages regarded as an elementary earth, but in 1808 Sir H. Davy showed that it was an oxide of a metal which he named calcium and endeavoured to isolate. Having just obtained sodium and potassium by electrolytic methods, he tried to decompose a mixture of lime and mercuric oxide by the electric current, but he was unable to get rid of all the mercury from the resulting amalgam. Bunsen, however, met with more success in electrolyzing calcium chloride moistened with hydrochloric acid, and A. Matthiessen obtained the metal by electrolysis of a mixture of fused calcium and sodium chlorides. H. Moissan obtained metal of 99% purity by electrolyzing calcium iodide at a low red heat, using a nickel cathode and a graphite anode, and also by heating the iodide with excess of sodium, forming an amalgam of the product, and removing the sodium by means of absolute alcohol (which does not affect calcium, see later) and the mercury by distillation.

The development of electrolytic methods resulted in the commercial production of the metal. O. Ruff and W. Plato employed a mixture of the chloride and fluoride (fluorspar), which was fused in a porcelain crucible and electrolysed by a carbon anode and an iron cathode; this method did not admit of commercial application, but W. Rathenau and C. Suter achieved this object by a slight modification. A graphite vessel, which contained the fused mixture, served as the anode, and the cathode was an iron rod which could be gradually raised, and which is known as the "contact cathode." This just touches the surface of the fused mixture, and as the calcium forms at the point of contact the rod is raised, whereby the calcium is produced as a rod forming a prolongation of the iron rod. It is marketed in this form and has a purity of 98-99%. More recent methods (e.g., that of Brace, *J. Inst. Metals*, 1921, xxv., p. 161) tend to revert to the electrolysis of concentrated calcium chloride solutions with a mercury cathode, and subsequent distillation of the mercury.

**Properties.**—A. W. Hull has shown that the crystal structure of the metal is a face-centred cube, the edge being 5.56 Å.U. in length. Calcium reacts slowly with the oxygen and nitrogen of the air to form a yellow surface layer of hydroxide and nitride. It is rapidly acted upon by water, but the resulting layer of hydroxide tends to protect the metal from further attack owing to its sparing solubility. Alcohol is practically without action, and for this reason calcium is used as the best means of removing the last traces of water from alcohol. The chemical properties of calcium, strontium, and barium are very similar, showing a regular gradation throughout the series; these elements together with magnesium constitute the so-called "alkaline earths." Calcium combines directly with most elements, including nitrogen with which it forms the nitride,  $\text{Ca}_3\text{N}_2$ . Its combination with oxygen is so intense that if effected at 300°C. the heat evolved suffices to volatilise the lime produced. Its specific gravity is about 1.54, depending upon its previous treatment. It melts at 810°C., but sublimes at a lower temperature; its specific heat is 0.169 at 20°C.; it is malleable and can be drawn into wire.

**Compounds.**—Calcium hydride,  $\text{CaH}_2$ , obtained by heating the metal in a current of hydrogen, is known as hydrolith, and was used by the French for filling dirigibles, since it is portable and on treatment with water yields one cubic metre of hydrogen per kilo. It is stable at 600°C. in a vacuum. On electrolysis in a fused (eutectic) mixture of potassium and lithium chlorides, it gives hydrogen quantitatively at the anode, a matter of great theoretical interest (D. C. Bardwell). Calcium forms the monoxide,  $\text{CaO}$ , the

peroxide,  $\text{CaO}_2$ , and possibly a tetroxide,  $\text{CaO}_4$ . The monoxide and the corresponding hydroxide are lime and slaked lime. The peroxide is obtained by the addition of hydrogen peroxide to lime water, the resulting hydrate,  $\text{CaO}_2 \cdot 8\text{H}_2\text{O}$ , losing water on being heated to  $130^\circ$  and giving the peroxide as a pale buff-coloured powder. It is used to a slight extent for bleaching and antiseptic purposes. The  $\text{CaO}_4$  is obtained by warming the foregoing hydrate on the water-bath with concentrated hydrogen peroxide; it has a strong yellow colour.

Whereas calcium chloride, bromide, and iodide are very deliquescent soluble substances, the fluoride is insoluble in water; this constitutes a striking contrast with the silver salts for the fluoride is the only soluble one in this case. Calcium fluoride,  $\text{CaF}_2$ , occurs as fluorspar or may be prepared as an insoluble white precipitate by mixing solutions of calcium chloride and sodium fluoride; it requires about 60,000 parts of water for solution at  $18^\circ$ . The chloride,  $\text{CaCl}_2$ , occurs in many natural waters and as a by-product in many manufacturing processes. According to conditions the crystals may contain 2, 4, or 6 molecules of water; the anhydrous chloride is obtained by heating the crystals in a current of hydrogen chloride above  $200^\circ$ , and is used as a desiccating agent (but not for ammonia or alcohols, with which it forms compounds). It melts at about  $775^\circ$ . The hexahydrate dissolves in water with absorption of heat, and if mixed with three-quarters of its weight of snow, it produces a temperature of  $-55^\circ\text{C}$ . At  $175^\circ$ , 100 parts of water will dissolve 297 parts of  $\text{CaCl}_2$ , and the solution boils a few degrees higher. Concentrated solutions find a limited use for laying dust. The bromide and iodide closely resemble the chloride.

"Bleaching powder" is said to be a compound of the chloride and hypochlorite,  $\text{CaCl}_2$ ,  $\text{Ca}(\text{OCl})_2$ , but it has been shown (E. A. O'Connor, 1927) that such a compound does not exist, so that its constitution is still indefinite. It is made by exposing thin layers of slaked lime to chlorine at  $30$ – $40^\circ\text{C}$ . (see ALKALI MANUFACTURE and BLEACHING).

Calcium carbide,  $\text{CaC}_2$ , manufactured by heating lime and carbon in the electric furnace, is of great importance since it gives rise to acetylene (*q.v.*) on reacting with water. It reacts with the nitrogen of air in the electric furnace to give calcium cyanamide (see CYANAMIDE).

Calcium carbonate,  $\text{CaCO}_3$ , occurs in minerals (above) and in natural waters, in which it is kept in solution by atmospheric carbon dioxide as the bicarbonate,  $\text{Ca}(\text{HCO}_3)_2$ . The loss of this carbon dioxide by evaporation or heating of the solution results in the deposition of  $\text{CaCO}_3$ , and hence the "hardness" of the water due to this cause is called "temporary." The chalk thus deposited is called "fur" in boilers or kettles, but if it is produced by the dripping of water in caves it forms stalactites and stalagmites. It also occurs in the skeletons of sponges and corals. The solubility in water containing the amount of carbon dioxide normally derived from the atmosphere is 1 part in 16,000 parts, but under higher pressures of the gas it is much more soluble, and under a pressure of 15 atmospheres it seems to be entirely converted into the bicarbonate. "Precipitated chalk" is prepared by mixing solutions of calcium chloride and a soluble carbonate (usually that of sodium).

Calcium nitride,  $\text{Ca}_3\text{N}_2$ , is formed by heating calcium (preferably slightly impure, for the pure metal is almost inert) in nitrogen; it is a greyish-yellow powder, and is readily decomposed by water, with formation of ammonia.

Calcium nitrate,  $\text{Ca}(\text{NO}_3)_2$ , is a highly deliquescent salt; from its occurrence in limestone caverns and its disintegrating action on mortar, it is variously called "lime-salt-petre" and "salt-petre-rot." The anhydrous nitrate is phosphorescent and is known as "Baldwin's phosphorus." The hydrate,  $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ , is obtained in the "flaming arc" process for "fixing" atmospheric nitrogen, and is used as an artificial manure either directly or after conversion into ammonium nitrate.

Calcium phosphide,  $\text{Ca}_3\text{P}_2$ , is obtained as a reddish substance by passing phosphorus vapour over strongly heated lime. It is used as a marine signal fire ("Holmes lights") owing to its property of giving a spontaneously inflammable hydrogen phosphide

on reacting with water. It may also be prepared by direct combination of calcium metal with phosphorus vapour.

Normal calcium phosphate,  $\text{Ca}_3(\text{PO}_4)_2$ , is the principal inorganic constituent of bones and hence of "bone-ash" (see PHOSPHORUS); it occurs as the concretion known as coprolites, and also in vast masses in Florida and in certain Pacific Islands. It may be obtained artificially as a gelatinous precipitate by mixing solutions of calcium chloride, sodium phosphate, and ammonia. It is insoluble in water, but soluble in solutions of hydrochloric or nitric acids. Basic (or Thomas) slag, a by-product of the steel industry, owes its use as a fertilizer to the calcium phosphate which it contains. The acid salt,  $\text{CaH}_2(\text{PO}_4)_2$ , obtained by evaporating a solution of the normal salt in hydrochloric or nitric acid, is very soluble, and together with calcium sulphate constitutes the artificial manure "superphosphate of lime," which is obtained by treating ground bones or coprolites with sulphuric acid. Other phosphates occur in guano and elsewhere. It is used in medicine; as a source of phosphorus; polishing powder; ceramics; porcelain manufacture; enameling; manufacturing milk glass.

Calcium sulphide,  $\text{CaS}$ , is formed by heating the sulphate with charcoal, or by heating lime in a current of sulphuretted hydrogen; after being heated or exposed to the sun, it shows a phosphorescence, apparently in virtue of minute traces of impurities, especially compounds of the heavy metals, which it contains; hence it is known as "Canton's phosphorus" (John Canton, 1718–1772). The hydrosulphide,  $\text{Ca}(\text{SH})_2 \cdot 6\text{H}_2\text{O}$ , is obtained by saturating a cold suspension of lime with sulphuretted hydrogen; it is used as a depilatory. The di- and penta-sulphides,  $\text{CaS}_2$  and  $\text{CaS}_5$ , are formed when milk of lime is boiled with flowers of sulphur; they form the basis of Balmain's luminous paint. They are also contained in "liver of sulphur," a complex mixture prepared by heating together lime and flowers of sulphur. It is also used in medicine.

Calcium sulphide,  $\text{CaSO}_3 \cdot 2\text{H}_2\text{O}$ , is prepared by passing sulphur dioxide into milk of lime; excess of the former leads to a solution of "bisulphite of lime," used for bleaching wood pulp in the manufacture of paper.

Calcium sulphate,  $\text{CaSO}_4$ , occurs as certain minerals and in water, in which it is one of the salts causing "permanent hardness," *i.e.*, it is not removed on boiling. As a white crystalline precipitate it is obtained on mixing solutions of calcium chloride and sodium sulphate; 100 parts of water dissolve 0.24 parts at  $15^\circ\text{C}$ . The ordinary dihydrate is converted into a semihydrate,  $\text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$ , on being heated to a suitable temperature ( $120$ – $180^\circ$ ); this hydrate is called Plaster of Paris, having first been made from the gypsum of Montmartre.

There are numerous calcium silicates in various minerals, of which the most important are zeolites and feldspars. H. Le Chatelier obtained  $\text{CaSiO}_3$ ,  $\text{Ca}_2\text{SiO}_4$ ,  $\text{Ca}_3\text{Si}_2\text{O}_7$ , and  $\text{Ca}_5\text{Si}_3\text{O}_{14}$  artificially.

**Detection and Estimation.**—Most calcium compounds impart an orange-red colour to the flame of the Bunsen burner, more especially if they are moistened by hydrochloric acid. Spectroscopically, calcium exhibits two characteristic lines— $\text{Ca}_\alpha$ , orange,  $\lambda 6163$ , and  $\text{Ca}_\beta$ , green,  $\lambda 4229$ . Calcium is not precipitated by sulphuretted hydrogen either in acid or in ammoniacal solution, but is precipitated by ammonium carbonate in the presence of ammonia. Sulphuric acid precipitates the white sulphate except from very dilute solutions; and ammonium oxalate gives the oxalate as a white precipitate, insoluble in dilute acetic acid. Calcium is usually separated in this form and subsequently dried and either converted to the oxide by heat or to the sulphate by sulphuric acid, and weighed as such.

Calcium salts are not toxic, except possibly in very large doses; deficiency of calcium in the diet leads to "rickets," owing to the lack of material for bone formation. (A. D. M.)

**CALCULATING MACHINES.** The evolution of numbering and of numerical calculation is embodied in that simple but great mechanical calculating instrument known as the abacus. (See ABACUS.) The efficiency of this instrument in expert hands has been recognized from early times, and it is still largely employed in India, China, Russia and Japan.

In 1617, John Napier of Merchiston published a description of

his numbering rods, since known as "Napier's bones," for facilitating the multiplication of numbers. These were widely used during the 17th century, and various modifications have been made since they were introduced. The set shown in Pl. I., fig. 1, which belonged to Charles Babbage, is preserved in the Science Museum at South Kensington, where there are other sets, some of which have come from the Napier family. The strips bear the columns of numbers of the ordinary multiplication table. To multiply 765479 by any number, the strips are selected from the case and arranged as shown. The "sevens" strip bears the numbers 7, 14, 21, 28, etc., but written in the form  $\begin{smallmatrix} 7 \\ 14 \\ 21 \\ 28 \end{smallmatrix}$  etc. Horizontally opposite 6 on the index to the left, the product  $6 \times 765479$  is indicated. The rule is: For units, put down the lower right-hand figure, for "tens," etc., add diagonally in pairs and we get 4592874. If the multiplier consists of several figures, the product of each with the multiplicand is read off separately, written down as in ordinary multiplication and added up. Sir Samuel Morland in 1666 invented a multiplying instrument, in which Napier's rods are replaced by rotatable disks, and the figures, instead of being in the two diagonal halves of squares, are arranged near the edge of the disk at opposite ends of diameters. For any given multiplicand, set by placing the appropriate disks on spindles, the partial products were at once indicated by means of a slot-marker, actuating the disks through a rack and pinions. Gaspard Schott in 1668 described the cylindrical form of Napier's bones, which facilitated manipulation. A similar instrument, stated to have been the property of John Napier, is preserved in the Science Museum. In 1885 M. Genaille made the further improvement of eliminating the slight but repeated mental effort required to add the pairs of adjacent figures before writing down the separate products. These ingenious devices, though in some cases embodying rudimentary mechanical arrangements, are not usually described as machines.

**The First Real Calculating Machine.**—This, as the term is usually understood, was invented by Blaise Pascal in 1642. Pascal made a considerable number of machines, a few of which are preserved in the Conservatoire des Arts et Métiers at Paris. Figure wheels, each bearing the numbers 0 to 9, are mounted in a box and have parallel axes with a stylus or peg, a (Pl. I., fig. 2) horizontal wheel at the front and immediately under the cover of the machine can be advanced one-tenth to nine-tenths of a complete turn, the same movement being transmitted by pin wheel gearing to the corresponding figure-wheel. The uppermost figure of each figure-wheel is seen through a sight-hole in the cover. During the movement of the figure-wheel from 9 to 0, a "carrying" device moves the next figure-wheel to the left through one-tenth of a revolution. In machines made by Pascal for adding livres, sous and deniers, the wheels for sous and deniers were modified for recording 0 to 19 and 0 to 11 respectively. In 1666 Morland invented a compact little instrument for the same purpose, measuring 3 in. by 4 in. by less than  $\frac{1}{2}$  in. thick. It was operated by a stylus, but there was no tens-carrying device; the numbers to be carried were registered on small counter-disks. Viscount Charles Mahon (afterwards the 3rd Earl Stanhope) in 1780 improved Morland's instrument by providing a tens-carrying device. This acted simultaneously from the units wheel to those of higher denominations, and the addition of 1 to 999,999, for instance, was almost beyond the capacity of the instrument owing to the great force required. Dr. Roth in 1842 improved this type of stylus-driven instrument, by arranging for the successive carrying of tens. Low-priced instruments of this general type are still being made in considerable numbers.

**Multiplication Machines.**—Multiplication is really repeated addition. For example,  $7543 \times 634 = (7543 + 7543 + 7543 + 7543) + (75430 + 75430 + 75430) + (754300 + 754300 + 754300 + 754300 + 754300 + 754300)$ . Multiplication can therefore be performed in a simple manner by all adding machines of the Pascal type, but the time occupied would be about the same as by the ordinary figuring method on paper. In the above example, for instance, there would be 52 separate operations by hand, each operation involving the placing of the stylus in its proper hole and by its means driving the figure-wheel through its proper arc.

After Pascal's invention the next great advance was due to

Gottfried Wilhelm Leibniz, who in 1671 conceived the idea of a calculating machine which would perform multiplication by rapidly repeated addition. It was not until 1694 that his first complete machine was actually constructed. The figure-wheels on the fixed portion of the machine register the results of additions, rapidly repeated up to nine times of the multiplicand, which was set on a sliding portion, movable by steps into positions corresponding to units, tens, hundreds, etc. This machine is still preserved in the Royal Library at Hanover, and examination has shown that the tens-transmission mechanism was never quite reliable in operation. A second machine was made in 1704, but this has disappeared.

An important unit of the machine was a stepped wheel—a cylindrical wheel or drum having on a portion of its outer surface nine teeth of increasing length, from one to nine. This element is embodied in many subsequent machines which perform multiplication by repeated addition, and is in considerable use at the present time.

During the 18th century many attempts were made by different mathematicians and mechanists to evolve a satisfactory machine which could be made commercially. Among these machines may be mentioned those of Lepine (1725), Leupold (1727), Boistes-sandeau (1730), Gersten (1735), Pereire (1750), Hahn (1774), Mahon (Earl Stanhope) (1775 and 1777), and Müller. The chief difficulty, however, was the high degree of accuracy necessary in the construction of the details such as wheel teeth.

**The First Successful Calculating Machine Manufactured on a Commercial Scale.**—This was that invented in 1820 by Charles Xavier Thomas, of Colmar in Alsace. This model forms a distinct type which has persisted up to the present day, with modifications and improvements in detail due to various makers. By 1865, 500 machines had been made, and 1,000 more were made during the next 13 years. The machine is still made in Paris by Darras, the present successor of the original makers. The example shown in Pl. I., figs. 3, 4, was made about 1866.

The mechanism may be divided into three distinct portions concerned with setting, counting and recording respectively. These are arranged in order from front to back. Any number up to 999,999 may be set by moving the pointers in one or more of the six slots in the fixed coverplate, to the numbers 0 to 9 engraved on the cover plate to the left of each slot. The movement of any of these pointers slides a small pinion with ten teeth along a square axle, underneath and to the left of which is a Leibniz stepped wheel. This is driven from the main shaft by means of a bevel wheel, and the small pinion is thus rotated by as many teeth as the cylinder bears in the transverse plane corresponding to the digit set. This amount of rotation is transferred through one of a pair of bevel wheels carried on a sleeve on the same axis, to the "results" figure-wheel on the back row on the hinged plate. This plate also carries the figure-wheel recording the number of turns of the driving crank for each position of the hinged plate. According to whether the lever at the top left-hand corner of the fixed plate is set for "Addition and Multiplication" or "Subtraction and Division," one or other of the pair of bevel wheels is placed in gear with a bevel wheel underneath a "results" figure-wheel, which is thereby rotated anticlockwise in the direction 0 to 9, or clockwise respectively. The actual operation in multiplying 3,042 by 536, for example, may be performed as follows:—First lift the hinged plate, turn and release the two milled knobs so as to bring all the figure-wheels to show zero. Lower the hinged plate in its position to the extreme left. Set the number 3,042 on the four slots on the fixed plate. Set the lever on the left to "multiplication" and turn the handle, which can be turned only in a clockwise direction, six times. Lift the hinged plate, slide it one step to the right and lower it into position. Turn the handle three times. Step the plate again one point to the right and turn the handle five times. The product 1,630,512 will then appear on the top row, and the multiplier 536 on the next row of figures.

In 1878, the modern German calculating machine industry was founded by Arthur Burkhardt, who commenced the manufacture of this type of machine, under the title of "Burkhardt Arithmometer." Amongst the machines of this form constructed by

other firms are:—Saxonia (1895), Peerless (1904, the late key-board models being known under the name Badenia), Gauss (1905; a small circular type, embodying a circular stepped plate in place of the Leibniz wheel), Archimedes (1906), Tim (1907, made with two slides under the name Unitas), Hermes (1911), Record (1913), Rheinmetall (1924)—in Germany; Layton (1883, known also as the "Tate"), Edmondson (1885, a circular type)—in England; Graber (1905), Austria (c. 1906, known in Germany as the Austro-Germania), Bunzel-Delton (1908)—in Austria; Fournier-Mang (1919)—in France; Kuhrt (1923) in Switzerland; Allen (1927) in the United States of America.

**Machines of the Odhner Type.**—In 1875 Frank Stephen Baldwin patented a machine in which the Leibniz stepped wheel was replaced by a wheel from the periphery of which a variable number of teeth (1 to 9) could be protruded. About the same time W. T. Odhner designed a machine embodying the same device. This type of machine has been made and developed extensively in Germany by Grimme Natalis and Company, since 1892, under the name "Brunsviga." By 1912, 20,000 machines of this type had been constructed by this firm alone. An early example made in 1892, is shown in Pl. I., figs. 5, 6.

Though the machine performs multiplication by repeated addition, as in the Thomas type, the use of the thin Odhner wheel instead of the Leibniz wheel, led to a more compact design. The Odhner wheels (nine in the example shown) fit very close together on the axle at the back. A setting lever, the end of which projects through a slot in the cylindrical portion of the cover plate, forms part of each wheel. If a lever is set against any figure (1 to 9) of its slot, a corresponding number of teeth are made to project from its wheel. When the operating handle is turned, these teeth gear with small toothed wheels of the product register, which in turn gear with the number wheels in front. The product register is mounted on a longitudinally movable carriage arranged in front of the machine, which carries also a second counter for registering the multiplier in the case of multiplication and the quotient in division. For addition and multiplication, the handle is turned in a clockwise direction; for subtraction and division, in the reverse direction, no change of gear being necessary as in machines of the Thomas type. The carriage is stepped to the right or left by pressing one or other of the projecting pieces in front. Zeroization of the product and multiplier registers is effected by turning the butterfly nuts on the ends of the carriage through a complete revolution.

Under the original Odhner patents and since these have run out, this type of machine has been made under various names by many firms in different countries. Amongst these machines are the Brunsviga (1892, known in France as the "Rapide"), Monopol-Duplex (1894), Berolina (1901), Triumphator (1904), Thales (1911), Teetzmann (1912, known in England as "Colt's Calculator"), Lipsia (1914), Rema (1915), Hannovera (1921), Orga (1921), Monos (1923), Gauss (1923), Mira (1924), Hamann-Manus (1925) in Germany; Dactyle (c. 1905), Sanders (1912), Muldivo (1924) in France; Marchant (1911), Lehigh (1919), Arrow (1921), Rapid (1923) in the United States; Original-Odhner (a model adapted for British currency is sold in England under the name "Lusid"), Facit (1918), Odhner Universal (1925), Mercur (1925), in Sweden; Demos (1923, recently sold in England under the name "Eos"), in Switzerland; Calco (1921) in Denmark; and the Britannic (1922) in England.

The machine, which is made in various sizes and capacities, has been steadily modified and improved in details of construction up to the present time. In the latest model by the original German makers, which was issued at the beginning of 1927 under the name Nova Brunsviga (Pl. I., fig. 7), there is a change of design. Amongst other new features is a device by which the result registered on the product dials can be instantly transferred to the setting levers. In a model previously introduced—the "Triplex"—giving 20-figure results, the result register can be divided into two parts, enabling multiplication of two different numbers by the same multiplier to be carried out in one operation.

**Key-driven Machines.**—The keyboard type of calculating machine, which originated and has been developed chiefly in the

United States, may be divided into two distinct classes, key-driven and key-setting. In the former the energy necessary to drive the machine is provided by simply depressing the keys, without any auxiliary movements. The first key-driven adding machine which was patented in U.S.A. by D. D. Parmalee, in 1850, could add only a single column of digits at a time. Many others of this limited capacity were invented before 1887. In this year Dorr Eugene Felt patented his Comptometer, which was the first successful key-driven multiple-order calculating machine. In the first models, each key had to be operated separately so as to ensure the proper carrying of the tens. In subsequent models many improvements were made which contributed to speed, ease and accuracy of operation. In the "Duplex" model introduced in 1903, simultaneous depression of keys in every column, without interfering with the proper carrying of tens, became possible for the first time. This constituted a great advance, and an extremely high speed in operation was thereby attainable. Later, in order automatically to prevent the operator from overlooking any errors which might arise from imperfect operation, the "controlled-key" model was introduced. Interference guards at the side of the key-tops prevented accidental depression of a key near the one being operated. If a key is not given its full downward stroke, the keys in all the other columns are immediately locked, and the numeral wheel in the column where the error is made shows a figure in the answer register standing out of alignment. The error can then be corrected by completing the unfinished stroke. By another automatic block device, no key can be depressed again until it has completed its up stroke. In the most recent models (Pl. I., fig. 8), a short-pull zeroizing lever replaces the longer double-stroke lever, and at the beginning of a new calculation a clear register is indicated to the operator by visible, audible and sense-of-touch signals.

**Adding and Listing Machines.**—In 1872 E. D. Barbour incorporated a printing device with an adding machine. Other inventions of this type were made by F. S. Baldwin (1875), H. Pottin (1883) and A. C. Ludlum (1888). The first really practical adding and listing machines were produced by D. E. Felt in 1889, and by W. S. Burroughs in 1892. Both these inventors had realized the wide field of work, in banking and accounting work generally, to which an efficient machine of this type could be applied, and it is largely due to their steady efforts towards modifying, perfecting and advocating the adoption of such machines that the initial opposition to their use was gradually overcome. Up to the present time well over a hundred different models of the Burroughs machines have been designed and more than a million machines have been made.

A section of one of these machines is shown in Pl. I., fig. 9. The essential element is a lever pivoted near the middle, and carrying at one end a set of type figures T for printing, and at the other end a segmental rack, with which an adding wheel is alternately in and out of gear. The depression of a numeral key brings the end of a stop wire into a position which limits the possible downward travel of the rack. When the operating handle is actuated, this downward travel, during which the adding wheel is out of gear, raises the other end of the lever so as to bring the proper type figure into position for printing. After the printing is effected, the wheel comes into gear with the rack which during its ascent turns the adding wheel through a number of teeth equal to the number of the depressed key.

These machines may be grouped as follows: (a) Single counter adding machines, in which subtraction is performed by the complementary method. (b) Single counter adding machines, with direct subtraction. Where direct subtraction is provided for, the item is set up on the keyboard as if for addition, but the depression of a "subtraction" control key causes the item to be subtracted. The provision of this latter feature enlarges the scope of performance so as to include accounting work, where balances are obtained by the addition and subtraction of various amounts. (c) Duplex and multiple counter adding machines, without direct subtraction. The provision of two or more separate counting mechanisms enables operations to be carried out together, which on single counter machines have to be performed separately. (d) Duplex and multiple counter adding machines, with direct subtraction. (e) Billing,

## EXAMPLES OF CALCULATING MACHINES AND SLIDE RULES

1. Millionaire calculating machine, 1914. Slide-board arrangement of setting mechanism replaced by keyboard in later models
2. Madas calculating machine, 1920, similar to Thomas machine (Plate I). Sliding controls operate the mechanism. In addition to usual operations, this machine automatically performs division
3. Mercedes-Euklid machine, 1914, a modification of the Thomas machine. Recent models have keyboard instead of sliding control and perform multiplication and division automatically
4. Monroe calculating machine, 1925. The slide contains wheels for adding and multiplying, performed by turning crank at side in opposite directions
5. Ensign calculating machine, 1927, with auxiliary keyboard. This machine performs multiplication by repeated addition
6. United listing multiplying machine, 1927, performs automatic multiplication and lists or prints the totals on strip of paper
7. Slide rules: (a) Mannheim type; (b) Dunlop & Jackson's log-log slide rule; (c) Percy's log-log slide rule

accounting and book-keeping machines. These are designed to deal with such work as the preparation of invoices, reports, business forms and allied documents, where typewriting is combined with arithmetical computations and recording. The first practical machine of this type was the Moon-Hopkins billing machine, invented by Hubert Hopkins. This machine, which embodies a direct multiplication mechanism of the Bollée and Millionaire type, is the only example in this series equipped for direct multiplication.

In accordance with this broad classification, the groups into which the many machines made in the United States at the present time would fall are indicated in the following list (the larger firms make both hand and electrically operated machines, in various capacities): Add-Index (*a*), Allen-Wales (*a, b, c*), Barrett (*a*), Burroughs (*a, b, c, d, e*), Corona (*a*), Dalton (*a, b, c, d, e*), Elliott-Fisher (*e*), Ellis (*a, c, d, e*), Federal (*a, b*), Gardner (*a, b, c, d*), Hayes (*a*), National (*e*), Peters (*a*), Remington (*e*), Sundstrand (*a, b, c, e*), Underwood (*e*), Victor (*a*).

In 1916 the design and construction of the American type of machine was also taken up in Germany, where it is being considerably developed. Amongst these machines, made in various styles and capacities, are the Continental (1916), Adma (1919), Goerz (1921), Astra (1922), Naumann (1922), Votam (1922), Tim-Add (1923). Typewriters with adding mechanism are represented by the Urania-Vega (1920) and the Mercedes-Elektra (1924). There are also several adding mechanisms made for use in combination with a standard typewriter.

**Cash Registers.**—Of all the different types of machines embodying adding mechanisms, the cash register, used in most retail stores, is the most familiar to the general public. Up to the present time some three million examples of the "National" cash register have been made since 1883 by the pioneer firm of Patterson Brothers in Dayton, Ohio. Standard cash registers of the same general design and principle of action are made by the American, Federal, Remington and other firms.

Though its original object was the prevention of dishonesty in retail stores, the machine has been developed so as to provide also, in many of its forms, an automatic record of cash transactions, together with the issue of duplicate receipts to customers. In the most highly developed model of the "National," 29 individual totals, corresponding with the sales of each clerk or each class of object, may be accumulated, as well as three grand totals. The machine has also been adapted for the purposes of accounting and book-keeping.

Since 1919 a combination type of cash register has been developed, in which a cash drawer is combined with an adding and listing machine. This possesses the advantage that the latter can be used independently when required for general purposes. When used in combination, provision is made for the automatic opening of the drawer as each item is dealt with.

**Direct Multiplication Machines.**—Attempts to transform Napier's rods into mechanically operative form were made in the United States by Edmund D. Barbour (1872) and Ramon Veree (1878), who patented their devices, which, however, never went beyond the first model stage. The first machine to perform multiplication successfully by a direct method, and not by repeated addition, was invented by Léon Bollée in 1887. The essential feature of the mechanism is the multiplying piece, which consists of a series of tongued plates, representing in relief the ordinary multiplication table up to "nine times." Though excellent in action, few of these machines were made, chiefly because the inventor soon became fully occupied with his work in connection with automobilism.

The "Millionaire" machine (Pl. I., fig. 1), patented by Otto Steiger in 1893, was first made and marketed by Egli in 1899. It embodies the mechanical multiplication table invented by Bollée, by the operation of which only one turn of the driving handle is required for each figure of the multiplier. The carriage, or "recorder," being moved to the extreme right, the multiplication lever is set successively to one of its positions 0 to 9 in accordance with the figures of the multiplier, starting with the figure of the highest order. At each setting of the multiplication lever, the

driving crank is turned once; and during the second quarter of each turn the carriage is automatically "stepped" to the left.

The mechanism includes nine parallel toothed racks, the ends of which are in line successively with either the tens or the units group of the tongues of a tongue plate. During each rotation of the crank the tongue plates are twice thrust against the ends of the racks; during the first thrust the tens tongues operate, and the units tongues during the second thrust. In the machines as now made the slot-markers have been replaced by a keyboard.

**Mercedes-Euklid Calculating Machine.**—This machine (Pl. II., fig. 3) was designed by Ch. Hamann and marketed in 1910. Externally, in the general disposition of its main parts, it resembles the Thomas machine, but internally there are many innovations. The Leibniz wheel is replaced by a series of ten parallel racks, actuated from the driving handle by means of a connecting rod and proportion lever. The carriage with its mechanism slides on rollers along guides in the frame of the machine, and can be "stepped" longitudinally without the lifting which is necessary in machines of the Thomas type. The pushing of the carriage to the right stretches a spiral spring, the contraction of which supplies the force for "stepping," which is controlled by the depression of a key. The left-hand member of the pair of levers at the top left-hand corner is placed at the bottom of its slot and the right-hand member at the top. The handle is now turned until it locks, which is the signal for reversal of the levers; the handle is turned again until it locks, when the levers are again reversed. This cycle of operations is repeated until the carriage has returned to its normal position, when the quotient is given in the front row and the remainder in the middle row of figures. Multiplication is performed as with the Thomas machine, starting with the carriage to the extreme right.

In more recent examples the slot markers are replaced by a keyboard, and both multiplication and division can be performed automatically.

**Madas Calculating Machine.**—This machine (Pl. II., fig. 2), first introduced by Hans W. Egli in 1908, resembles the Thomas type. The operations of addition, multiplication and subtraction are performed in the usual way, but there is additional mechanism which enables division to be performed quite automatically, after setting the dividend and divisor. The ringing of a bell announces that the quotient and remainder are recorded (Pl. II., fig. 4).

**Monroe Calculating Machine.**—This was introduced in 1911 by Jay R. Monroe and Frank S. Baldwin. It embodies a keyboard setting mechanism, combined with a slide at the back for "stepping," in the operations of multiplication and division.

The slide contains wheels, which are actuated by a crank handle turned in a clockwise direction for addition or multiplication, and in the reverse direction for subtraction and division, as in machines of the Odhner type. The wheels for adding are made in two co-axial parts, one with five equal teeth and the other with four, arranged in steps. The setting of a particular figure adjusts the two parts towards each other so as to enable 1, 2, . . . 9 teeth to gear with the counting wheel when the handle is turned. Division is by repeated subtraction in the ordinary way, but is rendered semi-automatic by the ringing of a bell when each "won't-go" stage is reached; the handle is then turned once forward, and the slide is moved one step.

In the "full automatic" motor-driven model introduced recently, division is quite automatic, and multiplication is automatic to the extent that only successive depression of keys on the secondary keyboard is required, corresponding with each digit of the multiplier.

**Tabulating and Sorting Machines.**—In connection with the U.S. Census Bureau, an automatic system (known as the Hollerith system) was invented for dealing analytically and statistically with the enormous mass of information obtained. This system, which was also applied to the results of the British census of 1911, has been modified and developed to meet the needs of large commercial firms. By this system, many operations which, if performed by the ordinary mental and manual methods, would be economically impracticable, are carried out quickly and accurately by automatic machines.

The basis of the system is a Jacquard card, in which each fact or item is indicated by a hole punched in a certain position. These cards, which are printed with vertical columns of figures from 0 to 9 or 0 to 12, are prepared by means of a special punching machine; as many holes may be punched as are required to register every detail of each item. The cards are of two forms, dual and single; the former bearing written information corresponding with the punched-hole record, the latter bearing only punched-hole records corresponding with information recorded separately in some other form.

In the Hollerith sorting and tabulating machines the principle of electrical contacts is adopted, circuits being closed when steel brushes pass the holes in the cards. The controls are set by means of wires plugged into a switchboard in such a manner as to connect each punched position on the cards with a column in the counting register, or a sector of the printing mechanism. Changes in the circuit arrangements may be made by the operator in accordance with the particular sorting or tabulating which is being dealt with.

The vertical sorting machine will sort at the rate of about 250 cards a minute; in a later horizontal model the rate is as high as 350 to 400 a minute. The sorting and tabulating machines are electrically driven and the latter are of two main types, in one of which the results are indicated by counters, while the other gives also a printed record.

Jacquard cards are used in a similar manner in the Powers tabulating and sorting machines, which, however, function mechanically by means of pins passing through the holes in the cards.

**Progress** towards the completely automatic calculating machine for rapidly performing with equal facility all the ordinary operations of addition, subtraction, multiplication and division once the numbers have been set, is at an interesting stage. The application of the electric motor drive to many machines, replacing the turning of a handle, has been an important development during the last 20 years. From the advantage which it gives of greater rapidity in setting the figures to be operated on, the keyboard is gradually replacing the slideboard in machines of the Thomas, Odhner and other types designed primarily for multiplication and division—speeding up also the operations of addition and subtraction on such machines. In the Comptometer, and in the other key-driven non-printing adding machines of the same type introduced in more recent years (Burroughs Calculator, Mechanical Accountant) addition is extremely rapid and quite automatic. Multiplication and division are also performed with great rapidity, but in the absence of a slide, greater mental strain is involved and greater dexterity in operation is required. In key-set motor-driven adding and listing machines of the Burroughs and allied types, automatic control is made as complete as possible by the provision of various auxiliary keys (add, non-add, subtract, repeat, sub-total, total, non-print, etc.).

Automatic multiplication was almost completely attained in the Bollée and Millionaire machines, but the figures of the multiplier have to be applied successively. The same has resulted in recent years, so far as automatic control is concerned, in certain machines (Fournier-Mang, Monroe, Marchant, Ensign (Pl. II., fig. 5), Peerless, Record, Kuhrt) which perform multiplication by repeated addition. By depressing one of an additional row of keys (usually termed a secondary or auxiliary keyboard) to the left or right of the main keyboard, the number set on the main keyboard is rapidly added one to nine times according to the number on the key depressed.

In 1910-1912 Alexander Reznitzer of Vienna patented a machine in which after the two numbers to be multiplied or divided had been set up, operation was performed automatically. In 1920 Torres exhibited and designed an electrical arrangement which provided complete automatic control of the operations of multiplication or division performed by a machine of the Thomas type, after the numbers had been set up on a typewriter. Neither of these machines has taken commercial form. The only machine on the market which performs both multiplication and division entirely automatically, once the figures are set, is the Mercedes-Euklid.

A motor-driven multiplying machine (Pl. II., fig. 6), "United

accounting machine," made in St. Louis, Michigan, U.S.A., is being marketed which claims to perform multiplication automatically. The keyboard is in two equal portions, the multiplicand being set on the left and the multiplier on the right. On depressing the motor-bar, the result is both obtained and printed in three seconds. The carrying of tens in this machine is not by one unit at a time, but any number of units up to nine may be carried simultaneously from one column to the other.

In the "Barbel" system, developed by M. Barr and R. A. Bell, the rapid counting of small steel balls introduced a new feature into the design of electrically-controlled calculating machines. Though machines with this particular feature have not yet reached the commercial stage, it would be unwise to assume that development in the future will be confined to improvement and elaboration of existing types of machine. Invention and construction in the calculating machine industry are very much alive at the present time, especially in the United States and in Germany.

**Difference and Analytical Engines.**—In 1812, Charles Babbage (1792-1871) conceived the idea of a calculating machine of a different type from those previously described. The object of the machine was to calculate and print mathematical tables such as tables of logarithms. The machine worked on the method of differences and was known as a "difference engine." The principle underlying the method may be understood by taking a table such as the table of cubes of successive numbers 1, 2, 3, etc., and subtracting each tabular number from the following one, obtaining another column of figures, called the first order of differences. Treating the numbers in this column in the same way, a column of second differences is obtained; on differencing a third time (in this particular case) a constant difference (6) is obtained. By reversal of the process, knowing the constant third difference and the numbers shown at the top of the columns, it is possible to obtain all the rest of the numbers by simple addition. It is the function of a difference engine to effect these additions successively in the proper order so as to obtain the desired series of tabular numbers automatically, once the initial numbers are set.

Babbage's difference engine was commenced in 1823 by authority and at the cost of the Government. The work was suspended in 1833, and in 1842 the Government decided to abandon the machine on the ground of the estimated expense of its completion. The whole engine was intended to have 20 places of figures and six orders of differences. In 1833 a large part of the engine had been made and a small portion had been assembled in order to show the action of the mechanism.

From 1833 Babbage devoted his energies and resources to the design and construction of an "analytical engine," the object of which was to evaluate automatically any mathematical formula. Features of the difference engine were to be embodied in this new engine and the various operations were to be controlled by punched cards of the Jacquard type. The scheme proved to be too ambitious, and the machine was left unfinished when Babbage died. Portions of the machine, with all his notes, drawings and notations are preserved in the Science Museum.

From 1834 to 1853 George Scheutz of Stockholm and his son Edward designed another difference engine, the first complete example being constructed by C. W. Bergström. It was exhibited in operation in Paris and London, and finally purchased for the Dudley Observatory, Albany, U.S.A. A second example was made by Bryan Donkin in 1858 for the General Register Office, Somerset House, and used during the next few years for computations in connection with the preparation of the English life tables. Dr. Farr, the author of this book, states: "This volume is the result; and thus—if I may use the expression—the soul of the machine is exhibited in a series of tables which are submitted to the criticism of the consummate judges of this kind of work in England and in the world." Other engines of this type were designed and made by Martin Wiberg in Sweden, and G. B. Grant in the United States; others were designed by Léon Bollée in France, and Percy E. Ludgate in Ireland, but were not constructed.

**Slide Rules.**—In all the machines previously described the arithmetical results obtained are correct to the last figure indicated

on the dials. There are many calculations in engineering, physics, etc., where an approximate result, rapidly obtained, is frequently desirable, and the logarithmic slide rule provides for this requirement in a very efficient manner.

The invention of logarithms in 1614 by John Napier of Merchiston, and the computation and publication of tables of logarithms, made it possible to effect multiplication and division by the more simple operations of addition and subtraction. (See LOGARITHMS.) In 1620 Edmund Gunter plotted logarithms on a two-foot straight line. With such scales, multiplication and division were performed by addition and subtraction of lengths by a pair of dividers.

William Oughtred, according to his own statement (1633) constructed and used as early as 1621, two of these Gunter's lines sliding by each other so as to do away with the need for dividers. The lines were used in both the straight and circular forms. In the former the scales were held against one another by the hands; in the latter, dividers were replaced by an "opening index"—really a pair of dividers fixed centrally on the circular scale. Richard Delamain in 1630 gave the first published description of a circular slide rule, both in the flat and cylindrical forms. Thomas Brown introduced the spiral logarithmic line in 1633.

The first known slide rule in which the slide worked between parts of a fixed stock was made by Robert Bissaker in 1654. Others were due to the enterprise of Seth Partridge (1657), Henry Coggeshall (1677)—a slide in a 2 ft. folding rule adapted to timber measure, and Thomas Everard (1683) for gauging purposes. The one for gauging purposes, approximated in dimensions and arrangement of scales, to the present-day roin. slide rule, and many thousands were made and sold during the period 1683 to 1705. The usefulness of the slide rule for rapid calculation became increasingly recognized, especially in England, during the 18th century, and the instrument was made in considerable numbers, with slight modifications.

Improvements in the direction of increased accuracy in graduation, etc., were initiated by Boulton and Watt from about 1779 in connection with calculations in the design of steam engines at their works at Soho, Birmingham. The rule evolved, which was the first designed for engineers, became known as the "Soho" rule. It was made by W. and S. Jones, Rooker, Bate and Nairne and Blunt.

The runner or cursor, though its advantages had been pointed out by Robertson (1778) and Nicholson (1787), was not added by instrument makers until Tavernier-Gravet introduced the Mannheim type of slide rule in 1850. This slide rule was much used in France and since about 1880 was imported in large numbers into other countries. Up to this period the rule had been constructed usually of boxwood and occasionally of brass or ivory, but a great improvement was introduced in 1886 by Dennert and Pape in Germany by dividing the scales on white celluloid, which gave a much greater distinctness in reading. This material is now almost universally adopted, and the slide rule made by such firms as Nestler, Faber (Germany), Keuffel and Esser (U.S.A.), Tavernier-Gravet (France) and Davis (England) attain a high degree of perfection.

The disposition of the scales in the Mannheim rule (Pl. II., fig. 7a) is the arrangement still adopted in the great majority of rules made at the present time. The A and B scales are double lines as in the Everard, Coggeshall and Soho rules, but the C and D scales are single lines like the D scale of the Soho rule. At the back of the slider are scales giving the sine and tangent scales and a scale of equal parts. Applied in conjunction with the scales on the face of the stock these are used for reading the values of sines, tangents and logarithms respectively, and in computations involving these factors.

To secure an additional significant figure, the length of the logarithmic scale has to be increased ten times. To keep the dimensions of a slide rule bearing such a scale within reasonable limits four different types of design have been evolved:—(a) The flat spiral form. Examples have been made at various times since the invention of the slide rule, but this type has never been much used. (b) The cylindrical helix. Fuller's slide rule, originally de-

signed in 1878, has been in considerable use up to the present time. Amongst other rules of this type are the Otis King calculator (1922) and the R.H.S. calculator. (c) The flat gridiron type, in which the scale is cut up into strips mounted parallel to each other; examples designed by Everett (1866), Scherer (1892), Hannyington, Rieger (1920), Gladstone and others have been in considerable use. (d) The cylindrical gridiron type. The parallel strips are arranged longitudinally on the surface of a cylinder; examples made and in use at the present time are those of E. Thacher (1881) and the Rouleau calculator.

In 1815 Dr. Peter M. Roget invented his "log-log" slide rule for performing the involution and evolution of numbers. The fixed scale, instead of being divided logarithmically, is divided into lengths which are proportional to the *logarithm of the logarithm* of the numbers indicated on the scale; the sliding scale is divided logarithmically. By employing this new method of graduation, the value of any expression of the form  $y^x$  may be obtained by the same mechanical process as that by which  $yx$  is obtained in the ordinary slide rule. Since  $\log(y^x) = x \log y$ ,  $\log(\log y^x) = \log x + \log(\log y)$ . Hence if division 1 on the slider be set opposite y on the fixed scale, the value of  $y^x$  will be read off on the fixed scale opposite x on the slider. All problems such as those of compound interest, increase of population, etc., are solved in this manner by mere inspection. The lower log-log scale on the stock is numbered 1.0024 to 1.25, and the upper log-log scale is numbered 1.25 to 10<sup>10</sup>. The log-log scale was reinvented and applied to the slide rule by Captain J. H. Thomson in 1881, and by Prof. John Perry in 1902. In Perry's log-log slide rule (Pl. II., fig. 7c) there are two log-log lines, one above and the other below the four scales of the ordinary roin. slide rule. The upper scale reads (left to right) from 1.1 to 10,000, and the lower one the reverse way from 0.0001 to 0.91. The scales, which are reciprocal with each other, are used in conjunction with the B scale on the slider. Lieut.-Col. H. G. Dunlop and C. S. Jackson arranged the log-log lines on a spare slider (Pl. II., fig. 7b) used with the D scale of an ordinary slide rule.

**BIBLIOGRAPHY.**—H. P. Babbage, *Babbage's Calculating Engines* (1889), brings together information from various sources, relating to the calculating machines of Charles Babbage; R. Mehmke, "Numerisches Rechnen," in *Encyklopädie der Mathematischen Wissenschaften*, vol. i, part 2; pp. 952-978; 1.053-1.065 (1900-04); M. d'Ocagne, *Le Calcul Simplifié*, 2nd ed. (1905); F. Cajori, *A History of the Logarithmic Slide Rule*, with full bibliography from 1620-1909 (1909); L. Jacob, *Le Calcul Mécanique* (1911); E. M. Horsburgh, *Handbook of the Exhibition at the Napier Tercentenary Celebration* (1914); *Bulletin de la Société d'Encouragement pour l'Industrie Nationale* (Sept.-Oct. 1920), vol. cxx. No. 5, commemorating the centenary of the invention of the Thomas de Colmar calculating machine, and including papers by M. d'Ocagne, Paul Toulon, M. L. Torres y Quevedo; bibliographies by L. Malassis, E. Lemaire and R. Grelet; reprints of important papers in previous numbers (1822-95) relating to the machines of Thomas de Colmar, Bollée, etc.; illustrated catalogue of the early and modern machines in the exhibition held in Paris (June 1920) in connection with the centenary. J. A. V. Turck, *Origin of Modern Calculating Machines* (Chicago, 1921), deals more particularly with the evolution and development of keyboard adding machines of the Comptometer and Burroughs types; E. M. Horsburgh, "Calculating Machines," *Glazebrook's Dictionary of Applied Physics* (1923); E. Martin, *Die Rechenmaschinen und ihre Entwicklungsgeschichte* (Pappenheim, 1925) (all types of calculating machines, described in order of date of introduction); D. Baxandall, *Mathematics I., Calculating Machines and Instruments* (H. M. Stationery Office, 1926); a catalogue of the calculating machines and instruments exhibited in the Science Museum, South Kensington, with descriptive and historical notes and illustrations; L. J. Comrie, "On the Application of the Brunsviga-Dupla Calculating Machine to double Summation with finite Differences," *Monthly Notices of the Royal Astronom. Soc.*, vol. lxxviii. (1928), pp. 447-459. (D. B.)

**CALCULI or STONES** may occur in any hollow organ in which there is stagnation of the fluid contents together with an excess of some particular substance in solution: they may also occur in the ducts leading from glands from the same cause (see Plate). The chief places where stones occur are in the urinary system and in the gall-bladder.

**Urinary Calculi.**—Calculi may be found in almost any part of the urinary system from the collecting tubules in the kidney where they are microscopic in size, to the bladder where they are known as sand, gravel or stones, according to size. In the

kidney calculi are usually composed of a mixture of uric acid and water, and occasionally of calcium oxalate. There is evidence that minute concretions of these substances may form in the collecting tubules of the kidney, and pass down to the renal pelvis where they become the nucleus for the further deposit of material to form larger stones. Numerous small stones may be found in the renal pelvis, or a single large branching calculus may be formed, filling up the entire pelvis of the kidney. A small calculus may pass down the ureter into the bladder and there increase to a considerable size; in passing down the ureter, it gives rise to renal colic (*see COLIC*). If the calculus becomes impacted, usually at the upper end of the ureter, the condition known as hydronephrosis occurs and this is likely to be followed by an infective inflammation going on to suppuration and ulceration.

Calculi in the bladder may have their origin in the kidney, as already stated, or in the bladder itself; in the latter case they may occasionally form around foreign bodies introduced into the bladder, but in the majority of cases this is not so and the exact method of formation *de novo* is not yet fully understood, but may be due to the deposition of crystals on organic debris, or on a small focus of organisms. The exact nature of the crystalline material forming the stone depends almost entirely upon the chemical constituents of the urine in which they are formed. In many cases a stone is formed over a period of years, and as the urine may alter its character frequently in this time, a stone is often composed of layers very different in colour, chemical composition and hardness. Calculi may grow to a great size without causing any symptoms, if smooth, but as they are usually angular or rough on the surface, bleeding generally occurs.

Sometimes a calculus composed almost entirely of one substance is found, the substances which give rise to such a stone being uric acid, calcium oxalate, xanthin, cystin or calcium phosphate. More commonly one of these substances forms the nucleus of a larger stone, the outer layers of which may be formed of several different substances such as carbonates and phosphates. The nature of calculi varies according to their composition; uric acid calculi are hard, smooth and oval or rounded when found in the bladder, or moulded to the cavity when found in the renal pelvis. Pure calcium oxalate stones are rare, but mixed stones in which this substance forms a considerable part are common. Such stones are often formed around a nucleus of uric acid or urates and are distinguished by their dark brown colour and very rough, jagged exterior. Further deposition of other substances may convert the jagged stone into a smooth one. Phosphatic calculi are formed when the bladder is inflamed and are usually rough and often crumble easily. Cystine calculi are very rare; when they occur they are rather soft and may reach the size of a hen's egg. Xanthin calculi also are extremely rare, only a few isolated specimens having been described in medical literature.

The effect of a large calculus is obstruction: so long as the stone remains loose the obstruction will be intermittent and may largely depend upon the posture of the patient. If the stone becomes impacted or large, obstruction will become complete.

**Biliary Calculi or Gall-stones** are formed from the constituents of the bile together with a certain amount of organic material, and their formation largely depends upon stagnation of bile in the gall-bladder. Their composition and shape vary in the same manner as urinary calculi, the chief constituents being cholesterol, bile pigments and lime salts. There is usually a nucleus which is commonly almost pure cholesterol. Occasionally a stone is composed of almost pure cholesterol and is quite clear and pale yellow in colour: these stones are usually oval and solitary, lying loose in the neck of the gall-bladder. More often they are covered by a coloured secondary deposit. The commonest type by far is the mixed calcium-bilirubin-cholesterol stone; these may occur as single large stones or multiple smaller ones numbering many hundreds in a single case. The large single ones are oval, and the smaller multiple ones faceted. The colour varies from pure white through yellow and green to black. All gall-stones contain a considerable quantity of organic matter and may contain living bacteria.

Gall-stones, either single or multiple, may cause no symptoms

and are often not discovered during life; on the other hand they may give rise to serious effects, partly mechanical and partly inflammatory in character. The inflammatory effects cause inflammation of the gall-bladder or cholecystitis. A large stone may become impacted in the neck or the duct of the gall-bladder and cause great distension, a smaller gall-stone may pass out of the gall-bladder and become impacted lower down the common bile duct giving rise to biliary colic and jaundice. In more chronic cases with a subsequent acute inflammation, a gall-stone may ulcerate through either into the peritoneal cavity or into some portion of the gut. In the former case, peritonitis will set in, and in the latter the stone may be small enough to pass right through the bowel or may become impacted and give rise to acute intestinal obstruction. This may also be the result when the stone passes down the duct from the gall-bladder into the gut. Subsequent to passage of a gall-stone through the common bile duct or coincident with the presence of a gall-stone in the gall-bladder, localized carcinoma may develop.

**Pancreatic Calculi** are rare. They form in the pancreatic duct and are composed mainly of calcium carbonate and phosphate: they are usually small in size and may be numerous. In shape they are rounded or oval, and in colour whitish. If they become impacted in the duct obstruction will follow and bacteria may gain a foothold and set up an acute inflammation. When some pancreatic juice can escape the duct becomes distended.

**Salivary Calculi** may occur in the ducts of the salivary glands, probably from the depositions of salts on inspissated mucus. They are uncommon, but when they occur they are rough, irregular and white; they consist chiefly of calcium phosphate and carbonate. They may occlude the duct partially or completely, causing inflammation and dilatation of the duct and atrophy of the gland. Dentists refer to tartar on teeth as salivary calculus.

**Intestinal Calculi** always have a nucleus of some indigestible material; in countries where oatmeal is largely eaten they are not infrequent. They may cause little or no symptoms, but if large may cause intestinal obstruction. In animals such as the horse and cow they are of relatively common occurrence and may attain to many pounds in weight; they occur chiefly in the stomach and have a nucleus of hair. Another type of concretion found in the intestine is called *Intestinal Sand* and is probably formed in the upper part of the large intestine.

**Preputial Calculi** are sometimes formed by the deposition of urinary salts upon the accumulated smegma under a prepuce that cannot be retracted.

**Prostatic Calculi** occur chiefly in the lateral lobes by the deposition of salts on the normal corpora amylacea. They may reach a considerable size and obstruct the outflow of urine.

**Nasal Calculi or Rhinoliths** occur around nasal secretions or blood clots, but most frequently around foreign bodies introduced into the nasal cavities; they contain a considerable amount of organic matter.

**Mammary Calculi** are sometimes formed in the lactiferous ducts of the breast causing a similar condition in the gland to salivary calculi.

**Lung Calculi** are occasionally found in the bronchi. They may be formed in the same manner as calculi in other sites, or as the result of a piece of calcified lung tissue becoming separated through suppuration. If the obstruction be complete collapse of that portion of the lung behind the obstruction follows, if incomplete the result is bronchiectasis.

**Uterine Calculi or Womb Stones** sometimes occur, usually, as the result of calcareous degeneration of a tumour; occasionally a foetus may die in utero and later become encapsuled and calcified, forming a large calcified mass in the cavity of the uterus known as a lithopaedion.

A considerable amount of work of different kinds has been done on calculi, especially the commoner ones. Their chemical composition is known moderately accurately; gall-stones, as has been stated, may be formed round a nucleus of organisms, and if these belong to the typhoid group, the stones may be a source of danger by starting an epidemic of typhoid fever at a later date. Certain gall-stones from cases of cancer of the gall-bladder have been

## FORMS OF CALCULI

1. Gallstone, pure cholesterin, cut section. 2. Gallstone, pure cholesterin. 3. Gallstone, mixed composition, faceted. 4. Gallstones composed almost entirely of bile pigments. 5. Gallstone of mixed composition, largely cholesterin. 6. Salivary calculus, mainly calcium phosphate and carbonate. 7. Renal calculus, smooth, chiefly salts of uric acid. 8. Renal calculus, "mulberry," chiefly oxalate of lime. 9. Renal calculus composed of cystin. 10. Renal calculus, smooth, chiefly salts of uric acid. 11. Bladder calculus,

uric acid nucleus, superficial laminae of calcium and ammonio-magnesium phosphates (section). 12. Bladder calculus, phosphatic, nucleus of hazelwood (section). 13. Bladder calculus, phosphatic around oxalate calculus, (section). 14. Intestinal calculus, ammonio-magnesium phosphate with plumstone as nucleus (section). 15. Intestinal calculus from horse (reduced), ammonio-magnesium phosphate with pebble as nucleus (section). 16. Intestinal calculus composed of ammonio-magnesium phosphate

found to contain minute traces of radioactive substances. In some cases both gall-stones and urinary calculi will act upon a photographic plate in the dark; this action is believed to be due to the action of hydrogen peroxide produced from turpines, or to minute traces of ammonia. The effect can be produced either at room temperature or at 37°C; at the latter temperature a few hours may suffice. (P. L.-B.)

### CALCULUS, DIFFERENTIAL AND INTEGRAL.

The differential calculus and the integral calculus are the two divisions of a branch of mathematics which treats problems involving variable quantities. Such problems arise regularly in geometry, physics and other branches of science. By a *quantity*, is meant a distance, a weight, a period of time, in short, anything which can be measured.

The two leading problems of the *differential calculus* are the construction of tangents to curves and the determination of the rate of change of a quantity. A tangent to a curve is a straight line which grazes the curve at a point. Thus  $AB$ , in fig. 1, is tangent to the curve in the figure. A more careful analysis of the notion of tangent will be given below. In elementary geometry, the construction of a tangent to a circle is considered. The differential calculus furnishes a method for constructing tangents to curves of any type.

FIG. 1.—TANGENCY

A typical situation connected with a rate of change is as follows: suppose that water is flowing into a vessel in the shape of an inverted cone (fig. 4), at the uniform rate of 1 cu. ft./sec. At first the water will rise rapidly in the cone, and then, because the upper part of the cone is wider than the lower part, the level will go up more and more slowly. The differential calculus permits the determination of the rate at which the level rises at any stated instant. One of the most interesting special problems in the differential calculus is the determination of the maximum or minimum value a quantity can have. The differential calculus also furnishes methods for calculating tables of logarithms, sines, cosines, etc., which are used in trigonometry and in developing two important formulae, Taylor's formula and Maclaurin's.

The *integral calculus* treats of two classes of problems. The first class deals with such quantities as the amount of area enclosed by a curve, the length of a curve, or the amount of volume enclosed by a surface. The second type of problem is the determination of a variable quantity when the law of its change is known. For instance, let a body be dropped from a height, in a vacuum. We know that the speed with which it is falling, at any instant, is proportional to the length of time for which it has been falling. The speed is nothing more than the rate of change of the distance which the body has fallen. The integral calculus permits the determination of the distance through which the body falls in any period of time.

**Function.**—The theory of the calculus rests upon three fundamental ideas—the ideas of *function*, *derivative*, and *integral*. In the development of the notion of derivative, the important concept of *limit* will enter. The notion of function can be brought out readily by means of an example. If the length of the side of a square is known, the area of the square can be calculated immediately. This fact is expressed in the language of mathematics by saying that the area of a square is a function of the length of its side. More generally, if when the value of one quantity is known the value of a second quantity can be found, the second quantity is called a *function* of the first.

If the quantity which is given is called  $x$ , and the quantity which is found is called  $y$ , the fact that  $y$  is a function of  $x$  is expressed by the symbolism  $y=f(x)$ , that is, "y equals f of x". In each particular problem,  $f(x)$  becomes a definite mathematical expression. For instance, if  $x$  is the length of the side of a square,

and  $y$  is the area of the square, then  $y$  equals  $x^2$ , so that  $f(x)$  in this case is  $x^2$ . Other letters than  $f$  may be used as functional symbols. For instance, where several functions appear in the same problem, one might call them  $f(x)$ ,  $F(x)$ ,  $g(x)$ , etc., respectively.

It is not essential that a change in  $x$  should cause  $y$  to change. All that is important is that  $y$  should be capable of determination when  $x$  is known. A function which has the same value for every value of  $x$  is called a *constant*. Thus, if  $y=2$  for every value of  $x$ , then  $y$  is a constant. While constant functions play a fundamental rôle in the calculus, it is difficult to find concrete examples of such functions which do not appear trivial. The density of an incompressible fluid at any point, regarded as a function of the depth of the point, is a constant. The ratio of the area of a circle to the square of the radius of the circle is, regarded as a function of the radius, a constant; its single value is  $\pi$ .

**Tangents.**—The concept of derivative is perhaps best brought out by considering the construction of a tangent to a curve. Assuming some familiarity on the part of the reader with the graphing of curves, we will show the construction of a tangent to the curve whose equation is  $y=x^2$  at the point  $(2, 4)$ . The curve is a parabola (fig. 2).

FIG. 2.—TANGENTS

Let  $Q$  be any point on the parabola, distinct from the point  $P(2, 4)$ . Let  $P$  be joined to  $Q$  by a straight line. We shall call the line  $PQ$  a *secant*. Now, let the point  $Q$  come closer and closer to  $P$ , without attaining to  $P$ . As  $Q$  approaches  $P$ , the secant will rotate about  $P$ , and will tend towards coincidence with a line through  $P$  which touches the parabola at  $P$  without cutting across the parabola. This line will be called the *tangent* to the parabola at  $P$ .

The tangent at  $P$  can certainly be constructed if the angle which it makes with the  $X$ -axis is known. We shall call the angle between a line and the  $X$ -axis the *inclination* of the line. In what follows immediately, the inclination of the tangent will be found from the fact that, as the secant approaches the tangent, the inclination of the secant approaches that of the tangent. One point deserves special emphasis. We have not said that if  $Q$  comes into coincidence with  $P$ , the secant becomes a tangent. Unless  $Q$  is distinct from  $P$ , we do not have two points through which to draw a line. All that has been said is that, as  $Q$  comes closer and closer to  $P$ , the inclination of the secant comes closer and closer to that of the tangent. This fact suffices for the determination of the slope of the tangent.

**Limit.**—To express the fact that the inclination of the secant approaches that of the tangent, we shall say that the inclination of the tangent is the *limit* of the inclination of the secant. In general, when a variable quantity comes closer and closer to a fixed quantity, we shall say that the variable quantity has the fixed quantity as a limit. It is not essential that the variable quantity should move steadily in the direction of the fixed quantity. For instance, as the vibrations of a pendulum die out, the inclination of the pendulum approaches  $90^\circ$  as a limit, even though the pendulum never (theoretically) stops its movements away from the perpendicular position. When we speak of the "limit" of a constant quantity, we shall mean the quantity itself.

By the *slope* of a line is meant the trigonometric tangent of the inclination of the line. Obviously, the slope of the secant  $PQ$  has for limit, as  $Q$  approaches  $P$ , the slope of the tangent at  $P$ . We shall first seek to make plausible, by arithmetic calculations, that the slope of the secant tends toward a limit as  $Q$  approaches  $P$ . Later, a rigorous treatment of the problem will be given.

If  $PM$  and  $QM$  are perpendicular to each other, (fig. 2), the slope of  $PQ$  is

$$\frac{QM}{PM} \quad (1)$$

Suppose that  $Q$  is the point (3, 9). As  $P$  is the point (2, 4),  $PM$  will be  $3-2=1$  and  $QM$  will be  $9-4=5$ . Then the slope of  $PQ$ , according to (1) above, will be 5. Let  $Q$  be the point (2.5, 6.25). Then  $PM=0.5$  and  $QM=2.25$ , so that  $PQ$  will have for slope  $2.25/0.5=4.5$ . If  $Q$  is (2.1, 4.41) the slope will be 4.1. It is thus a reasonable conjecture that, as  $Q$  approaches  $P$ , the slope of  $PQ$  approaches 4 as a limit, and that the slope of the tangent at  $P$  is 4. We will now give rigorous proof that the slope of the tangent at  $P$  is 4. We shall, for the sake of generality, deal with any point  $(x, y)$  on the parabola, rather than with the special point (2, 4).

Let  $P$  have the co-ordinates  $(x, y)$ . Let  $Q$  be any point on the parabola distinct from  $P$ . We shall represent the measures of  $PM$  and  $QM$  by the symbols  $\Delta x$  and  $\Delta y$  respectively. It should be noticed that  $\Delta x$ , for instance, is a single symbol, and does not stand for the product of two quantities,  $\Delta$  and  $x$ ; the symbol  $\Delta$  has no meaning by itself. The co-ordinates of  $Q$  will be  $x+\Delta x$  and  $y+\Delta y$ . The slope of  $PQ$  will be

$$\frac{\Delta y}{\Delta x}.$$

Our problem is to determine the limit of the ratio  $\Delta y/\Delta x$  as  $\Delta x$  approaches zero.

As  $\Delta x$  approaches zero, that is, as  $Q$  approaches  $P$ ,  $\Delta y$  also approaches zero. This, of course, does not mean that the quotient of  $\Delta y$  by  $\Delta x$  is small. For instance, in our calculations above, when  $\Delta x$  was 0.1 and  $\Delta y$  was 0.41,  $\Delta y/\Delta x$  was 4.1. As a matter of fact, when  $\Delta x$  and  $\Delta y$  are both small,  $\Delta y/\Delta x$  is very close to the slope of the tangent at  $P$ , which slope need not be a small number. *The idea contained in the last few lines is the central idea of the differential calculus.* We proceed to determine the limit of  $\Delta y/\Delta x$  as  $Q$  approaches  $P$ . As  $Q$  lies on the parabola, the ordinate of  $Q$  equals the square of its abscissa, that is,

$$y+\Delta y=(x+\Delta x)^2$$

$$\text{or} \quad y+\Delta y=x^2+2x \cdot \Delta x+(\Delta x)^2. \quad (2)$$

Now, as  $P$  has the co-ordinates  $(x, y)$ , and as  $P$  lies on the parabola, we have  $y=x^2$ . Using this fact in (2), we find that

$$\Delta y=2x \cdot \Delta x+(\Delta x)^2. \quad (3)$$

Dividing both sides of (3) by  $\Delta x$ , we have

$$\frac{\Delta y}{\Delta x}=2x+\Delta x. \quad (4)$$

We now bring  $Q$  closer and closer to  $P$ , thus making  $\Delta x$  smaller and smaller. It is plain, from (4), that  $\Delta y/\Delta x$  comes closer and closer to  $2x$ .

We have thus solved our problem. The tangent at any point  $P$  on the parabola has, for slope, twice the abscissa of  $P$ . Of course, this fact permits the immediate construction of the tangent at any point. When  $x=2$ , the slope of the tangent is 4. This is the result made reasonable above by arithmetic calculation. It should be appreciated that we have secured an exact, and not an approximate solution of the tangent problem. As  $Q$  approaches  $P$ , the slope of the secant approaches the slope of the tangent. But we have shown that the slope of the secant approaches  $2x$ . Hence the slope of the tangent must be identical with  $2x$ .

**Derivative.**—The solution of the tangent problem for the parabola has prepared the way for the introduction of the concept of derivative. Let  $y=f(x)$  be any function of  $x$ . Let the function be graphed as in fig. 3. We choose any value for  $x$ , and keep this value fixed during the discussion. To this fixed value of  $x$  cor-

FIG. 3.—DERIVATIVE

responds a fixed value of  $y$ . This gives a fixed point  $P$ , on the graph, of co-ordinates  $(x, y)$ . We take now any point  $Q$  on the graph, distinct from  $P$ , of co-ordinates  $(x+\Delta x, y+\Delta y)$ . As  $Q$  approaches  $P$ , the ratio  $\Delta y/\Delta x$  will, for the functions commonly met in mathematics, approach a definite limit, the slope of the tangent to the graph at  $P$ .

The limit of  $\Delta y/\Delta x$  is called the *derivative* of  $f(x)$  for the chosen value of  $x$ . Thus the derivative is nothing more than the slope of the tangent to the graph. We represent the derivative of the function  $y=f(x)$ , for any value of  $x$ , by the symbol

$$\frac{dy}{dx},$$

Thus, when  $y=x^2$ ,

$$\frac{dy}{dx}=2x.$$

As to each value of  $x$  there corresponds a definite value of  $dy/dx$ , the derivative is a function of  $x$ .

It cannot be emphasized too strongly that  $dy/dx$  is not a quotient. It is a number which is approached by a certain quotient, namely,  $\Delta y/\Delta x$ . The symbols  $dy$  and  $dx$ , as we are using them, have no meaning by themselves. The entire symbol,  $dy/dx$  represents, very expressively, the limit of  $\Delta y/\Delta x$ . It is true that, in one of the chapters of the calculus, "differentials" are defined, for which the symbols  $dy$  and  $dx$  are used. But the "differential" symbols are entirely distinct from the  $dy$  and  $dx$  used here.

The process of finding the derivative of a function is called *differentiation*. We have shown above how to differentiate  $x^2$ . In treatises on the calculus, it is shown how to differentiate all types of expressions. For instance, the derivative of  $x^n$  is proved to be  $nx^{n-1}$  for all values of  $n$ . For  $n$  a positive whole number, this is a very easy problem, and is handled as the case of  $x^2$  was handled above. The derivative of  $\sin x$  is  $\cos x$ , provided that  $x$  is measured in radians. The derivative of  $\log x$  is  $1/x$ , when the logarithms are taken to the so-called Naperian base  $e=2.718281 \dots$  (See LOGARITHMS.) The derivative of the sum of two functions is the sum of their derivatives. There exist simple rules for the differentiation of the product or the quotient of two functions.

If  $y$  is a constant, then, for every  $\Delta x$ ,  $y+\Delta y=y$ , so that  $\Delta y=0$ . Hence  $\Delta y/\Delta x$  is always zero, so that, according to the definition of the limit of a constant quantity,  $dy/dx$  is also zero. This is brought out geometrically by the fact that the graph of a constant is a horizontal line, so that the tangent to the graph at any point, which is the graph itself, has a zero slope. We see that two functions which differ by a constant, for instance,  $x^2$  and  $x^2+2$ , have the same derivative. This fact will be fundamental in connection with integration.

It has been said above that the quotient  $\Delta y/\Delta x$  approaches a limit for "the functions commonly met in mathematics." There exist functions, with more or less complicated definitions, for which no derivatives exist. For such functions, as  $\Delta x$  approaches zero, the quotient  $\Delta y/\Delta x$  either becomes infinite or oscillates without approaching a limit. The subject of functions which are without their derivatives forms a chapter in the theory of functions (q.v.).

**Rates.**—With the help of a problem mentioned above, we shall now proceed to develop the concept of instantaneous rate of change of a quantity varying with the time. Let water be introduced into an inverted hollow cone (fig. 4) at the uniform rate of 1 cu. ft./sec.

Let  $y$  be the depth of the water in the cone, measured in feet, after the water has been flowing in for  $t$  seconds. Then  $y$  is a function of  $t$ . To make this situation concrete, suppose that the angle between the extreme elements of the cone,  $OA$  and  $OB$ , is  $90^\circ$ . Then the radius of the upper surface of the water will always be

FIG. 4.—RATES

equal to  $y$ . Hence the volume of water in the cone at any instant is  $\frac{1}{3} \cdot \pi y^2 = \frac{1}{3} \pi y^3$  cu. feet. But, in  $t$  seconds,  $t$  cubic feet of water have entered the tank. Hence

$$\frac{1}{3} \pi y^3 = t,$$

$$y = \left( \frac{3t}{\pi} \right)^{\frac{1}{3}}.$$

What we shall do, according to the central principle of the theory of rates, is to use  $dy/dt$  for the rate of change of  $y$ . That is, the speed with which the level rises at any instant  $t$  ( $t$  seconds after the water begins to flow in) will be taken as the derivative of  $y$  at that instant. To justify this principle, let us consider any fixed instant  $t$ , and the depth  $y$  at that instant. At any later instant,  $t + \Delta t$ , the depth will have been increased by an amount  $\Delta y$ . Roughly speaking, one might say that, during the time  $\Delta t$ ,  $y$  has increased at the "average rate" of  $\Delta y/\Delta t$  ft. per sec., but we have no inherent notion of "average rate." What we are doing is to create a meaning for that term. A quantity  $y$ , increasing for  $\Delta t$  sec. at a uniform rate of  $\Delta y/\Delta t$  ft. per sec. would increase  $\Delta y$  ft. That is why it is natural to take  $\Delta y/\Delta t$  as an "average" in our case. Furthermore, if  $\Delta t$  is a very small period of time, the level of the water would appear to an observer to be rising practically uniformly, and practically at the rate  $\Delta y/\Delta t$ , during the time  $\Delta t$ .

Because  $\Delta y/\Delta t$  can be used as an average speed for the period  $\Delta t$ , and because  $\Delta y/\Delta t$  approaches  $dy/dt$  as  $\Delta t$  approaches zero, we define the *instantaneous rate of change* of  $y$ , at any instant  $t$ , to be  $dy/dt$ . Thus the instantaneous rate of change is primarily a mathematical notion.

Although the notion of instantaneous rate of change is a mathematical one, it is of the greatest utility in the applied sciences. For when a problem of applied science is to be subjected to mathematical analysis, what is done, effectively, is to replace the problem by an ideal mathematical problem, formulated in terms of the pure mathematician's concepts. To find  $dy/dt$  in the problem of the cone, let  $a$  represent  $(3/\pi)^{\frac{1}{3}}$ . Then

$$y = at^{\frac{1}{3}},$$

so that

$$y + \Delta y = a(t + \Delta t)^{\frac{1}{3}}.$$

Thus

$$\begin{aligned} \frac{\Delta y}{\Delta t} &= \frac{a(t + \Delta t)^{\frac{1}{3}} - at^{\frac{1}{3}}}{\Delta t} \\ &= a \frac{(t + \Delta t)^{\frac{1}{3}} - t^{\frac{1}{3}}}{(t + \Delta t) - t} \\ &= \frac{a}{(t + \Delta t)^{\frac{2}{3}} + (t + \Delta t)^{\frac{1}{3}}t^{\frac{1}{3}} + t^{\frac{2}{3}}} \end{aligned}$$

The last step is justified by the equation

$$u - v = (u^{\frac{1}{3}} - v^{\frac{1}{3}})(u^{\frac{2}{3}} + u^{\frac{1}{3}}v^{\frac{1}{3}} + v^{\frac{2}{3}}),$$

which can be verified by multiplication. As  $\Delta t$  approaches zero,  $t + \Delta t$  approaches  $t$ , so that  $\Delta y/\Delta t$  approaches

$$\frac{a}{3t^{\frac{2}{3}}},$$

which, then, is  $dy/dt$ . For instance, when  $t$  is 8 sec., the level is rising at  $a/12 = 0.08$  ft. per second.

**Maxima and Minima.**—Consider a function  $y = f(x)$  which has a derivative for every  $x$  (fig. 5). At a point such as  $A$ , at which the function is a maximum, or at a point such as  $B$ , where the function is a minimum, the tangent is horizontal; the slope of the tangent is zero.

To give rigorous proof of this fact, let the abscissa of  $A$  be  $a$ , and suppose that  $dy/dx$  is not zero for  $x = a$ . To fix our ideas, let us suppose that  $dy/dx$  is positive at  $a$ . When  $\Delta x$  is small,  $\Delta y/\Delta x$

FIG. 5.—MAXIMA AND MINIMA

is very nearly equal to  $dy/dx$ . Hence, for a small  $\Delta x$ ,  $\Delta y/\Delta x$  is positive, like  $dy/dx$ . Then, if  $\Delta x$  is small and positive,  $\Delta y$  must be positive, for, if  $\Delta y$  were zero or negative,  $\Delta y/\Delta x$  would be zero or negative. Hence a point on the graph somewhat to the right of  $A$  must have a greater ordinate than  $A$ , so that  $y$  cannot be a maximum for  $x = a$ . This absurdity shows that  $dy/dx = 0$  for  $x = a$ .

**Example.**—Suppose that we have a square sheet of tin, 6 in. on each side, that we cut a square of side  $x$  out of each corner, and fold up the sides so as to form an open box. The altitude of the box will be  $x$ , and its base will be a square of side  $6 - 2x$ . The volume of the box, call it  $y$ , will be

$$y = x(6 - 2x)^2 = 4x^3 - 24x^2 + 36x.$$

We find that

$$\frac{dy}{dx} = 12x^2 - 48x + 36,$$

so that, for a maximum,

$$12x^2 - 48x + 36 = 0.$$

This equation has the roots 1 and 3; that is, if there is an  $x$  for which  $y$  is a maximum,  $x$  is either 1 or 3. From the nature of the problem, it is evident that some  $x$  makes the volume a maximum. Certainly 3 is an impossible value for  $x$ . Hence, for  $x = 1$ , we get a box of maximum volume.

**Integral.**—If one function is the derivative of a second function, the second function is called an *integral* of the first. For instance,  $x^2$  is an integral of  $2x$ . We say an integral, rather than the integral, because  $2x$  has an infinite number of integrals. The functions  $x^2 + 2$ ,  $x^2 - 10$ , in short, all functions  $x^2 + c$ , with  $c$  a constant, are integrals of  $2x$ . This is because the derivative of a constant is zero for every  $x$ . If  $F(x)$  is an integral of  $f(x)$ , we write

$$F(x) = \int f(x) dx.$$

(We shall explain below the origin of this rather peculiar symbolism.) Thus,

$$\int 2x dx = x^2 + c, \text{ where } c \text{ is any constant.}$$

The fundamental question arises as to whether all integrals of a function are found by adding constants to any particular integral. The reply is affirmative. The only integrals of  $2x$ , for instance, are the functions  $x^2 + c$ , with  $c$  a constant. To give a geometric proof of this fact, let us observe that if  $F(x)$  has  $2x$  for derivative, then the function  $F(x) - x^2$  has a derivative which is everywhere zero. Now only a constant can have a derivative which is zero for every  $x$ , for if a function is not a constant, its graph must have points at which the tangent is not horizontal. Thus,  $F(x) - x^2 = c$ , with  $c$  constant, so that

$$F(x) = x^2 + c.$$

The process of finding the integral of a function is called *integration*. While the determination of the derivative of a function is a perfectly straightforward procedure, for which definite rules exist, there is no general method for finding the integral of a mathematical expression. Treatises on the calculus give rules for integrating large classes of functions. When these rules fail, more powerful methods can be used which do not give an expression for the integral, but which permit the value of the integral to be calculated for any value of  $x$  in which one may be interested. To find a formula for the distance through which a body falls in a given time, under the influence of gravity, let a body, initially at rest, be allowed to fall. If  $g$  is the acceleration of gravity, (32 ft./sec.<sup>2</sup>), the body will, in  $t$  seconds, acquire a speed of  $gt$  ft. per second. Let  $s$  be the distance through which the body falls in  $t$  seconds. Then

$$\frac{ds}{dt} = gt,$$

so that

$$s = \int gt dt.$$

Thus

$$s = \frac{gt^2}{2} + c.$$

To determine the constant  $c$ , we observe that  $s = 0$  when  $t = 0$ .

Then

$$o = \frac{g o^2}{2} + c,$$

so that  $c = 0$ . Hence,  $s = g t^2 / 2$  for every  $t$ .

**Areas.**—One of the most important applications of the integral calculus is the determination of the area under a curve. Let the curve in fig. 6 be the graph of the function  $y = f(x)$ . We are interested in determining the area enclosed by the curve, the  $Y$ -axis, the  $X$ -axis and the ordinate  $PM$ , where  $M$  is a point of any abscissa,  $x$ . It is clear that this area, call it  $A$ , is a function of  $x$ , the abscissa of  $M$ . We shall prove that

$$\frac{dA}{dx} = y. \quad (5)$$

where  $y$  is  $PM$ .

Suppose  $x$  is increased by an amount  $\Delta x$ . The increase,  $\Delta A$ , of  $A$ , is the strip  $PMM'P'$ . To fix our ideas, we shall assume that, between  $P$  and  $P'$  the graph rises. It will be seen that all other cases are treated in the same way. The strip  $\Delta A$  has a greater area than a rectangle of base  $\Delta x$  and height  $y$ , but has a smaller area than a rectangle of base  $\Delta x$  and height  $y + \Delta y$ . Thus  $\Delta A$  is greater than  $y\Delta x$  and less than  $(y + \Delta y)\Delta x$ . Hence  $\Delta A / \Delta x$  is greater than  $y$ , but less than  $y + \Delta y$ . But, as  $\Delta x$  approaches 0,  $\Delta y$  approaches 0, so that  $y + \Delta y$  decreases towards  $y$ . Hence  $\Delta A / \Delta x$ , which lies between  $y + \Delta y$  and  $y$ , must approach  $y$ . This proves (5).

We have thus

$$A = \int y dx.$$

To find, for example, the area under the parabola in fig. 2, we have

$$A = \int x^2 dx = \frac{x^3}{3} + c.$$

To determine  $c$ , we observe that  $A = 0$  when  $x = 0$ . This gives  $c = 0$ , so that  $A = x^3 / 3$ . The area problem is typical of a whole class of problems in geometry and physics. By quite the same means, we determine the lengths of curves, the volumes of solids, the moments of inertia of solids, and other quantities.

We can now point out the origin of the symbol for integration. Let the base  $OM$  in fig. 6 be divided into several segments, and rectangles like  $PM'$  be constructed on the segments. If the number of segments is very large, and each segment very small, the sum of the areas of the rectangles will be a very good approximation to the area under the curve. Let the segments become smaller and smaller, their number becoming larger and larger. Then the area under the curve will be the limit of a sum of rectangles, each rectangle having an area  $y \Delta x$ , where  $y$  is the altitude and  $\Delta x$  the base of the rectangle.

In the symbol  $\int y dx$ , the  $\int$ , a mediaeval  $S$ , stands for *summa* (sum). The  $dx$  refers to the bases  $\Delta x$  of the rectangles. Thus, the notation for integration arose out of the usefulness of the integral for determining the limits of sums.

The methods used by the Greeks for determining the area of a circle and of a segment of a parabola, and the volumes of the cylinder, cone and sphere, were, to the extent that they involved finding the limits of sums, akin to the method of integration. During the first half of the 17th century, methods of more or less limited scope began to appear among mathematicians for constructing tangents, determining maxima and minima, and finding areas and volumes. But it remained for Isaac Newton and Gottfried Wilhelm Leibniz, working independently of each other, to create during the latter half of the 17th century the concepts of derivative and integral. Newton regarded the derivative of a function as a speed at which the function changes. His symbol for the derivative of a function  $y$ , which he called the "fluxion" of the function, was  $\dot{y}$ . The methods of the calculus permitted Newton to carry out one of his finest investigations

that of the mechanics of the solar system. Leibniz used the notation  $dy/dx$  for the derivative, and also introduced the integration symbol.

During the past two and a half centuries numbers of theories have grown up which are offshoots of the calculus. One might mention differential equations, the calculus of variations, differential geometry (*qq.v.*); the theory of functions of complex variables, with its special chapters like elliptic functions and abelian integrals; the theory of functions of real variables, continuous groups, the calculus of finite differences and integral equations; see CALCULUS OF DIFFERENCES; FUNCTIONS; GROUPS, THEORY OF.

**BIBLIOGRAPHY.**—The following have been selected out of a great number: J. Edwards, *Calculus for Beginners*, 2 vols. (1906–22); A. E. H. Love, *Elements of the Differential and Integral Calculus* (1909); W. A. Granville, *Differential and Integral Calculus* (1911 and later editions); C. Love, *Differential and Integral Calculus* (1925). More advanced books, recently published are: J. Edwards, *Integral Calculus*, 2 vols. (1920–23); W. F. Osgood, *Advanced Calculus* (1925); H. B. Fine, *Calculus* (1927). Among the older works of interest are: I. Todhunter, *Treatise on the Differential Calculus and Treatise on the Integral Calculus* (1852, 1874); B. Price, *Infinitesimal Calculus*, 4 vols. (1854); J. Bertrand, *Traité de calcul différentiel et intégral*, 4 vols. (1855–89). (J. F. Rr.)

**CALCULUS OF DIFFERENCES** (Theory of Finite Differences), that branch of mathematics which deals with the successive differences of the terms of a series.

i. The subject falls under four main heads.

(i.) As a simple example, take the series

$$0, 1, 4, 9, 16 \dots,$$

which is the series of squares of the positive integers. If from each term of the series we subtract the preceding term, we get a new series

$$1, 3, 5, 7 \dots,$$

which is the series of odd positive integers. The terms of these series are the *first differences* of the terms of the original series. By a second set of subtractions we get the *second differences*, each of which is 2; and so on. We can put these in tabular form, thus:—

| No.       | 0 | 1 | 2 | 3 | 4  | 5  |
|-----------|---|---|---|---|----|----|
| Square.   | 0 | 1 | 4 | 9 | 16 | 25 |
| 1st diff. |   | 1 | 3 | 5 | 7  | 9  |
| 2nd diff. |   |   | 2 | 2 | 2  | 2  |
| 3rd diff. |   |   |   | 0 | 0  | 0  |

The first class of problems is concerned with the *summation of series*. Suppose that our original series, which we will call (A), is

$$(A) \quad 1, 3, 5, 7, 9 \dots,$$

the  $n$ th term being  $2n - 1$ ; and that we want to find the sum of the first  $n$  terms. By actual addition we get the successive sums, constituting a new series

$$(S) \quad 1, 4, 9, 16, 25 \dots$$

The form of this series suggests that the sum of  $n$  terms of (A) is  $n^2$ ; and this can be verified by mathematical induction (*q.v.*).

(ii.) We can express the above in a slightly different way by saying that there is a certain unknown series (S), which we want to find, and that our data are the first differences of this series, given in (A). Or, more briefly, we can say that the difference between the  $n$ th term of (S) and the  $(n+1)$ th term is  $2n+1$ . This is an example of a *difference-equation* (§10). In the notation explained below, the equation would be stated in the form

$$\Delta u_n = 2n + 1,$$

the quantity to be found being  $u_n$ .

(iii.) In the class of cases considered above we are concerned with a discontinuous series of terms, and we are limited to the consideration of this series or of the series derived from it by processes of differencing or summing. There is another class of cases in which our data are values of a continuously varying quantity, and our first object is to find intermediate values of this quantity. This process is *interpolation* (*q.v.*), which leads on to *quadrature* (*q.v.*). The importance of the calculus of differences

n relation to interpolation and quadrature arises from the fact that, if  $p$  is a positive integer, the difference between  $n^p$  and  $(n+1)^p$  is an expression in which the highest power of  $n$  is  $n^{p-1}$ ; so that, if  $n$  is a polynomial in  $x$ , the values of which are known for a series of integral values of  $x$ , the process of successive differencing of these values leads ultimately to a series of differences, all of which are 0.

(iv.) Underlying all these processes there are certain relations between terms and differences, which it is convenient to deal with first. The subject will accordingly be considered, though very briefly, under the heads (I.) Algebra of differences and sums; (II.) Sums of series; (III.) Difference-equations generally; (IV.) Relations applicable to interpolation; (V.) Relations applicable to quadrature. Applications of (IV.) and (V.) will be found under INTERPOLATION and MENSURATION respectively.

### I. ALGEBRA OF DIFFERENCES AND SUMS

2. Let  $p, q, r, s, t \dots$  be consecutive terms of a series. Then by successive subtractions we get the *first differences*  $q-p, r-q \dots$ , the *second differences*  $r-2q+p, s-2r+q \dots$ , and so on. These are also called *differences of the first, second, order*. It is convenient to arrange the terms in one column, and the successive differences in successive columns, as in Table I.

TABLE I.

| Term. | 1st diff. | 2nd diff. | 3rd diff.   | 4th diff.      |
|-------|-----------|-----------|-------------|----------------|
| $p$   | $q-p$     |           |             |                |
| $q$   | $r-q$     | $r-2q+p$  |             |                |
| $r$   | $s-r$     | $s-2r+q$  | $s-3r+3q-p$ |                |
| $s$   | $t-s$     | $t-2s+r$  | $t-3s+3r-q$ | $t-4s+6r-4q+p$ |
| $t$   |           |           |             |                |

It will be noticed that the coefficients in the successive columns of differences are those of the powers of  $y$  in  $y-1, (y-1)^2, (y-1)^3, \dots$ . For considering relations of this kind we need a special notation.

3. **Systems of Notation.**—We shall denote the terms of the series by  $\dots u_0, u_1, u_2 \dots$ , the suffixes 0, 1, 2  $\dots$  merely indicating the position of the term in the series. If the series begins with a definite term, we usually call this  $u_0$  or  $u_1$ , according to circumstances. But in a good many cases there is no first term, the series being capable of continuation backwards as well as forwards. Thus in the example given in §1(i.) we could introduce the squares of negative integers as well as those of positive integers, and the series would then be:—

|               |    |    |    |   |   |         |
|---------------|----|----|----|---|---|---------|
| No. . . . .   | -2 | -1 | 0  | 1 | 2 | 3 . . . |
| Square . . .  | 4  | 1  | 0  | 1 | 4 | 9 . . . |
| 1st diff. . . |    | -3 | -1 | 1 | 3 | 5 . . . |

so that the differences would be the odd numbers, negative and positive.

The difference of two consecutive  $u$ 's can then be denoted by  $\Delta u$ ; the difference of two consecutive differences by  $\Delta^2 u$ , or, for shortness,  $\Delta^2 u$ ; and so on. But we again need a system of suffixes to indicate where a particular difference comes. Now, in §2, the expression  $q-p$  contains  $p$  and  $q$ , and it might be regarded as the first difference either of  $p$  or of  $q$ . On the one system the quantity  $t-4s+6r-4q+p$  would be the fourth difference of  $p$ ; on the other system it would be the fourth difference of  $t$ . Or, since the term which has the greatest coefficient in this quantity is  $r$ , the quantity might be regarded as the fourth difference of  $r$ . These three possible ways of regarding the matter lead to three different systems of notation, which are called the *advancing-difference*, the *receding-difference*, and the *central-difference* systems, respectively. We need only consider the first and the third of these.

4. **Advancing-difference Notation.**—In the *advancing-difference* notation we regard  $u_{n+1}-u_n$  as the first difference of  $u_n$ , and give to this value of  $\Delta u$  the suffix  $n$ , i.e., we have

$$\Delta u_n \equiv u_{n+1} - u_n.$$

Similarly  $\Delta u_{n+1} - \Delta u_n$  is the first difference of  $\Delta u_n$ ; i.e.,

$$\Delta^2 u_n \equiv \Delta \Delta u_n \equiv \Delta u_{n+1} - \Delta u_n = u_{n+2} - 2u_{n+1} + u_n;$$

and so on. Thus our table of terms and differences becomes Table II.

TABLE II.

| Term.     | 1st diff.        | 2nd diff.          | 3rd diff.          | 4th diff.          |
|-----------|------------------|--------------------|--------------------|--------------------|
| $\vdots$  | $\vdots$         | $\vdots$           | $\vdots$           | $\vdots$           |
| $u_n$     | $\Delta u_n$     | $\Delta^2 u_{n-1}$ | $\Delta^3 u_{n-1}$ | $\Delta^4 u_{n-2}$ |
| $u_{n+1}$ | $\Delta u_{n+1}$ | $\Delta^2 u_n$     | $\Delta^3 u_n$     | $\Delta^4 u_{n-1}$ |
| $u_{n+2}$ | $\Delta u_{n+2}$ | $\Delta^2 u_{n+1}$ | $\Delta^3 u_{n+1}$ | $\Delta^4 u_n$     |
| $u_{n+3}$ | $\Delta u_{n+3}$ | $\Delta^2 u_{n+2}$ | $\Delta^3 u_{n+2}$ | $\Delta^4 u_{n+1}$ |
| $u_{n+4}$ | $\vdots$         | $\Delta^2 u_{n+3}$ | $\vdots$           | $\Delta^4 u_{n+2}$ |
| $\vdots$  | $\vdots$         | $\vdots$           | $\vdots$           | $\vdots$           |

5. **Separation of Symbols of Operation.**—We can regard  $\Delta u_n$  as the result of a certain operation performed on  $u_n$ , just as  $5A$  denotes the result of the operation of multiplying  $A$  by 5, i.e., of changing  $A$  into 5 times  $A$ . The operation of changing  $u_n$  to  $\Delta u_n$  consists of two steps: (a) changing  $u_n$  to  $u_{n+1}$ , (b) subtracting  $u_n$  from the result. We use the symbol  $E$  to denote the first of these two steps, i.e.,

$$Eu_n \equiv u_{n+1}. \quad (2)$$

We then have

$$\Delta u_n = Eu_n - u_n, \quad Eu_n = u_n + \Delta u_n. \quad (3)$$

The important property of these symbols is that, like numerical coefficients, they can be detached from the term on which they operate and can be dealt with according to the laws of ordinary algebra, as if they were numbers. Thus, if we wish we may write (3) as follows:

$$\Delta = E - 1, \quad E = 1 + \Delta. \quad (4)$$

As an example of the application of the property mentioned above, we have

$$\begin{aligned} \Delta^n u_0 &= (E-1)^n u_0 \\ &= \left\{ E^n - \frac{n}{1} E^{n-1} + \frac{n(n-1)}{1 \cdot 2} E^{n-2} \dots + (-1)^n 1 \right\} u_0 \\ &= u_n - \frac{n}{1} u_{n-1} + \frac{n(n-1)}{1 \cdot 2} u_{n-2} \dots + (-1)^n u_0. \end{aligned} \quad (5)$$

This is the relation mentioned at the end of §2. Similarly we find that

$$\begin{aligned} u_n &= E^n u_0 = (1 + \Delta)^n u_0 \\ &= \left\{ 1 + \frac{n}{1} \Delta + \frac{n(n-1)}{1 \cdot 2} \Delta^2 + \dots + \Delta^n \right\} u_0 \\ &= u_0 + \frac{n}{1} \Delta u_0 + \frac{n(n-1)}{1 \cdot 2} \Delta^2 u_0 + \dots + \Delta^n u_0. \end{aligned} \quad (6)$$

This relation is of importance for the purpose of finding the sums of certain series (see §9).

6. **Summation.**—Now, taking the table in §4, let us continue it backwards, i.e., let us regard the  $u$ 's as the first differences of the terms of another series, which we will call  $\dots \Sigma u_n, \Sigma u_{n+1} \dots$ . Then for consistency of notation we see that  $u_n$  must come between  $\Sigma u_n$  and  $\Sigma u_{n+1}$ , i.e.,

$$u_n = \Sigma u_{n+1} - \Sigma u_n, \quad u_{n+1} = \Sigma u_{n+2} - \Sigma u_{n+1}, \dots \quad (7)$$

Thus we get Table III. Similarly, we can insert further columns containing  $\Sigma^2 u_n$ , etc.

TABLE III

| $\Sigma u$       | $u$       | $\Delta u$       | $\Delta^2 u$       | ... |
|------------------|-----------|------------------|--------------------|-----|
| $\vdots$         | $\vdots$  | $\vdots$         | $\vdots$           |     |
| $\Sigma u_n$     | $u_n$     |                  |                    |     |
| $\Sigma u_{n+1}$ | $u_{n+1}$ | $\Delta u_n$     | $\Delta^2 u_n$     |     |
| $\Sigma u_{n+2}$ | $u_{n+2}$ | $\Delta u_{n+1}$ | $\Delta^2 u_{n+1}$ | ... |
| $\Sigma u_{n+3}$ | $u_{n+3}$ | $\Delta u_{n+2}$ | $\Delta^2 u_{n+2}$ | ... |
| $\vdots$         | $\vdots$  | $\vdots$         | $\vdots$           |     |

If we only know the  $u$ 's, we cannot find the new series completely; for the accuracy of the above table is not affected by adding a constant  $k$  to each term of the  $\Sigma u$  series. But, when we have found a particular term of this series, say  $\Sigma u_i$ , the other terms are also fixed. By (7) we then have

$$\Sigma u_2 = \Sigma u_1 + u_1, \quad \Sigma u_3 = \Sigma u_1 + u_1 + u_2 \dots \quad (8)$$

$$\Sigma u_n = \Sigma u_1 + u_1 + u_2 + \dots + u_{n-1}$$

$$\text{and also} \quad \Delta \Sigma u_n = \Sigma u_{n+1} - \Sigma u_n = u_n. \quad (9)$$

The relation between the operators  $\Delta$  and  $\Sigma$  may be written in either of the forms

$$\Delta \Sigma = 1, \quad \Sigma \Delta = 1. \quad (10)$$

It should be observed that  $\Sigma u_n$  does not include  $u_n$ ; it only goes as far as  $u_{n-1}$ .

Until we know a term of the  $\Sigma u$  series, we must leave the actual terms indefinite, their first differences being definite. Thus we can write

$$\Sigma u_n = C + u_{n-3} + u_{n-2} + u_{n-1},$$

where  $C$  is an "arbitrary constant"; and we shall then have, with the same value of  $C$ ,

$$\Sigma u_{n+1} = C + u_{n-3} + u_{n-2} + u_{n-1} + u_n,$$

and so on.

**7. Central-difference Notation.**—The *central-difference* notation differs from the *advancing-difference* in two respects: (i.) the assignment of suffixes, (ii.) the introduction of a symbol to denote the operation of taking the mean.

The main principle, as indicated in §3, is that  $u_{n+2} - 2u_{n+1} + u_n$  is regarded as the second difference not of  $u_n$  but of  $u_{n+1}$ ; it is denoted by  $\delta^2 u_{n+1}$ . The first difference  $u_{n+1} - u_n$  is therefore  $\delta u$ , with a proper suffix; and this suffix, for symmetry, must be  $n + \frac{1}{2}$ . Thus we have

$$\delta u_{n+\frac{1}{2}} \equiv u_{n+1} - u_n, \quad \delta^2 u_n \equiv \delta u_{n+\frac{1}{2}} - \delta u_{n-\frac{1}{2}} \\ = u_{n+1} - 2u_n + u_{n-1}, \text{ etc.} \quad (11)$$

On the same principle the entries in the column preceding the  $u$  column will be  $\sigma u$ , with proper suffixes; and we have

$$u_n = \sigma u_{n+\frac{1}{2}} - \sigma u_{n-\frac{1}{2}}, \text{ etc.,}$$

so that the operations  $\delta$  and  $\sigma$  are connected by the relation

$$\delta \sigma = 1, \quad \sigma \delta = 1. \quad (12)$$

Our table, from the  $\sigma^2 u$  column to the  $\delta^2 u$  column, becomes Table IV.

TABLE IV.

| $\sigma^2 u$       | $\sigma u$                 | $u$       | $\delta u$                 | $\delta^2 u$       |
|--------------------|----------------------------|-----------|----------------------------|--------------------|
| $\vdots$           | $\vdots$                   | $\vdots$  | $\vdots$                   | $\vdots$           |
| $\sigma^2 u_{n-2}$ |                            | $u_{n-2}$ |                            | $\delta^2 u_{n-2}$ |
|                    | $\sigma u_{n-\frac{3}{2}}$ |           | $\delta u_{n-\frac{3}{2}}$ |                    |
| $\sigma^2 u_{n-1}$ |                            | $u_{n-1}$ |                            | $\delta^2 u_{n-1}$ |
|                    | $\sigma u_{n-\frac{1}{2}}$ |           | $\delta u_{n-\frac{1}{2}}$ |                    |
| $\sigma^2 u_n$     |                            | $u_n$     |                            | $\delta^2 u_n$     |
|                    | $\sigma u_{n+\frac{1}{2}}$ |           | $\delta u_{n+\frac{1}{2}}$ |                    |
| $\sigma^2 u_{n+1}$ |                            | $u_{n+1}$ |                            | $\delta^2 u_{n+1}$ |
|                    | $\sigma u_{n+\frac{3}{2}}$ |           | $\delta u_{n+\frac{3}{2}}$ |                    |
| $\sigma^2 u_{n+2}$ |                            | $u_{n+2}$ |                            | $\delta^2 u_{n+2}$ |
| $\vdots$           | $\vdots$                   | $\vdots$  | $\vdots$                   | $\vdots$           |

**8. Operation of Taking the Mean.**—We introduce the symbol  $\mu$  to denote the operation of taking the mean of two adjacent quantities in a column, the suffix, like that of  $\delta$ , being the mean of their suffixes. Thus

$$\mu u_{n+\frac{1}{2}} \equiv \frac{1}{2}(u_n + u_{n+1}), \quad \mu \delta u_n \equiv \frac{1}{2}(\delta u_{n+\frac{1}{2}} + \delta u_{n-\frac{1}{2}}), \text{ etc.} \quad (13)$$

These means may be called the *constructed central differences*. If they are introduced, in brackets, into Table IV., we get the complete central-difference table of which Table V. is a part.

TABLE V.

| $\sigma^2 u$                       | $\sigma u$                 | $u$                       | $\delta u$                 | $\delta^2 u$                       |
|------------------------------------|----------------------------|---------------------------|----------------------------|------------------------------------|
| $\vdots$                           | $\vdots$                   | $\vdots$                  | $\vdots$                   | $\vdots$                           |
| $\sigma^2 u_n$                     | $(\mu \sigma u_n)$         | $u_n$                     | $(\mu \delta u_n)$         | $\delta^2 u_n$                     |
| $(\mu \sigma^2 u_{n+\frac{1}{2}})$ | $\sigma u_{n+\frac{1}{2}}$ | $(\mu u_{n+\frac{1}{2}})$ | $\delta u_{n+\frac{1}{2}}$ | $(\mu \delta^2 u_{n+\frac{1}{2}})$ |
| $\sigma^2 u_{n+1}$                 | $(\mu \sigma u_{n+1})$     | $u_{n+1}$                 | $(\mu \delta u_{n+1})$     | $\delta^2 u_{n+1}$                 |
| $\vdots$                           | $\vdots$                   | $\vdots$                  | $\vdots$                   | $\vdots$                           |

It is obvious that

$$\left. \begin{aligned} \sigma u_{n+\frac{1}{2}} &= C + u_{n-3} + u_{n-2} + u_{n-1} + u_n \\ \mu \sigma u_n &= C + u_{n-3} + u_{n-2} + u_{n-1} + \frac{1}{2}u_n \end{aligned} \right\} \quad (14)$$

where  $C$  is an arbitrary constant which remains the same throughout any series of operations.

## II. SUMMATION OF SERIES

9. For summation of series, and for difference-equations generally, the advancing-difference notation is usually the more suitable. There are two useful methods.

(i.) Suppose we want to find the value of such a sum as  $1^2 + 2^2 + 3^2 + \dots + n^2$ . Let us denote this sum by  $S_n$ . Then we see that

$$\Delta S_{n-1} = S_n - S_{n-1} = n^2, \quad \Delta^2 S_{n-2} = n^2 - (n-1)^2 = 2n-1, \\ \Delta^3 S_{n-3} = \Delta^2 S_{n-2} - \Delta^2 S_{n-3} = 2, \quad \Delta^4 S_{n-4} = 0.$$

Thus the fourth and higher differences of the  $S$ 's are all 0. Now construct the table of differences (Table VI.).

TABLE VI.

| $m$      | $S_m$    | $\Delta S_m$ | $\Delta^2 S_m$ | $\Delta^3 S_m$ | $\Delta^4 S_m$ |
|----------|----------|--------------|----------------|----------------|----------------|
| 0        | 0        | 1            |                |                |                |
| 1        | 1        | 4            | 3              |                |                |
| 2        | 5        | 9            | 5              | 2              | 0              |
| 3        | 14       | 16           | 7              | 2              | 0              |
| 4        | 30       | 25           | 9              | 2              | 0              |
| $\vdots$ | $\vdots$ | $\vdots$     | $\vdots$       | $\vdots$       | $\vdots$       |
| $n$      | $S_n$    |              |                |                |                |

Then, applying formula (6), we have

$$S_n = 0 + n(1) + \frac{1}{2}n(n-1)(3) + \frac{1}{6}n(n-1)(n-2)(2) \\ = \frac{1}{6}n(n+1)(2n+1).$$

(ii.) Another method is to express  $n^2$  as the sum of two or more expressions which can be easily summed. We can write  $n^2 = n(n+1) - n$ ; and the sum we require is therefore  $\frac{1}{2}n(n+1)(n+2) - \frac{1}{2}n(n+1) = \frac{1}{6}n(n+1)(2n+1)$ .

## III. DIFFERENCE-EQUATIONS

10. In the method of §9 (ii.) we are really solving a difference-equation

$$\Delta S_{n-1} = n^2$$

by writing the solution in the form

$$S_{n-1} = \Delta^{-1} n^2$$

and expressing  $n^2$  as the sum of two terms, on each of which the

operation  $\Delta^{-1}$  is easily performed. The above is an example of a difference-equation. Another simple form is

$$(E-a)u_n=0,$$

where  $a$  is a constant. This is equivalent to  $u_{n+1}=au_n$ , so that the solution is obviously

$$u_n=Ca^n,$$

where  $C$  is an arbitrary constant. A more general form is the linear equation with constant coefficients

$$u_{n+p}+a_1u_{n+p-1}+a_2u_{n+p-2}+\dots+a_pu_n=N,$$

where  $a_1, a_2, \dots, a_p$  are constants, and  $N$  is a given function of  $n$ .

#### IV. RELATIONS APPLICABLE TO INTERPOLATION

11. For interpolation, where  $u$  is a continuously varying function of  $x$ , and values of  $u$  are tabulated at intervals  $h$  in  $x$ , the relations between differences of the  $u$ 's and differential coefficients of  $u$  are important. The values of  $x$  for which  $u$  is tabulated are taken to be  $\dots x_{-1}, x_0, x_1, \dots$ , where  $x_p \equiv x_0 + ph$ .

If the differential coefficient of  $u$  with regard to  $x$  is denoted by  $Du$ , we may regard  $D$  as an operator; and it will be found that this can be combined with the operators  $\Delta, E$ , etc., and with numbers, according to the laws of ordinary algebra. Taylor's Formula (see CALCULUS, INTEGRAL AND DIFFERENTIAL),

$$f(x+h) = f(x) + hf'(x) + \frac{h^2}{2!}f''(x) + \dots \quad (15)$$

then leads to the relation

$$E = 1 + hD + \frac{h^2}{2!}D^2 + \frac{h^3}{3!}D^3 + \dots \quad (16)$$

$$= e^{hD};$$

whence we deduce

$$hD = \log_e(1+\Delta) = \Delta - \frac{1}{2}\Delta^2 + \frac{1}{3}\Delta^3 - \dots \quad (17)$$

This gives the first derivative in terms of advancing differences, namely,

$$h\left(\frac{du}{dx}\right)_0 = \Delta u_0 - \frac{1}{2}\Delta^2 u_0 + \frac{1}{3}\Delta^3 u_0 - \dots; \quad (18)$$

and formulae for the second and higher derivatives may be obtained from (17) by expanding the corresponding powers of  $\Delta - \frac{1}{2}\Delta^2 + \frac{1}{3}\Delta^3 - \dots$ .

Ordinarily the formulae which involve central differences are more useful. These formulae are based on the relations,

$$\mu = \frac{1}{2}(e^{\frac{1}{2}hD} + e^{-\frac{1}{2}hD}), \quad \delta = e^{\frac{1}{2}hD} - e^{-\frac{1}{2}hD}. \quad (19)$$

Expanding and combining these, we get expressions for  $\mu, \delta, \mu\delta$ , etc., in terms of  $hD$ ; and thence we deduce expressions for  $hDu$ , etc., in terms of the relevant central differences, original or constructed.

If in (15) we replace  $h$  by  $\theta h$ , and  $f(x+\theta h)$  by  $u_\theta$ , we can write it in the form

$$u_\theta = u_0 + c_1\theta + \frac{c_2}{2!}\theta^2 + \frac{c_3}{3!}\theta^3 + \dots \quad (20)$$

where

$$\begin{aligned} c_1 &= hDu_0 = (\mu\delta - \frac{1}{6}\mu\delta^3 + \frac{1}{30}\mu\delta^5 - \dots)u_0 \\ c_2 &= h^2D^2u_0 = (\delta^2 - \frac{1}{12}\delta^4 + \frac{1}{90}\delta^6 - \dots)u_0 \\ c_3 &= h^3D^3u_0 = (\mu\delta^3 - \frac{1}{4}\mu\delta^5 + \dots)u_0 \\ c_4 &= h^4D^4u_0 = (\delta^4 - \frac{1}{8}\delta^6 + \dots)u_0 \\ &\vdots \\ &\vdots \end{aligned} \quad (21)$$

This formula enables us to interpolate on both sides of  $u_0$  by using the central differences which are in a line with  $u_0$ . (The values of the  $c$ 's are given more fully under INTERPOLATION.) There is a formula of the same kind for interpolating between  $x=x_0$

and  $x=x_1$  in terms of  $\mu u_{\frac{1}{2}}$  and the central differences which are in a line with it.

#### V. RELATIONS APPLICABLE TO QUADRATURE

12. Just as under the heading Interpolation we deal with the relations between differential coefficients and differences, so under Quadrature we deal with the relations between integrals and sums. The main problem is that of expressing the area of a figure (of the kind with which we are familiar in dealing with graphs) in terms of selected ordinates of the figure. We can, however, reverse the process, and express the sum of a series, accurately or approximately, in terms of an integral. The important theorem is the Euler-Maclaurin theorem, given under MENSURATION.

BIBLIOGRAPHY.—Geo. Boole, *Treatise on the Calculus of Finite Differences* (2nd ed., J. F. Moulton, 1872); N. E. Nörlund, *Differenzenrechnung* (1924, bibl.). An elementary treatment will be found in most books dealing with INTERPOLATION (q.v.). (W. F. S.)

**CALCULUS OF VARIATIONS.** When two points, A and B, are given in a plane, as shown in fig. 1, there is an infinity of arcs which join them. A simple problem of the calculus of variations is that of finding in this class of arcs one which has the shortest length, the solution of the problem being of course a straight line segment. But we may also seek to find in the class of arcs joining A with B one down which a particle, started with a given initial velocity  $v$ , will fall in the shortest time from A to B; or we may ask which one of these arcs, when rotated about the axis Ox, will generate a surface of revolution of smallest area. These are typical problems of the calculus of variations of the so-called simplest type.

The notations which gave rise to the name, the calculus of variations, were originated by Joseph Louis Lagrange about the year 1762 and are still in use, though at the present time there is a tendency to replace them by others. If  $T$  represents the time of descent of a particle falling along an arc  $E$ , then to get the corresponding time for a neighbouring arc  $E'$  a correction must be added to  $T$ . This correction is called a variation of  $\delta T$  and is designated in Lagrange's notation by  $\delta T$ . Similarly the vertical distances  $y$  in fig. 1 corresponding to the various points of  $E$  must be corrected by variations  $\delta y$  in order to get the corresponding vertical distances for  $E'$ . The problem of finding an arc  $E$  such that the variation  $\delta T$  will be positive for all choices of the variations  $\delta y$  is the problem of the curve of quickest descent mentioned in the last paragraph. Since the time of Lagrange the theory of such problems has been called the calculus of variations.

**The Shortest Line from a Point to a Curve.**—Some of the properties of minimizing arcs of the calculus of variations are well illustrated by the problem of determining the shortest line joining a fixed point A with a fixed curve C, shown in fig. 2. Evidently the solution of the problem must be a straight segment AB, and it can further readily be seen that AB must cut the fixed curve C at right angles. For if C were in the position C' shown in fig. 2 the line AQ would evidently be shorter than AB.

It might be concluded that a straight line AB perpendicular to C is actually the shortest line joining A to C, but this is not always true. It is known that the straight lines cutting C at right angles are all tangent to a curve D, as shown in fig. 3, one of whose properties is that the length of the composite arc PQR is always equal to the length PB, whatever the position of Q at the right of P on D. This is the well-known string property of the curve D, so-called because it means that a stretched string of length PB, attached at P and allowed to wrap itself around the curve D, will describe the arc C with its movable end R. The length of the composite arc APQR is equal to that of AB, as has just been indicated, and the length of APQR will be less than that of AB when the curved arc PQ is replaced by a straight line. Evidently AB is not the shortest arc which can be drawn from A to the curve C

FIG. 1

FIG. 2

if its point of contact P with the envelope D lies between A and B.

It is conceivable that other properties might be required of the segment AB in order to insure its minimizing property. But it can be proved, when the point A lies to the right of P in fig. 3, that there is a neighbourhood of AB in which that line is shorter than any other arc joining A with C.

**The Surface of Revolution of Minimum Area.**—The properties which have just been described for the shortest line AB from a point A to a curve C, namely, its straightness, its perpendicularity to C, and the absence from AB of a contact point P with the envelope D, are all analogues of properties which are possessed by minimizing arcs for other problems. There are, furthermore, sufficiency proofs, analogous to that mentioned in the last paragraph, which tell us when enough properties have been secured to insure the minimum property.

FIG. 3

A circular wire dipped in a soap solution and then withdrawn will have a disc of soap film stretched across it. If a smaller circular wire is made to touch this disc and is then withdrawn to a position shown in fig. 4 a film will be stretched between the two wires which is a surface of revolution about the common axis of the two circles. It is found by experiment that when the circle B is moved away from A in the direction of the dotted axis a position is presently reached at which the film always becomes unstable. It contracts at the waist and separates into two plane discs through the two circles.

The determination of the shape of the soap film described in the last paragraph gives rise to a perfectly definite mathematical problem. It is that of finding among the arcs joining A with B, in the plane of the paper in fig. 4, one which when rotated about the dotted axis will generate a surface of revolution of smallest area. The curve which solves the problem is described by a mathematical equation, but its shape is that of a chain whose ends are fast but which otherwise hangs freely. The mathematicians call such a curve a *catenary* from the Latin word *catena* meaning a chain.

FIG. 4

The catenaries of the problem which pass through the point A have an enveloping curve D as shown in fig. 5. The critical point on one of them, beyond which its minimizing property ceases, is its point of tangency P with the envelope. A very interesting property of the curves in fig. 5 is that the surface of revolution generated by the composite arc AQP is always equal to that generated by the catenary AP whatever the position of Q below P on the envelope. This is the analogue of the string property of the envelope of the straight lines perpendicular to a curve, and an argument similar to the one described for that case shows that the area of the surface of revolution generated by a catenary arc APB can never be a minimum area, since the areas of the surfaces generated by the arcs AQP and B are all equal to it.

When the point B lies above the envelope D there are always two catenary arcs joining it to A, as shown in fig. 5, one of which has a critical point P on it. The other is the one which can be proved to furnish a minimum area. When B lies in the position B<sub>1</sub>, then there is no catenary arc joining the points A and B and the minimum surface of revolution consists of the two discs generated by the broken line AMNB<sub>1</sub>.

FIG. 5

When the circular wire B in fig. 4 is moved away from A the catenary arc AB varies from one to another of the catenary arcs through A shown in fig. 5. The moment when the film decomposes into two discs, like those generated by the broken line AMNB<sub>1</sub>, is the moment when B reaches the enveloping curve D.

**Isoperimetric and Other Problems.**—The ancient Greeks proposed the problem of determining in the class of all closed arcs of a given length one which encloses the largest area. They called this the isoperimetric problem, from *isos* meaning equal and *περιμετρον* meaning circumference, and were able to show in more or less rigorous fashion that the curve which solves the problem is a circle.

The isoperimetric problem of the Greeks imposes an additional property besides closure on the arcs of the class in which the minimizing arc is sought, namely, that all of them shall have the same length. Similar restrictions may be put upon the class of arcs joining the points A and B described in the first paragraph of this article.

In the class of closed surfaces enclosing a given volume the one which has a minimum surface is a sphere. This agrees with the commonly observed fact that a soap bubble, enclosing a given volume of air, has spherical form. If, on the other hand, we turn the problem around and search in the class of closed surfaces having a given area, one which encloses a maximum volume, the solution is again a sphere. Every isoperimetric problem has associated with it in this way another one of the same sort and having the same solution surface or curve.

**Relation to Mechanics.**—In the domain of mechanics the calculus of variations has played an important rôle. If a system of particles is moving subject to their own gravitational attractions it is found that their paths will be minimizing curves for what the mathematicians call the integral of the difference between the kinetic and potential energies of the system. This is the famous principle known after its discoverer Sir William Rowan Hamilton as Hamilton's principle. Many most important trajectories of widely varying character in mechanics, astronomy and mathematical physics have similar maximum or minimum properties. The theory of the calculus of variations has been greatly enriched as a result of applications of this sort, and in turn it has been profoundly influential in shaping the mathematical interpretations of physical phenomena. Two striking illustrations in recent years are the famous relativity theory of Albert Einstein and the quantum theory of E. Schrödinger, both of which depend intimately upon portions of the theory of the calculus of variations.

The problems which have been described above are a few only of the large variety with which the calculus of variations is concerned. By the use of the devices of mathematical analysis the scope of the theory has been steadily enlarged. Great progress has been made, for example, in generalizing the character of the restrictions upon the classes of curves and surfaces in which minimizing elements are sought, as compared with the restrictions which have long been imposed for isoperimetric problems, and in generalizing the variable quantity dependent upon the curves or surfaces whose maximum or minimum value is to be obtained. The questions which have arisen are many of them only imperfectly answered and it is apparent to a student of the subject that the theory of the calculus of variations will always be a lively and growing one.

**A Historical Sketch.**—Some of the problems of the calculus of variations are very old. The isoperimetric problems of the circle and sphere were considered by Zenodorus (about 100 B.C.) and Archimedes (287?–212 B.C.). The problem of the curve of quickest descent appears somewhat vaguely in the writings of Galileo Galilei in 1630 and 1638, and was reformulated and solved by Jean (Johann, John) Bernoulli in 1696–97. The determination of the form of a hanging chain is a problem of the calculus of variations also considered by Galileo in 1638, reformulated by Jacques (Jakobs James) Bernoulli in 1690, and solved by Gottfried Wilhelm Leibniz and others in 1691. Isaac Newton determined in 1686 the characteristic property of a curve generating a surface of revolution offering minimum resistance to motion through a resisting medium in the direction of its axis.

All of these were special problems solved by special methods. The foundations for a general theory were laid by Jacques Bernoulli in his solution in 1697 of the problem of the curve of quickest descent which had been proposed by his brother Jean. Leon-

hard Euler saw that the methods of Jacques Bernoulli were widely applicable and he deduced in 1744 the first general rule for the characterization of maximizing or minimizing arcs of the calculus of variations. In 1760–62 Lagrange devised the notations for variations which have given the theory its name, and greatly simplified and extended the results of Euler. In 1786 Adrien Marie Legendre studied for the first time what is called the second variation of the quantity to be minimized and found a criterion for distinguishing between maxima and minima. In his reduction of the second variation Legendre used a transformation which could not be justified in all cases. The difficulty was analysed in 1838 by Carl Gustav Jacob Jacobi, who in so doing discovered the existence of the critical point  $P$  beyond which the minimizing properties of an arc will fail.

The modern period in the development of the theory of the calculus of variations is characterized by much greater precision in the formulation of problems and in the methods and reasoning applied to their solution. It began with Karl Weierstrass, who in the decade preceding 1879 saw that one might continue indefinitely to seek for properties of minimizing arcs unless a proof could be made that a suitable set of properties would actually insure the minimum. He had himself found an important new necessary condition for a minimum which cannot easily be described here in non-technical language. He succeeded in proving in very ingenious fashion that certain characteristics of an arc are sufficient to insure its minimizing property. Between 1894 and 1898 the string property of the envelope of the normals to a curve was generalized for shortest lines on a surface by Jean Gaston Darboux, and for more general problems by E. Zermelo and Adolf Kneser. In 1899 David Hilbert stated an existence theorem which asserts that under certain circumstances a minimizing arc will surely exist. The theorem has been reproved more simply by other writers and extended by Leonida Tonelli, who in 1921–23 made it the basis for a new approach to the theory of the calculus of variations. The scope of the theory of the calculus of variations has been greatly extended by Adolf Mayer and Oskar Bolza, who formulated in 1878 and 1913, respectively, problems of very great generality to which the methods of the theory are applicable. For further historical data and accounts of the views of modern mathematicians on the subject, the reader should consult the references in the Bibliography.

**BIBLIOGRAPHY.**—For a relatively elementary introduction to the calculus of variations one may read Edouard Goursat, *Cours d'Analyse Mathématique*, vol. iii. 3rd ed. pp. 545–660 (Gauthier-Villars 1923), or Gilbert Ames Bliss, *The Calculus of Variations* (Open Court Publishing Co., Chicago, 1925). The most thorough presentations of modern theories are O. Bolza, *Lectures on the Calculus of Variations* (University of Chicago Press, 1904), and *Vorlesungen über Variationsrechnung* (Teubner, Leipzig, 1909); Jacques Hadamard, *Leçons sur le Calcul des Variations* (A. Hermann, 1910); and A. Kneser, *Lehrbuch der Variationsrechnung*, 2nd ed. (Vieweg, Braunschweig 1925). L. Tonelli, *Calcolo delle Variazioni* (Zanichelli, Bologna, 1921, 1923), makes existence theorems the basis of a new attack upon the theory requiring analysis of the most modern sort.

For an excellent synopsis of the development of the theory of the calculus of variations with elaborate references see two articles by A. Kneser; and by E. Zermelo and H. Hahn, *Encyklopädie der Mathematischen Wissenschaften*, II. A 8 (1900), II. A. 8a (1904). These have been translated into French and amplified importantly by Maurice Lécat *Encyclopédie des Sciences Mathématiques*, II. 31 (1913, 1916), pp. 1–288.

Books dealing with the history of the subject are M. Cantor, *Geschichte der Mathematik*, vols. i–iv. (Teubner, Leipzig, 1892–1908); and I. Todhunter, *A History of the Progress of the Calculus of Variations during the Nineteenth Century* (Macmillan, 1861), treating the period from 1760 to 1860. An interesting historical sketch is contained in Pascal, *Calcolo delle Variazioni* (Hoepli, 1897), which has also been translated into German by Adolf Schepp (*Die Variationsrechnung* (Teubner, Leipzig, 1899)).

An extensive bibliography has been published by M. Lécat, *Bibliographie du Calcul des Variations, depuis les origines jusqu'à 1850* (Hermann, 1916); 1850–1913 (ditto, 1913). See also the additions in his *Bibliographie des Séries Trigonométriques* (M. Lécat, 1921), p. 155; and in his *Bibliographie de la Relativité* (M. Lamartin, 1924), Appendix, p. 15. A brief bibliography of the principal treatises is given by G. A. Bliss in the book mentioned above. Two new books whose names do not appear there are G. Vivanti, *Elementi del Calcolo delle Variazioni* (Principato, Messina, 1923); and A. R. Forsyth, *Calculus of Variations* (Cambridge University Press, 1927). (G. A. Bl.)

**CALCUTTA**, a city in British India and the capital of the province of Bengal. It is situated in  $22^{\circ} 34' N.$  and  $88^{\circ} 24' E.$ , on the left or east bank of the Hugli, about 80m. from the sea. It extends over an area of 32 sq.m. and contains a population (1921) of 1,132,246. Including Howrah on the other side of the river, which has been described as being as much a part of Calcutta as Southwark is of London, Calcutta has a total population

THE BADRI DAS TEMPLE, THE CENTRE OF THE JAIN SYSTEM IN CALCUTTA

of 1,327,547 and claims to be the second city in the British empire. It was until 1912 the seat of the Government of India, which in that year was transferred to Delhi.

**Buildings.**—Though Calcutta has been called “the city of palaces,” its modern public buildings cannot compare with those of Bombay. Its chief glory is the *Maidan* or park, 2 sq.m. in area, which is large enough to embrace the area of Ft. William and a racecourse. It is adorned by many statues and a pillar 165ft. high erected to the memory of Sir David Ochterlony, who brought the Nepalese War to a victorious conclusion. South-east of the Maidan stands the finest building in Calcutta, the Victoria Memorial, the conception of which was due to Lord Curzon; it was built on the site of the old gaol and opened in 1921. It is a domed marble building with a great centre dome, and contains pictures, documents, etc., illustrating Indian history. This great building dwarfs the cathedral, to the east of it, which has a spire 207ft. high. A war memorial to the lascars of Bengal and Assam has been erected near Prinsep's Ghat by the river bank. Government House, which is situated near the Maidan and Eden gardens, was the residence of the viceroy until 1912, since when it has been occupied by the governor of Bengal. It was built by Lord Wellesley in 1799, and is a fine pile situated in grounds covering six acres. The town hall has been used for some years for meetings of the Bengal legislature pending the construction of a separate council chamber. The High Court building in its vicinity was designed on the model of the town hall at Ypres. Calcutta being a city of modern growth, there are few buildings of any considerable age. Lord Curzon restored, at his own cost, the monument which formerly commemorated the massacre of the Black Hole, and a tablet let into the wall of the general post office indicates the position of the Black Hole in the north-east bastion of Ft. William, now occupied by the roadway. Belvedere House, a country house of Warren Hastings and the official residence of the lieutenant-governor of Bengal from 1854 to 1921 is situated close to the zoological gardens in Alipore, the southern suburb of Calcutta. Here also are Hastings House, another residence of Warren Hastings, the Bengal Meteorological Observatory and cantonments. Facing the Maidan for a couple of miles is

Chowringhee, once a row of palatial residences, but now given up almost entirely to hotels, clubs and shops. Several magnificent buildings have been erected in the commercial quarter, including the Royal Exchange. Some areas have been almost transformed by an improvement trust which since its creation in 1912 has carried out the clearing of insanitary areas; the widening and construction of roads (the chief being the Central avenue, a fine road roofed wide running north and south through the heart of the city); the provision of model dwellings for families dispossessed under its schemes; and the laying out of suburban land for private building.

**Commerce.**—Calcutta owes its commercial prosperity to the fact that it is the natural port of north-east India, on which ocean, river and rail traffic converge. It receives the produce of the fertile river valleys of the Ganges and Brahmaputra, and being situated midway between Europe and the Far East it forms a meeting-place for the commerce of the eastern and western worlds. The port is one of the busiest in the world, and the banks of the Hooghly rival the port of London in their show of shipping. The port of Calcutta is under the control of a port trust, whose jurisdiction extends to the mouth of the Hooghly. Vessels of 10,000 tons drawing 28ft. and more ascend this great river to Calcutta; it is a dangerous river owing to mud shoals constantly forming, but is kept safe for navigation by the efforts of the port trust and the skill of the pilots. The river is also connected with eastern Bengal and Assam by a series of natural waterways and of navigable channels (some artificial) with a total length of 1,100 miles. The tonnage of vessels entering the port in 1926-27 exceeded four millions. Howrah is the terminus of two great railway systems, and is linked with Calcutta by an immense floating bridge, 1,530ft. in length, which was constructed in 1874. It was decided in 1924 to build a cantilever bridge over the river. A third large railway has its terminus at Sealdah, an eastern suburb. Docks were opened at Kidderpore to the south in 1892. Owing to the increased trade, it has been found necessary to build a new dock (King George's dock) below them. Work on the main scheme was begun in 1920 and is in progress.

**Municipality.**—The Municipal Government of Calcutta is regulated by acts of the Bengal legislature, passed in 1899 and 1923. Female suffrage was introduced by the act of 1923. The corporation consists of 85 councillors, with a mayor, deputy-mayor and aldermen elected by the council. The water-supply is derived from the river Hooghly about 16m. above Calcutta; an iron reservoir, said to be the second largest in the world, has been erected at Talia to the north of the city. The drainage system consists of underground sewers, which are discharged into a natural depression to the eastward, called the Salt lake.

**The University of Calcutta.**—The University of Calcutta was founded, together with those of Madras and Bombay, by an Indian act in 1857, on the model of the University of London. After the report from Lord Curzon's universities' commission in 1902 it was given teaching powers by an act in 1904; and the university is still working entirely under the acts above named save for the substitution by an act of 1921 of the governor of Bengal for the governor-general as chancellor, and of the local government for the governor-general in council, as the determining authority for a number of university matters.

The university exercises control over the hundreds of secondary schools in Bengal by means of the matriculation examination, for which from 16,000 to 19,000 candidates present themselves annually; it exercises control over the "affiliated" colleges by determining the curricula and examinations in the faculties of arts, laws, teaching (education), science, medicine and engineering; and it carries on since 1909 "post-graduate" teaching in arts and science and teaching in law in the university law college. A comprehensive survey of the university work was made by the Calcutta university commission presided over by Dr. (now Sir) Michael Sadler in 1917-19. Since the report was issued an area with a radius of five miles in the Dacca district and the province of Burma have been removed from the educational jurisdiction of Calcutta and the universities of Dacca (*q.v.*) and Rangoon created in 1921. In 1928 the senate adopted a resolution approv-

ing reorganization on the lines of this report. There are a number of affiliated institutions, of which the chief is Presidency college, maintained by Government. The university has a number of endowed chairs and lectureships and a very large number of benefactions for scholarships and prizes.

**Population.**—The population has been nearly doubled in the last half century. It is a mixture of many races and presents curious anomalies. Though a creation of British rule, Calcutta contains only 13,000 Europeans; though the capital of Bengal, only 53% of its inhabitants are Bengalis; though it is the seat of a university and the provincial centre of education, less than half can read and write.

Hardly more than one-third of its population were born in Calcutta; men outnumber women by two to one, the bulk being below the age of forty. The explanation of these peculiarities is that the trade and manufactures of the city attract an enormous number of able-bodied men, mostly illiterate workers, from outside. The day population largely exceeds that which sleeps in the city; there are 300,000 season ticket holders to the railway termini. As in other towns in Bengal, Hindus predominate, outnumbering Mohammedans by 480,000.

**Climate.**—The condition of the city was formerly very unhealthy, but it has improved greatly of recent years with modern sanitation and drainage, and it is now as healthy a place as any in the plains of Bengal. The climate is hot and damp; the quantity of vapour in the air is more than twice as great as it is in that of London. Calcutta has a pleasant cold season from the end of November to March; April, May and June are hot; and the monsoon months from June to October are distinguished by heat and humidity. The mean annual temperature is 79° F, with a range from 85° in the hot season and 83° in the rains to 72° in the cool season, a mean maximum of 102° in May and a mean minimum of 48° in January.

## HISTORY

The history of Calcutta practically dates from Aug. 24, 1690, when it was founded by Job Charnock (*q.v.*) of the English East India Company. In 1596 it had obtained a brief entry as a rent-paying village in the survey of Bengal executed by command of the Emperor Akbar. In 1686 the English merchants at Hugli retreated about 26m. down the river to Sutanati, a village now within the boundaries of Calcutta. They occupied Sutanati temporarily in Dec. 1686, and permanently on Aug. 24, 1690. The new settlement soon extended itself along the river bank to the then village of Kalikata, and by degrees the cluster of neighbouring hamlets grew into the present town. In 1696 the English built the original Fort William by permission of the nawab, and in 1698 they formally purchased the three villages of Sutanati, Kalikata and Govindpur from Prince Azim, son of the Emperor Aurangzeb.

The site thus chosen had an excellent anchorage and was defended by the river from the Mahrattas, who harried the districts on the other side. The fort, subsequently rebuilt on the Vauban principle, combined with the natural position of Calcutta to render it one of the safest places for trade in India during the expiring struggles of the Mogul empire. It grew up without any fixed plan and with little regard to the sanitary arrangements required for a town. Some parts of it lay below high-water mark on the Hugli, and its low level throughout rendered its drainage a most difficult problem.

The chief event in the history of Calcutta is the sack of the town, and the capture of Fort William in 1756, by Suraj-ud-Dowlah, the nawab of Bengal. The majority of the English officials took ship and fled to the mouth of the Hugli river. The Europeans who remained were compelled, after a short resistance, to surrender. The prisoners, numbering 146 persons, were forced into the guard-room, a chamber measuring only 18ft. by 14ft. 10in., with but two small windows, where they were left for the night. It was the 20th of June; the heat was intense; and next morning only 23 were taken out alive, among them Holwell, who left an account of the awful sufferings endured in the "Black Hole." The site of the Black Hole is now covered with a black

marble slab, and the incident is commemorated by a monument erected by Lord Curzon in 1902. In Jan. 1757 the expedition despatched from Madras, under the command of Admiral Watson and Colonel Clive, regained possession of the city. The battle of Plassey was fought on June 23, 1757, exactly 12 months after the capture of Calcutta. Mir Jafar, the nominee of the English, was created nawab of Bengal, and by the treaty which raised him to this position he agreed to make restitution to the Calcutta merchants for their losses. By another clause in this treaty the Company was permitted to establish a mint, the visible sign in India of territorial sovereignty, and the first coin, still bearing the name of the Delhi emperor, was issued on August 19, 1757. Modern Calcutta dates from 1757. The old fort was abandoned, and its site devoted to the custom-house and other Government offices. A new fort, the present Fort William, was begun by Clive a short distance lower down the river. At this time also the *maidan*, the park of Calcutta, was formed.

Up to 1707, when Calcutta was first declared a presidency, it had been dependent upon the older English settlement at Madras. From 1707 to 1773 the presidencies were maintained on a footing of equality; but in the latter year the act of parliament was passed, which provided that the presidency of Bengal should exercise a control over the other possessions of the Company; that the chief of that presidency should be styled governor general; and that a supreme court of judicature should be established at Calcutta. In the previous year, 1772, Warren Hastings had taken, under the immediate management of the Company's servants, the general administration of Bengal. The treasury was removed from Murshidabad to Calcutta which thus became the capital. In 1834 the governor general of Bengal was created governor general of India. It was not until 1854 that a separate head was appointed for Bengal. In 1912 the 1905 partition of Bengal was reversed and Calcutta was no longer the capital of India, the seat of Government being transferred to Delhi (*q.v.*). Since 1920 the harbour has been greatly extended and in internal development and foreign trade, Calcutta still leads the other large cities of Northern India. (See *BENGAL*.)

See A. K. Ray, *A Short History of Calcutta* (Indian Census, 1901); C. R. Wilson, *Early Annals of the English in Bengal* (1895); and *Old Fort William in Bengal* (1906); S. S. O'Malley, *History of Bengal, Bihar and Orissa under British Rule*, Calcutta (1925).

**CALDECOTT, RANDOLPH** (1846–1886), English artist and illustrator, was born at Chester on March 22, 1846, and died in Florida on Feb. 12, 1886. He was a prolific and original illustrator, gifted with a genial humorous faculty, and he succeeded also, though in less degree, as a painter and sculptor.

His most famous book illustrations are those for:—*Old Christmas* (1876) and *Bracebridge Hall* (1877), both by Washington Irving; *North Italian Folk* (1877), by Mrs. Comyns Carr; *The Harz Mountains* (1883); *Breton Folk* (1879), by Henry Blackburn; picture-books (*John Gipsy*, *The House that Jack Built*, and other children's favourites) from 1878 onwards; *Some Aesop's Fables with Modern Instances*, etc. (1883). He held a roving commission for the *Graphic*, and was an occasional contributor to *Punch*. He was a member of the Royal Institute of Painters in Water-colours. See Henry Blackburn, *Randolph Caldecott, Personal Memoir of his Early Life* (1886).

**CALDER, SIR ROBERT, BART.** (1745–1818), British admiral, was born at Elgin, in Scotland, on July 2, 1745 (o.s.), of an old family, and at the age of 14 entered the British navy as midshipman. In 1796 he was named captain of the fleet by Sir John Jervis, and took part in the great battle off Cape St. Vincent (Feb. 14, 1797). He received a baronetcy in 1798. In 1799 he became rear-admiral; and in 1801 he was despatched with a small squadron in pursuit of a French force, under Admiral Gantheaume, conveying supplies to the French in Egypt. In this pursuit he was not successful, and returning home at the peace he struck his flag. When the war again broke out he was recalled to service, was promoted vice-admiral in 1804, and was employed in the following year in the blockade of the ports of Ferrol and Corunna, in which (amongst other ports) ships were preparing for the invasion of England by Napoleon I. He held his position with a force greatly inferior to that of the enemy, and refused to be enticed out to sea. On its becoming known that the first movement directed by Napoleon was the raising of the blockade of

Ferrol, Rear-Admiral Stirling was ordered to join Sir R. Calder and cruise with him to intercept the fleets of France and Spain on their passage to Brest. The approach of the enemy was concealed by a fog; but on July 22, 1805, their fleet came in sight. It still outnumbered the British force; but Sir Robert entered into action. After a combat of four hours, during which he captured two Spanish ships, he gave orders to discontinue the action. He offered battle again on the two following days, but the challenge was not accepted. The French admiral Villeneuve, however, did not pursue his voyage, but took refuge in Ferrol. In the judgment of Napoleon, his scheme of invasion was baffled by this day's action; but much indignation was felt in England at the failure of Calder to win a complete victory. In consequence of the strong feeling against him at home he demanded a court-martial. This was held on Dec. 23, and resulted in a severe reprimand of the vice-admiral for not having done his utmost to renew the engagement, at the same time acquitting him of both cowardice and disaffection. False expectations had been raised in England by the mutilation of his despatches, and of this he indignantly complained in his defence. The tide of feeling, however, turned again; and in 1815, by way of public testimony to his services, and of acquittal of the charge made against him, he was appointed commander of Portsmouth. He died at Holt, near Bishop's Waltham, Hampshire, on Aug. 31, 1818.

See *Naval Chronicle*, xvii.; James, *Naval History*, iii. 356–379 (1860).

**CALDER**, an ancient district of Midlothian, Scotland. It is divided into the parishes of Mid-Calder (pop. 1931, 2,793) and West Calder (pop. 6,817), East Calder belonging to the parish of Kirknewton. The locality owes some of its commercial importance to the mineral oil industry, which, however, has now declined. Coal is mined, sandstone and limestone are worked, and paper is made. Mid-Calder, a town on the Almond, has an ancient church, and John Spottiswood (1510–1585), the Scottish reformer, was for many years minister. The town of West Calder (pop. 3,949), within the parish of that name, is situated on Breich Water, an affluent of the Almond, 1½ m. S.W. of Edinburgh by the L.M.S.R., and is the chief centre of the district. At Addiewell, about 1½ m. S.W., the manufacture of ammonia, naphtha, paraffin oil and candles is carried on; the village dates from 1866, and had in 1921 a population of 3,141. Oil is also refined at Pumpherston. The district contains several tumuli, old ruined castles and a Roman camp which is in a state of comparatively good preservation.

**CALDERON, GEORGE** (1868–1915), British dramatist, was born in London on Dec. 2, 1868, the son of the painter Philip H. Calderon, R.A. Educated at Rugby and Trinity college, Oxford, he spent two years in St. Petersburg (Leningrad) (1895–97), and from that time onwards took a deep interest in Russian literature and in the dialects and folk-lore of the Slav peoples generally. He was for a short time an official of the British Museum. His first play, *The Fountain*, was produced by the Stage Society in 1909. His collected plays were posthumously printed in 1921–22; they included a tragedy in blank verse entitled *Cromwell: Mall o' Monks*. He wrote one volume of impressions of travel, *Tahiti*, after a visit to the South Seas in 1906. In the World War Calderon served first as an interpreter in France and then as a line officer in the Dardanelles. His name was in the wounded and missing list of June 4, 1915.

**CALDERON, PHILIP HERMOGENES** (1833–1898), English painter, born at Poitiers, only son of the Rev. Juan Calderon, a native of La Mancha. He was educated from his 12th year in London, where his father was professor of Spanish literature at King's college. He began his artistic studies in 1850 at Leigh's, in Newman street. When nearly 20 he went to Paris to study at the École des Beaux-Arts, under M. Picot. His most popular picture is "Broken Vows," exhibited at the Royal Academy in 1857. He became A.R.A. in 1864, R.A. in 1867. He was elected keeper of the Royal Academy in 1887, and died at Burlington House on April 30, 1898. Calderon belonged to the so-called St. John's Wood school, which excelled in genre pictures with historical interest.

**CALDERÓN, RODRIGO** (d. 1621), COUNT OF OLIVA AND MARQUESS DE LAS SIETE INGLSIAS, Spanish favourite and adventurer, was born at Antwerp, the son of a Spanish army officer. In 1598 he entered the service of the duke of Lerma as secretary. He was created count of Oliva, a knight of Santiago, commendador of Ocaña in the order, secretary to Philip III. and made an advantageous marriage with Ines de Vargas. As an insolent upstart he was peculiarly odious to the enemies of Lerma. Two religious persons, Juan de Santá Maria, a Franciscan, and Mariana de San José, prioress of La Encarnacion, worked on the queen Margarita, by whose influence Calderón was removed from the secretaryship in 1611. But he retained the favour of Lerma, and in 1612 he was sent on a special mission to Flanders, and on his return was made marqués de Las Siete Inglesias in 1614. When queen Margarita died in that year in childbirth Calderón was accused of having used witchcraft against her. Soon after, it became generally known that he had ordered the murder of one Francisco de Juaras. On Lerma's disgrace in 1618 he was arrested, despoiled, and on Jan. 7, 1620, was savagely tortured until he confessed to the murder of Juaras, although he steadfastly denied all the other charges. He met his fate firmly with a show of piety on Oct. 21, 1621. Lord Lytton made Rodrigo Calderón the hero of his story *Calderón the Courtier*.

See Modeste de la Fuente, *Historia General España*, vol. xv. pp. 452 et seq. (1850-67); Quevedo, *Obras*, vol. x.—*Grandes Anales de Quince Dias* (1794). A curious contemporary French pamphlet on Calderón, *Histoire admirable et déclin pitoyable advenue en la personne d'un favori de la Cour d'Espagne*, is reprinted by M. E. Fournier in *Variétés historiques*, vol. i. (1855).

**CALDERÓN DE LA BARCA, PEDRO** (1600-1681), Spanish dramatist and poet, was born at Madrid on Jan. 17, 1600. He was educated at the Jesuit college in Madrid with a view to accepting a family living; abandoning this project, he studied law at Salamanca, and competed with success at the literary fêtes held in honour of St. Isidore at Madrid (1620-22). From 1625-35 Calderón seems to have resided at Madrid. Early in 1629 his brother Diego was stabbed by an actor, who took sanctuary in the convent of the Trinitarian nuns; Calderón and his friends broke into the cloister and attempted to seize the offender. This violation was denounced by the fashionable preacher, Hortensio Félix Paravicino (*q.v.*), in a sermon preached before Philip IV.; Calderón retorted by introducing into *El príncipe constante* a mocking reference (afterwards cancelled) to Paravicino's gongoristic verbiage, and was committed to prison. He was soon released, grew rapidly in reputation as a playwright, and, on the death of Lope de Vega in 1635, was recognized as the foremost Spanish dramatist of the age. A volume of his plays, edited by his brother José in 1636, contains such celebrated and diverse productions as *La Vida es sueño*, *El Purgatorio de San Patricio*, *La Devoción de la cruz*, *La Dama duende* and *Peor está que estaba*. In 1636-37 he was made a knight of the order of Santiago by Philip IV., who had already commissioned from him a series of spectacular plays for the royal theatre in the Buen Retiro. Calderón was almost as popular with the general public as Lope de Vega had been in his zenith; he was, moreover, in high favour at court, but this royal patronage did not help to develop the finer elements of his genius. On May 28, 1640, he joined a company of mounted cuirassiers raised by Olivares, took part in the Catalan campaign, and distinguished himself by his gallantry at Tarragona; his health failing, he retired from the army in Nov. 1642, and three years later was awarded a special military pension in recognition of his services in the field. The history of his life during the next few years is obscure. He appears to have been profoundly affected by the death of his mistress—the mother of his son Pedro José—about the year 1648-49; his long connection with the theatre had led him into temptations, but it had not diminished his instinctive spirit of devotion, and he now sought consolation in religion. He became a tertiary of the order of St. Francis in 1650, and finally reverted to his original intention of joining the priesthood. He was ordained in 1651, was presented to a living in the parish of San Salvador at Madrid, and, according to his statement made a year or two later, determined to give up writing for the stage. He did not adhere

to this resolution after his preferment to a prebend at Toledo in 1653, though he confined himself as much as possible to the composition of *autos sacramentales*—allegorical pieces in which the mystery of the Eucharist was illustrated dramatically, and which were performed with great pomp on the feast of Corpus Christi and during the weeks immediately ensuing. In 1662 two of Calderón's *autos*—*Las órdenes militares* and *Mística y real Babilonia*—were the subjects of an enquiry by the Inquisition; the former was censured; the manuscript copies were confiscated, and the condemnation was not rescinded till 1671. Calderón was appointed honorary chaplain to Philip IV. in 1663, and the royal favour was continued to him in the next reign. In his 81st year he wrote his last secular play, *Hado y Divisa de Leonido y Marfisa*, in honour of Charles II.'s marriage to Marie-Louise de Bourbon. Notwithstanding his position at court and his universal popularity throughout Spain, his closing years seem to have been passed in poverty. He died on May 25, 1681.

Like most Spanish dramatists, Calderón wrote too much and too speedily, and he was too often content to recast the productions of his predecessors. His *Saber del mal y del bien* is an adaptation of Lope de Vega's play, *Las Mudanzas de la fortuna y sucesos de Don Beltrán de Aragón*; his *Selva confusa* is also adapted from a play of Lope's which bears the same title; his *Encanto sin encanto* derives from Tirso de Molina's *Amar por señas*, and, to take an extreme instance, the second act of his *Cabellos de Absalón* is transferred almost bodily from the third act of Tirso's *Venganza de Tamar*. It would be easy to add other examples of Calderón's lax methods, but it is simple justice to point out that he committed no offence against the prevailing code of literary morality. Many of his contemporaries plagiarized with equal audacity, but with far less success. Sometimes, as in *El Alcalde de Zalamea*, the bold procedure is completely justified by the result; in this case by his individual treatment he transforms one of Lope de Vega's rapid improvisations into a finished masterpiece. It was not given to him to initiate a great dramatic movement; he came at the end of a literary revolution, was compelled to accept the conventions which Lope de Vega had imposed on the Spanish stage, and he accepted them all the more readily since they were peculiarly suitable to the display of his splendid and varied gifts. Not a master of observation or an expert in invention, he showed an unexampled skill in contriving ingenious variants on existing themes; he had a keen dramatic sense, an unrivalled dexterity in manipulating the mechanical resources of the stage, and in addition to these minor indispensable talents he was endowed with a lofty philosophic imagination and a wealth of poetic diction. Naturally, he had the defects of his great qualities; his ingenuity is apt to degenerate into futile embellishment; his employment of theatrical devices is the subject of his own good-humoured satire in *No hay burlas con el amor*; his philosophic intellect is more interested in theological mysteries than in human passions; and the delicate beauty of his style is tinged with a wilful preciousness. Excelling Lope de Vega at many points, Calderón falls below his great predecessor in the delineation of character. Yet in almost every department of dramatic art Calderón has obtained a series of triumphs. In the symbolic drama he is best represented by *El Príncipe constante*, by *El Mágico prodigioso* (familiar to English readers in Shelley's free translation), and by *La Vida es sueño*, perhaps the most profound and original of his works. His tragedies are more remarkable for their acting qualities than for their convincing truth, and the fact that in *La Niña de Gomez Arias* he interpolates an entire act borrowed from Velez de Guevara's play of the same title seems to indicate that this kind of composition awakened no great interest in him; but in *El Médico de su honra* and *El Mayor monstruo los celos* the theme of jealousy is handled with sombre power, while *El Alcalde de Zalamea* is one of the greatest tragedies in Spanish literature. Calderón is seen to much less advantage in the spectacular plays—*dramas de tramoya*—which he wrote at the command of Philip IV.; the dramatist is subordinated to the stage-carpenter, but the graceful fancy of the poet preserves even such a mediocre piece as *Los Tres Mayores prodigios* (which won him his knighthood) from complete oblivion. A greater opportunity is afforded in the more animated *comedias palaciegas*, or melodramatic pieces

destined to be played before courtly audiences in the royal palace: *La Banda y la flor* and *El Galán fantasma* are charming illustrations of Calderón's genial conception and refined artistry. His historical plays (*La Gran Cenobia*, *Las armas de la hermosura*, etc.) are the weakest of all his formal dramatic productions; *El Golfo de las sirenas* and *La Púrpura de la rosa* are typical *zarzuelas*, to be judged by the standard of operatic libretti; and the *entremeses* are lacking in the lively humour which should characterize these dramatic interludes. On the other hand, Calderón's faculty of ingenious stagecraft is seen at its best in his "cloak-and-sword" plays (*comedias de capa y espada*), which are invaluable pictures of contemporary society. They are conventional, no doubt, in the sense that all representations of a specially artificial society must be conventional; but they are true to life and are still as interesting as when they first appeared. In this kind *No siempre lo peor es cierto*, *La Dama duende*, *Una casa con dos puertas mala es de guardar* and *Guárdate del agua mansa* are almost unsurpassed. But it is as a writer of *autos sacramentales* that Calderón defies rivalry; his intense devotion, his subtle intelligence, his sublime lyricism, all combine to produce such marvels of allegorical poetry as *La Cena del rey Baltasar*, *La Viña del Señor* and *La Serpiente de metal*. The *autos* lingered on in Spain till 1765, but they may be said to have died with Calderón, for his successors merely imitated him with a tedious fidelity. Almost alone among Spanish poets, Calderón had the good fortune to be printed in a fairly correct and readable edition (1682-91), thanks to the enlightened zeal of his admirer, Juan de Vera Tassis y Villaroel, and owing to this happy accident he came to be regarded generally as the first of Spanish dramatists. The publication of the plays of Lope de Vega and of Tirso de Molina has affected the critical estimate of Calderón's work; he is seen to be inferior to Lope de Vega in creative power, and inferior to Tirso de Molina in variety of conception. But, setting aside the extravagances of his admirers, he is admittedly an exquisite poet, an expert in the dramatic form, and a typical representative of the devout, chivalrous, patriotic, and artificial society in which he moved. (J. F.-K.)

**BIBLIOGRAPHY.**—H. Breymann, *Calderon-Studien* (1905), i. Teil, contains a fairly exhaustive list of editions, translations and arrangements; *Autos sacramentales* (1759-60), ed. J. Fernandez de Apontes; *Comedias* (1848-50), ed. J. E. Hartzenbusch; *Teatro selecto* (1884) ed. M. Menéndez y Pelayo; *El Mágico prodigioso* (Heilbronn, 1877), ed. A. Morel-Fatio; *Select Plays of Calderón* (1888), ed. N. MacColl. See also E. Fitzgerald, *Six Dramas of Calderón* (1853), a free translation; F. W. V. Schmidt, *Die Schauspiele Calderón's* (Elberfeld, 1857); M. Menéndez y Pelayo, *Calderón y su teatro* (1881); E. Günthner, *Calderon und seine Werke* (Freiburg i. B. 1888); C. Pérez Pastor, *Documentos para la biografía de D. Pedro Calderón de la Barca* (1905); S. de Madariaga, *Shelley and Calderón* (1920).

**CALDERWOOD, DAVID** (1575-1650), Scottish divine and historian, was educated at Edinburgh, where he took the degree of M.A. in 1593. About 1604 he became minister of Crailing, near Jedburgh, and resolutely opposed the introduction of Episcopacy. In 1617, while James was in Scotland, a Remonstrance, which had been drawn up by the Presbyterian clergy, was placed in Calderwood's hands. He was summoned to St. Andrews and examined before the king, but neither threats nor promises could make him deliver up the roll of signatures to the Remonstrance. The privy council ordered him to be banished from the kingdom for refusing to acknowledge the sentence of the High Commission. On Aug. 27, 1619, he sailed for Holland. During his residence in Holland he published his *Altare Damascenum* (1623). Calderwood appears to have returned to Scotland in 1624, and he was soon afterwards appointed minister of Pencaitland, in the county of Haddington. His last years were devoted to the preparation of a *History of the Kirk of Scotland*, the ms. of which is in the British Museum. An abridgment was published in 1678. A digest of the complete work was published by the Wodrow Society (1842-49). Calderwood died at Jedburgh on Oct. 25, 1650.

**CALDERWOOD, HENRY** (1830-1897), Scottish philosopher and divine, was born at Peebles on May 10, 1830. He was educated at the Royal High school and the University of Edinburgh. In 1856 he was ordained pastor of the Greyfriars church, Glasgow. He taught moral philosophy at Glasgow university until,

in 1868, he became professor of moral philosophy at Edinburgh. He was made LL.D. of Glasgow in 1865. He died on Nov. 19, 1897. His first and most famous work was *The Philosophy of the Infinite* (1854) in which he attacked the statement of Sir William Hamilton that we can have no knowledge of the Infinite. Calderwood held that such knowledge can exist; that Faith implies knowledge. His moral philosophy endeavours to substantiate the doctrine of divine sanction. Beside the data of experience, the mind has pure activity of its own whereby it apprehends reality. He wrote in addition *A Handbook of Moral Philosophy* (1872); *On the Relations of Mind and Brain* (1879); *Science and Religion* (1880); *Evolution and Man's place in Nature* (1893). Among his religious works the best known is his *Parables of Our Lord* (1880), and just before his death he finished a *Life of David Hume* in the "Famous Scots" series (1896). He was the first chairman of the Edinburgh school board.

**CALDWELL**, a city of Idaho, U.S.A., in the fertile Boise valley, near the western boundary of the State; the county seat of Canyon county. It is on Federal highway 30 and the Oregon Short Line of the Union Pacific railway system. The population in 1930 was 4,974. It is the centre of a government irrigation project of 144,200 ac., 80% of which is already under crops. The College of Idaho was established here in 1890.

**CALDWELL**, a town of Essex County, New Jersey, named in honour of a hero of the Revolution; population in 1930 was 5,144; connected by the Erie Railway and motor bus with neighbouring cities. Here Grover Cleveland, twice President of the United States, was born on March 18, 1837; Cleveland Park was named in his honour.

**CALEB**, in the Bible, one of the spies sent by Moses from Kadesh in South Palestine to spy out the land of Canaan. For his courage he was rewarded by the promise that he and his seed should possess it (Num. xiii. seq.). Later tradition includes Joshua, the hero of the conquest of the land. Subsequently Caleb settled in Kirjath-Arba (Hebron), but there are different accounts. (a) Caleb drove out the Anakites, giants of Hebron, and gave his daughter Achsah to Othniel, his brother, who took Kirjath-Sepher or Debir (Jos. xv. 14-19). Both are "sons" of Kenaz, an Edomite clan (Gen. xxxvi). Elsewhere (b) Caleb the Kenizzite reminds Joshua of the promise at Kadesh; he asks that he may have the "mountain whereof Yahweh speaks," and hopes to drive out the giants from its midst. Joshua blesses him and thus Hebron becomes the inheritance of Caleb (Josh. xiv. 6-15). Further (c) the capture of Hebron and Debir is ascribed to Judah who gives them to Caleb (Judg. i. 10 seq. 20); and finally (d) these cities are taken by Joshua himself in the course of a great campaign against South Canaan (Josh. x. 36-39). The seat of the clan was at Carmel in South Judah, and Abigail, the wife of the Calebite Nabal, was taken by David after her husband's death (I Sam. xxv., xxx. 14). Later the small divisions of the south were united under the name Judah, and this is reflected in the genealogies of I Chron. ii., iv., where Caleb and Jerahmeel become descendants of JUDAH (q.v.).

**CALEDON**, a town 87 m. from Cape Town, situated 34° 14' S., 19° 25' E., on a spur of the Zwartberg, at an altitude of 754 feet. Pop. 1,498 whites and about 1,000 coloured. It is not laid out in the usual rectangular plan. The streets conform to the irregularities of the slopes, and are lined with oaks and blue gums. The town has several mineral springs, of which six have a temperature of 118°. It used to be visited by Dutch and British officials from the East Indies and India, who are said to have derived much benefit from the baths, which are radioactive. The opening of the Suez canal diverted this traffic, but in recent years Caledon has attracted more health-seeking visitors. Sixteen baths and a hot swimming-bath have been installed.

The district of Caledon is largely devoted to pastoralism. Wool and grain are its chief products. It also has a large trade in wild flowers, especially everlastings, and many varieties of heaths. Good shooting is to be had. Caledon is also the name of a tributary of the Orange River (q.v.).

**CALEDONIA**, the Roman name of North Britain, still used for Scotland, especially in poetry. It occurs first in the poet

Lucan (A.D. 64), and then often in Roman literature. There were (1) a district Caledonia, of which the southern border must have been on or near the isthmus between the Clyde and the Forth, (2) a Caledonian Forest (possibly in Perthshire), and (3) a tribe of Caledones or Calidones, named by the geographer Ptolemy as living within boundaries which are now unascertainable. The Romans first invaded Caledonia under Agricola about A.D. 82. After a brief halt on the Forth and Clyde Isthmus, where they established a line of temporary posts, one or two of which, notably that at Barhill, have been identified through excavation, they penetrated farther north and fought the decisive battle of the war, according to Tacitus on the slopes of Mons Graupius. (This, not Grampius, is the proper spelling, though Grampius was at one time commonly accepted and indeed gave rise to the modern name Grampian.) The site must have been some way beyond the Roman encampment of Inchtuthill (in the policies of Delvine, 10 m. north of Perth near the union of Tay and Isla), which is the most northerly of the ascertained Roman encampments of a permanent character in Scotland and belongs to the age of Agricola. Tacitus represents the result as a victory. The home government, whether averse to expensive conquests of barren hills, or afraid of a victorious general, abruptly recalled Agricola. The old view that his northern conquests were abandoned is not borne out by the results of recent research. Rather, there is evidence to show that they were held for 20 or 30 years after his departure, though not without various vicissitudes. The abundance and richness of the relics found at Newstead, the Trimontium of Ptolemy, suggests that, on one occasion at least, the withdrawal was anything but orderly. Finally Hadrian fixed the frontier to the south of Cheviot. The next advance followed immediately. About A.D. 142, when the district up to the Firth of Forth was definitely annexed, and a rampart with forts along it, the Wall of Antoninus Pius, was drawn from sea to sea (see BRITAIN: Roman; and ANTONINUS PIUS). At the same time a few other forts such as Ardoch, north of Dunblane and Carpow near Abernethy were occupied or reoccupied. But the conquest was stubbornly disputed, and after several risings, the land north of Cheviot was lost about A.D. 180-185. About A.D. 208 the emperor Septimius Severus carried out an extensive punitive expedition against the northern tribes. It is doubtful how far he penetrated, for he has left no indubitable traces of his presence save at Cramond on the Forth, and the great temporary camps that have been recognized in the shires of Forfar, Kincardine and Aberdeen, may as easily belong to earlier campaigns as to his. It is, however, clear that after his death the Roman writ never again ran north of Cheviot. Rome, indeed, is sometimes said to have recovered the whole land up to the Wall of Pius in A.D. 368 and to have established there a province, Valentia. A province with that name was certainly organized somewhere. But its site and extent are quite uncertain and its duration was exceedingly brief. Throughout, Scotland remained substantially untouched by Roman influences, and its Celtic art, though perhaps influenced by Irish, remained free from Mediterranean infusion. Even in the south of Scotland which was for a time within the empire, the occupation was military and produced little civilizing effect. Of the actual condition of the land during the period of Roman rule in Britain, we are only beginning to learn the details by excavation. The remains from the purely native settlement on Traprain Law in East Lothian, where the houses were of daub and wattle, include much Roman pottery and many Roman coins. The "brochs," the "crannogs," and the underground stone houses locally called "weems" in all three of which Roman fragments have been found, were also native forms of dwelling, etc., and some of the "Late Celtic" metal work may belong to this age. But of the political divisions, the boundaries and capitals of the tribes, and the like, we know nothing. Ptolemy gives a list of tribes and place names. But hardly one can be identified with any approach to certainty, except in the extreme south. Nor has unanimity quite been reached about the ethnological problems of the population, the Aryan or non-Aryan character of the Picts and the like. The name Caledonia is said to survive in the second syllable of Dunkeld and in "Schiehallion" (Sithchailinn).

**CALEDONIAN CANAL.** The chain of fresh-water lakes—Lochs Ness, Oich and Lochy—which stretch along the line of the Great Glen of Scotland in a south-west direction from Inverness, early suggested the idea of connecting the east and west coasts of Scotland by a canal which would save ships about 400 m. of coasting voyage round the north of Great Britain through the stormy Pentland firth. In 1773 James Watt was employed by the government to make a survey for such a canal, which was constructed by Thomas Telford and opened in 1822. From the northern entrance on Beaully firth to the southern, near Ft. William, the total length is about 60 m., that of the artificial portion being about 22 m. The number of locks is 28, and their lift is in general about 8 ft., but some of them are for regulating purposes only. The navigation is vested in and managed by the commissioners of the Caledonian canal, of whom the speaker of the House of Commons is *ex officio* chairman. Any profits must be expended on renewals and improvements of the canal, but parliament is occasionally called upon to make special grants. The canal is now little used owing to its small size and the increased power and range of steam fishing vessels. In the commissioners is also vested the Crinan canal (*q.v.*).

**CALEMBERG**, the name of a district, including the town of Hanover, formerly part of the duchy of Brunswick. It received its name from a castle near Schulenburg, and is traversed by the rivers Weser and Leine, its area being about 1,050 square miles. The district was given to various cadets of the ruling house of Brunswick, one of these being Ernest Augustus, afterwards elector of Hanover, and the ancestor of the Hanoverian kings of Great Britain and Ireland.

**CALENDAR**, so called from the Roman Calends or Kalends, a method of distributing time into certain periods adapted to the purposes of civil life, as hours, days, weeks, months, years, etc.

The *solar day* is distinguished by the daily revolution of the earth and the alternation of light and darkness. The *solar year* completes the circle of the seasons. The phases of the moon yield the *month*. The solar day, the solar year, and the lunar month, or lunation, are called the *natural* divisions of time. The hour, the week, and the civil month are conventional divisions.

**Day, Week and Month.**—The subdivision of the day (*q.v.*) into twenty-four parts, or hours combines a natural with a conventional division. The week, a period of seven days, having no reference whatever to the celestial motions, might have been suggested by the phases of the moon, or by the number of the planets known in ancient times, an origin which is rendered more probable from the names universally given to the different days of which it is composed.

The English names of the days are derived from the Saxon. The ancient Saxons had borrowed the week from some Eastern nation, and substituted the names of their own divinities for those of the gods of the East.

| Latin          | English    | Saxon          |
|----------------|------------|----------------|
| Dies Solis.    | Sunday.    | Sun's day.     |
| Dies Lunae.    | Monday.    | Moon's day.    |
| Dies Martis.   | Tuesday.   | Tiw's day.     |
| Dies Mercurii. | Wednesday. | Woden's day.   |
| Dies Jovis.    | Thursday.  | Thor's day.    |
| Dies Veneris.  | Friday.    | Frigg's day.   |
| Dies Saturni.  | Saturday.  | Seterne's day. |

Long before the exact length of the year was determined, it must have been perceived that the synodic revolution of the moon is accomplished in about 29½ days. Twelve lunations, therefore, form a period of 354 days, which differs only by about 11½ days from the solar year. From this circumstance has arisen the prac-

tice of dividing the year into twelve months. But in the course of a few years the accumulated difference between the solar year and twelve lunar months would become considerable, and have the effect of transporting the commencement of the year to a different season. To avoid this inconvenience some peoples have abandoned the moon altogether, and regulate their year by the course of the sun. The month, however, being a convenient period of time, has retained its place in the calendars of all nations, and usually denotes an arbitrary number of days approaching to the twelfth part of a solar year.

**Year.**—The year is either astronomical or civil. The solar astronomical year is the period of time in which the earth performs a revolution in its orbit about the sun, or passes from any point of the ecliptic to the same point again; and consists of 365 days 5 hours 48 min. and 46 sec. of mean solar time. The civil year is that which is employed in chronology, and varies among different peoples, both in respect of the season at which it commences and of its subdivisions. When regard is had to the sun's motion alone, the regulation of the year, and the distribution of the days into months, may be effected without much trouble; but the difficulty is greatly increased when it is sought to reconcile solar and lunar periods, or to make the subdivisions of the year depend on the moon, and at the same time to preserve the correspondence between the whole year and the seasons.

In the arrangement of the civil year, two objects are sought to be accomplished—first, the equable distribution of the days among twelve months; and secondly, the preservation of the beginning of the year at the same distance from the solstices or equinoxes. Now, as the year consists of 365 days and a fraction, and 365 is a number not divisible by 12, the months can not all be of the same length and at the same time include all the days of the year. By reason also of the fractional excess of the length of the year above 365 days, the years cannot all contain the same number of days if the epoch of their commencement remains fixed; for the day and the civil year must necessarily be considered as beginning at the same instant; and therefore the extra hours cannot be included in the year till they have accumulated to a whole day. As soon as this has taken place, an additional day must be given to the year.

The civil calendar of all European countries has been borrowed from that of the Romans. At the time of Julius Caesar, the civil equinox differed from the astronomical by three months, so that the winter months were carried back into autumn and the autumnal into summer.

Caesar abolished the use of the lunar year and the intercalary month, and regulated the civil year entirely by the sun. With the advice and assistance of Sosigenes, he fixed the mean length of the year at 365 $\frac{1}{4}$  days, and decreed that every fourth year should have 366 days, the other years having each 365. The first Julian year commenced with the 1st of January of the 46th before the birth of Christ, and the 708th from the foundation of the city.

It may be recorded that evidence has now come to light of the existence in earlier days of a calendar based on a standard year starting from noon on our February 25th.

For many years it was imagined that Caesar readjusted the year so that the first, third, fifth, seventh, ninth and eleventh months, that is, January, March, May, July, September and November should have each thirty-one days, and the other months thirty, excepting February, which in common years should have only twenty-nine, but every fourth year thirty days. But no ancient or modern authority supports this view, which is a flat contradiction of what Macrobius says in his *Saturnalia* 1, 14, 7, statements that are repeated in effect in section 9. Most modern authorities are agreed that much of the suggestion about Augustan activities is unwarranted and that Augustus had nothing to do with the lengthening of the month bearing his name.

The additional day which occurred every fourth year was given to February, as being the shortest month, and this additional or intercalary day was called *bis-sexta calendas*.

Although the Julian method of intercalation is perhaps the most convenient that could be adopted, yet, as it supposes the year too long by 11 minutes 14 seconds, the real error amounts

to a day in 128 years. In the course of a few centuries, however, the equinox sensibly retrogrades towards the beginning of the year. In order to restore the equinox to its former place, Pope Gregory XIII. directed ten days to be suppressed in the calendar; and as the error of the Julian intercalation was now found to amount to three days in 400 years, he ordered the intercalations to be omitted on all the centenary years excepting those which are multiples of 400.

According to modern astronomy the mean geocentric motion of the sun in longitude, from the mean equinox during a Julian year of 365.25 days, is  $360^{\circ} + 27''.685$ . Thus the mean length of the solar year is  $\frac{360^{\circ}}{360^{\circ} + 27''.685} \times 365.25 = 365.2422$  days, or 365 days 5 hours 48 min. 46 sec. Now the Gregorian rule gives 97 intercalations in 400 years; 400 years therefore contain  $365 \times 400 + 97$ , that is, 146,097 days; and consequently one year contains 365.2425 days, or 365 days 5 hours 49 min. 12 sec. This exceeds the true solar year by 26 seconds, which amount to a day in 3,323 years. It has therefore been proposed to correct the Gregorian rule by making the year 4000 and all its multiples common years. With this correction the rule of intercalation is as follows:—

Every year the number of which is divisible by 4 is a leap year, excepting the last year of each century, which is a leap year only when the number of the century is divisible by 4; but 4,000, and its multiples, 8,000, 12,000, 16,000, etc., are common years. Thus the uniformity of the intercalation, by continuing to depend on the number four, is preserved, and by the last correction the beginning of the year would not vary more than a day from its present place in two hundred centuries.

**The Lunar Year.**—The lunar year, consisting of twelve lunar months, contains only 354 days; its commencement consequently anticipates that of the solar year by eleven days, and passes through the whole circle of the seasons in about 34 lunar years. It being so obviously ill-adapted to the computation of time, almost all nations employ some method of intercalation, by means of which the beginning of the year is retained at nearly the same fixed place in the seasons.

**Ecclesiastical Calendar.**—The ecclesiastical calendar which is adopted in all the Catholic and most of the Protestant countries of Europe is luni-solar, being regulated partly by the solar, and partly by the lunar year, a circumstance which gives rise to the distinction between the movable and immovable feasts. By the 2nd century of our era, disputes had arisen among the Christians respecting the proper time of celebrating Easter, which governs all the other movable feasts. The Jews celebrated their passover on the 14th day of the *first month*, that is to say, the lunar month of which the 14th day either falls on, or next follows, the day of the vernal equinox. Most Christian sects agreed that Easter should be celebrated on a Sunday. Others followed the example of the Jews, and adhered to the 14th of the moon; but these, the minority, were accounted heretics, and received the appellation of Quartodecimans. The council of Nicaea, in the year 325, ordained that the celebration of Easter should thenceforth always take place on the Sunday which immediately follows the full moon that happens upon, or next after, the day of the vernal equinox. Should the 14th of the moon, which is regarded as the day of full moon, happen on a Sunday, the celebration of Easter was deferred to the Sunday following, in order to avoid concurrence with the Jews and the above-mentioned heretics. The observance of this rule renders it necessary to reconcile three periods which have no common measure, namely, the week, the lunar month, and the solar year; and as this can only be done approximately, and within certain limits, the determination of Easter is an affair of considerable nicety and complication.

**Dominical Letter.**—The first problem which the construction of the calendar presents is to connect the week with the year, or to find the day of the week corresponding to a given day of any year of the era. As the number of days in the week and the number in the year are prime to one another, two successive years cannot begin with the same day; for if a common year begins, for example, with Sunday, the following year

will begin with Monday, and if a leap year begins with Sunday, the year following will begin with Tuesday. For the sake of greater generality, the days of the week are denoted by the first seven letters of the alphabet, A, B, C, D, E, F, G, which are placed in the calendar beside the days of the year, so that A stands opposite the first day of January, B opposite the second, and so on to G, which stands opposite the seventh; after which A returns to the eighth, and so on through the 365 days of the year. Now if one of the days of the week, Sunday for example, is represented by E, Monday will be represented by F, Tuesday by G, Wednesday by A, and so on; and every Sunday through the year will have the same character E, every Monday F, and so with regard to the rest. The letter which denotes Sunday is called the *Dominical Letter*, or the *Sunday Letter*; and when the dominical letter of the year is known, the letters which respectively correspond to the other days of the week become known at the same time.

**Solar Cycle.**—In the Julian calendar the dominical letters are readily found by means of a short cycle, in which they recur in the same order without interruption. The number of years in the intercalary period being four, and the days of the week being seven, their product is  $4 \times 7 = 28$ ; twenty-eight years is therefore a period which includes all the possible combinations of the days of the week with the commencement of the year. This period, the *Solar Cycle*, or the *Cycle of the Sun*, restores the first day of the year to the same day of the week. At the end of the cycle the dominical letters return again in the same order on the same days of the month; hence a table of dominical letters, constructed for twenty-eight years, will serve to show the dominical letter of any given year from the commencement of the era to the Reformation. The cycle, though probably not invented before the time of the council of Nicaea, is regarded as having commenced nine years before the era, so that the year *one* was the tenth of the solar cycle. To find the year of the cycle, we have therefore the following rule:—*Add nine to the date, divide the sum by twenty-eight; the quotient is the number of cycles elapsed, and the remainder is the year of the cycle.* Should there be no remainder, the proposed year is the twenty-eighth or last of the cycle. In order to make use of the solar cycle in finding the dominical letter, it is necessary to know that the first year of the Christian era began with Saturday. The dominical letter of that year, which was the tenth of the cycle, was consequently B. The following year, or the 11th of the cycle, the letter was A; then G. The fourth year was bissextile, and the dominical letters were F, E; the following year D, and so on. In this manner it is easy to find the dominical letter belonging to each of the twenty-eight years of the cycle. But at the end of a century the order is interrupted in the Gregorian calendar by the secular suppression of the leap year; hence the cycle can only be employed during a century. In the reformed calendar the intercalary period is four hundred years, which number being multiplied by seven, gives two thousand eight hundred years as the interval in which the coincidence is restored between the days of the year and the days of the week.

**Lunar Cycle and Golden Number.**—In connecting the lunar month with the solar year, the framers of the ecclesiastical calendar adopted the lunar cycle, and organized the distribution of months. The lunations are supposed to consist of twenty-nine and thirty days alternately, or the lunar year of 354 days; and in order to make up nineteen solar years, six intercalary months, of thirty days each, are introduced in the course of the cycle, and one of twenty-nine days is added at the end. This gives  $19 \times 354 + 6 \times 30 + 29 = 6,935$  days, to be distributed among 235 lunar months. But every leap year one day must be added to the lunar month in which the 29th of February is included. Now if leap year happens on the first, second or third year of the period, there will be five leap years in the period, but only four when the first leap year falls on the fourth. In the former case the number of days in the period becomes 6,940 and in the latter 6,939. The mean length of the cycle is therefore 6,939½ days, agreeing exactly with nineteen Julian years.

By means of the lunar cycle the new moons of the calendar

were indicated before the Reformation. As the cycle restores these phenomena to the same days of the civil month, they will fall on the same days in any two years which occupy the same place in the cycle; consequently a table of the moon's phases for 19 years will serve for any year whatever when we know its number in the cycle. This number is called the *Golden Number*, either because it was so termed by the Greeks, or because it was usual to mark it with red letters in the calendar. The golden numbers were introduced into the calendar about the year 530, but disposed as they would have been if they had been inserted at the time of the council of Nicaea. The cycle is supposed to commence with the year in which the new moon falls on the 1st of January, which took place the year preceding the commencement of our era. Hence, to find the golden number  $N$ , for any year  $x$ , we have  $N = \left( \frac{x+1}{19} \right)_r$ , which gives the following

rule: *Add 1 to the date, divide the sum by 19; the quotient is the number of cycles elapsed, and the remainder is the Golden Number.* When the remainder is 0, the proposed year is of course the last or 19th of the cycle. The new moons, determined in this manner, may differ from the astronomical new moons sometimes as much as two days, because the sum of the solar and lunar inequalities, which are compensated in the whole period, may amount in certain cases to 10°, and thereby cause the new moon to arrive on the second day before or after its mean time.

**Dionysian Period.**—The cycle of the sun brings back the days of the month to the same day of the week; the lunar cycle restores the new moons to the same day of the month; therefore  $28 \times 19 = 532$  years, includes all the variations in respect of the new moons and the dominical letters, and is consequently a period after which the new moons again occur on the same day of the month and the same day of the week. This is called the *Dionysian* or *Great Paschal Period*, from its having been employed by Dionysius Exiguus, familiarly styled "Denys the Little," in determining Easter Sunday. It was, however, first proposed by Victorius of Aquitaine, who had been appointed by Pope Hilary to revise and correct the church calendar. Hence it is also called the *Victorian Period*. It continued in use till the Gregorian reformation.

**Cycle of Indiction.**—Besides the solar and lunar cycles, there is a third of 15 years, called the cycle of indiction, frequently employed in the computations of chronologists. This period has reference to certain judicial acts which took place at stated epochs under the Greek emperors. Its commencement is referred to the 1st of January of the year 313 of the common era. By extending it backwards, it will be found that the first of the era was the fourth of the cycle of indiction. The number of any year in

this cycle will therefore be given by the formula  $\left( \frac{x+3}{15} \right)_r$ , that is to say, *add 3 to the date, divide the sum by 15, and the remainder is the year of the indiction.* When the remainder is 0, the proposed year is the fifteenth of the cycle.

**Julian Period.**—The Julian period, proposed by the celebrated Joseph Scaliger as an universal measure of chronology, is formed by taking the continued product of the three cycles of the sun, of the moon, and of the indiction, and is consequently  $28 \times 19 \times 15 = 7,980$  years. In the course of this long period no two years can be expressed by the same numbers in all the three cycles. Hence, when the number of any proposed year in each of the cycles is known, its number in the Julian period can be determined.

**Reformation of the Calendar.**—The ancient Church Calendar was founded on two suppositions, both erroneous, namely, that the year contains 365½ days and that 235 lunations are exactly equal to 19 solar years. It could not therefore long continue to preserve its correspondence with the seasons, or to indicate the days of the new moons with the same accuracy. Pope Gregory XIII. issued a brief in the month of March 1582, in which he abolished the use of the ancient calendar, and substituted that which has since been received in almost all Christian countries under the name of the *Gregorian Calendar* or *New Style*. The author of the system adopted by Gregory was Aloysius Lilius,

or Luigi Lilio Ghiraldi, a learned astronomer and physician of Naples, who died, however, before its introduction; but the individual who most contributed to give the ecclesiastical calendar its present form, and who was charged with all the calculations necessary for its verification, was Clavius, by whom it was completely developed and explained in a great folio treatise of 800 pages, published in 1603.

In order to restore the beginning of the year to the same place in the seasons that it had occupied at the time of the council of Nicaea, Gregory directed the day following the feast of St. Francis, that is to say the 5th of October, to be reckoned the 15th of that month. By this regulation the vernal equinox which then happened on the 11th of March was restored to the 21st. From 1582 to 1700 the difference between the old and new style continued to be ten days; but 1700 being a leap year in the Julian calendar, and a common year in the Gregorian, the difference of the styles during the 18th century was eleven days. The year 1800 was also common in the new calendar, and, consequently, the difference in the 19th century was twelve days. From 1900 to 2100 inclusive it is thirteen days.

The restoration of the equinox to its former place in the year and the correction of the intercalary period, were attended with no difficulty; but Lilius had also to adapt the lunar year to the new rule of intercalation. The lunar cycle contained 6,939 days 18 hours, whereas the exact time of 235 lunations, as we have already seen, is  $235 \times 29.530588 = 6,939$  days 16 hours 31 minutes. The difference, 1 hour 29 minutes, amounts to a day in 308 years, so that at the end of this time the new moons occur one day earlier than they are indicated by the golden numbers. Lilius rejected the golden numbers from the calendar, and supplied their place by another set of numbers called *Epacts*, a term of Greek origin, which, employed in the calendar, signifies the moon's age at the beginning of the year. The common solar year containing 365 days, and the lunar year only 354 days, the difference is eleven; whence, if a new moon fall on the 1st of January in any year, the moon will be eleven days old on the first day of the following year, and twenty-two days on the first of the third year. The numbers eleven and twenty-two are therefore the epacts of those years respectively. Another addition of eleven gives thirty-three for the epact of the fourth year; but in consequence of the insertion of the intercalary month in each third year of the lunar cycle, this epact is reduced to three. In like manner the epacts of all the following years of the cycle are obtained by successively adding eleven to the epact of the former year, and rejecting thirty as often as the sum exceeds that number. Two equations or corrections must be applied, one depending on the error of the Julian year, which is called the solar equation; the other on the error of the lunar cycle, which is called the lunar equation. The solar equation occurs three times in 400 years, namely, in every secular year which is not a leap year; for in this case the omission of the intercalary day causes the new moons to arrive one day later in all the following months, so that the moon's age at the end of the month is one day less than it would have been if the intercalation had been made, and the epacts must accordingly be all diminished by unity. Thus the epacts 11, 22, 3, 14, etc., become 10, 21, 2, 13, etc. On the other hand, when the time, by which the new moons anticipate the lunar cycle, amounts to a whole day, which, as we have seen, it does in 308 years, the new moons will arrive one day earlier, and the epacts must consequently be increased by unity. Thus the epacts 11, 22, 3, 14, etc., in consequence of the lunar equation, become 12, 23, 4, 15, etc. In order to preserve the uniformity of the calendar, the epacts are changed only at the commencement of a century; the correction of the error of the lunar cycle is therefore made at the end of 300 years. In the Gregorian calendar this error is assumed to amount to one day in 312½ years or eight days in 2,500 years, an assumption which requires the line of epacts to be changed seven times successively at the end of each period of 300 years, and once at the end of 400 years; and, from the manner in which the epacts were disposed at the Reformation, it was found most correct to suppose one of the periods of 2,500 years to terminate with the year 1800.

The years in which the solar equation occurs, counting from the Reformation, are 1700, 1800, 1900, 2100, 2200, 2300, 2500, etc. Those in which the lunar equation occurs are 1800, 2100, 2400, 2700, 3000, 3300, 3600, 3900, after which, 4300, 4600 and so on. When the solar equation occurs, the epacts are diminished by unity; when the lunar equation occurs, the epacts are augmented by unity; and when both equations occur together, as in 1800, 2100, 2700, etc., they compensate each other, and the epacts are not changed.

In consequence of the solar and lunar equations, it is evident that the epact or moon's age at the beginning of the year, must, in the course of centuries, have all different values from one to 30 inclusive, corresponding to the days in a full lunar month.

The use of the epacts is to show the days of the new moons, and thus the moon's age. If the last lunation of any year ends, for example, on the 2nd of December, the new moon falls on the 3rd; and the moon's age on the 31st, or at the end of the year, is twenty-nine days. The epact of the following year is therefore twenty-nine. Now, that lunation having commenced on the 3rd of December, and consisting of thirty days, will end on the 1st of January. The 2nd of January is therefore the day of the new moon, which is indicated by the epact 29. In like manner, if the new moon fell on Dec. 4 the epact of the following year would be 28, which, to indicate the day of the next new moon, must correspond to Jan. 3.

**Easter.**—The principal use of the calendar is to find Easter, which, according to the traditional regulation of the council of Nice, must be determined from the following conditions:—1st, Easter must be celebrated on a Sunday; 2nd, this Sunday must follow the 14th day of the paschal moon, so that if the 14th of the paschal moon falls on a Sunday then Easter must be celebrated on the Sunday following; 3rd, the paschal moon is that of which the 14th day falls on or next follows the day of the vernal equinox; 4th, the equinox is fixed invariably in the calendar on the 21st of March. This regulation is to be construed according to the tabular full moon as determined from the epact, and not by the true full moon, which, in general, occurs one or two days earlier.

From these conditions it follows that the paschal full moon, or the 14th of the paschal moon, cannot happen before the 21st of March, and that Easter in consequence cannot happen before the 22nd of March. If the 14th of the moon falls on the 21st, the new moon must fall on the 8th; for  $21 - 13 = 8$ ; and the paschal new moon cannot happen before the 8th; for suppose the new moon to fall on the 7th, then the full moon would arrive on the 20th, or the day before the equinox. The following moon would be the paschal moon. But the fourteenth of this moon falls at the latest on the 18th of April, or 29 days after the 20th of March; for by reason of the double epact that occurs at the 4th and 5th of April, this lunation has only 29 days. Now, if in this case the 18th of April is Sunday, then Easter must be celebrated on the following Sunday, or the 25th of April. Hence Easter Sunday cannot happen earlier than the 22nd of March, or later than the 25th of April.

The complicated, though highly ingenious method, invented by Lilius, for the determination of Easter and the other movable feasts, is entirely independent of astronomical tables, or indeed of any celestial phenomena whatever; so that all chances of disagreement arising from the inevitable errors of tables, or the uncertainty of observation, are avoided, and Easter determined without the possibility of mistake. But this advantage is only procured by the sacrifice of some accuracy; for the conditions of the problem are not always exactly satisfied, nor can they be always satisfied by any similar method of proceeding. The equinox is fixed on the 21st of March, though the sun enters Aries generally on the 20th of that month, sometimes even on the 19th. A full moon may therefore arrive after the true equinox, and yet precede the 21st of March. This would not be the paschal moon of the calendar, though it undoubtedly ought to be so if the intention of the council of Nice were rigidly followed. The new moons indicated by the epacts also differ from the astronomical new moons, and even from the mean new moons, in gen-

eral by one or two days. In imitation of the Jews, who counted the time of the new moon, not from the moment of the actual phase, but from the time the moon first became visible after the conjunction, the fourteenth day of the moon is regarded as the

full moon. But the moon is in opposition generally on the 16th day; therefore, when the new moons of the calendar nearly concur with the true new moons, the full moons are considerably in error. The epacts are also placed so as to indicate the full moons generally one or two days after the true full moons; but this was done to avoid the chance of concurring with the Jewish passover, which the framers of the calendar seem to have considered a greater evil than that of celebrating Easter a week too late.

In 1923 a committee was appointed by the League of Nations to consider the reform of the Calendar and the establishment of a fixed Easter. No evidence was discovered of a wide desire to alter the calendar, but there was much secular support and a certain sympathy from some religious authorities in favour of a fixed Easter. In 1928 a private member's bill was introduced into the British parliament, and duly passed in August (the Easter Act); it provided that, from a date to be fixed by an Order in Council, Easter day shall be the first Sunday following the second Saturday in April. This Order in Council may not be made, however, until a draft of the order has been approved by parliament—a safeguard intended to ensure uniform action with other countries, and to prevent the taking of any definite step before being assured of the acknowledged support of the religious denominations.

The principal church feasts depending on Easter, and the times of their celebration are as follows:—

|  |        |         |                |
|--|--------|---------|----------------|
| Septuagesima Sunday . . . . .            | } is { | 9 weeks | before Easter. |
| First Sunday in Lent . . . . .           |        | 6 weeks |                |
| Ash Wednesday . . . . .                  |        | 46 days |                |
| Rogation Sunday . . . . .                | } is { | 5 weeks | after Easter.  |
| Ascension Day or Holy Thursday . . . . . |        | 39 days |                |
| Pentecost or Whitsunday . . . . .        |        | 7 weeks |                |
| Trinity Sunday . . . . .                 |        | 8 weeks |                |

The Gregorian calendar was introduced into Spain, Portugal and part of Italy the same day as at Rome. In France it was received in the same year in the month of December, and by the

Catholic states of Germany the year following. In the Protestant states of Germany the Julian calendar was adhered to till the year 1700, when it was decreed by the diet of Regensburg that the new style and the Gregorian correction of the intercalation should be adopted. Instead, however, of employing the golden numbers and epacts for the determination of Easter and the movable feasts, it was resolved that the equinox and the paschal moon should be found by astronomical computation from the Rudolphine tables. But this method was abandoned in 1774 at the instance of Frederick II., king of Prussia. In Denmark and Sweden the reformed calendar was received about the same time as in the Protestant states of Germany. Russia adhered to the Julian reckoning, until it was superseded by the Soviet Government, which introduced the Gregorian reckoning.

In Great Britain the Calendar (New Style) Act 1750 was passed for the adoption of the new style in all public and legal transactions. The difference of the two styles, which then amounted to eleven days, was removed by ordering the day following the 2nd of September of the year 1752 to be accounted the 14th of that month; and in order to preserve uniformity in future, the Gregorian rule of intercalation respecting the secular years was adopted. At the same time, the commencement of the legal year was changed from the 25th of March to the 1st of January. In Scotland, January 1st was adopted for New Year's Day from 1600, according to an act of the privy council in December 1599. This fact is of importance with reference to the date of legal deeds executed in Scotland between that period and 1751, when the change was effected in England. With respect to the movable feasts, Easter is determined by the rule laid down by the council of Nice; but instead of employing the new moons and epacts, the golden numbers are prefixed to the days of the full moons. In those years in which the line of epacts is changed in the Gregorian calendar, the golden numbers are removed to different days, and of course a new table is required whenever the solar or lunar equation occurs. The golden numbers have been placed so that Easter may fall on the same day as in the Gregorian calendar. The calendar of the Church of England is therefore from century to century the same in form as the old Roman calendar, excepting that the golden numbers indicate the full moons instead of the new moons. The Orthodox Church in Greece has adopted a modified Gregorian calendar, with a 900 year cycle. The Orthodox Church in Greece has also adopted the Gregorian system presumably in this form. Easter is computed by the actual, not the simplified ecclesiastical moon. The meridian for calculations is that of Jerusalem.

**BIBLIOGRAPHY.**—The principal works on the calendar are the following:—Clavius, *Romani Calendarii a Gregorio XIII. P.M. restituiti Explicatio* (Rome, 1603); *L'Art de vérifier les dates*; Lalande, *Astronomie*, tome ii.; *Traité de la sphère et du calendrier*, par M. Revard (Paris, 1816); Delambre, *Traité de l'astronomie théorique et pratique*, tome iii.; *Histoire de l'astronomie moderne*; *Methodus technica brevis, perfacilis, ac perpetua construendi Calendarium Ecclesiasticum, Stylo tam novo quam vetere, pro cunctis Christianis Europae populi, etc.*, auctore Paulo Tittel (Göttingen, 1816); *Formole analitiche pel calcolo della Pasqua, e correzione di quello di Gauss, con critiche osservazioni su quanto ha scritto del calendario il Delambri*, di Lodovico Ciccolini (Rome, 1817); E. #### PRIMITIVE

The calendar of the modern civilized world is a system of time-reckoning which consists of units or divisions and subdivisions which have a strictly limited duration: years, months, days, hours, minutes, and seconds. To define a certain point or space in the lapse of time these units are simply numbered. They serve not only for the indication and reckoning of time but also for its measurement. Consequently units of the same order ought always to have the same length, but here natural causes and tradition create certain exceptions such as months of 31, 30, 29 and 28 days respectively, and, in the lunisolar calendar, years of alternately 12 and 13 months. Primitive man clings always to the concrete. In his experience certain natural phenomena constantly

recur, *e.g.*, the sun and the new moon, and certain phenomena recur in the same order, *e.g.*, snow, the sprouting of the leaves, the ripening of certain fruits, and the falling of the leaves, etc. By reference to such concrete phenomena he is able to indicate a certain time. Time indications of primitive man are not durational like the unit of any system of time-reckoning, but indefinite.

Again, the phenomena referred to are often of unequal or indeterminate duration; they overlap or leave gaps, and cannot be numerically grouped together. Consequently we have to deal with a time-reckoning by time-indications only, or briefly, a *discontinuous time-reckoning*. A definite and constantly-recurring phenomenon, *e.g.*, a certain day, a certain month, a certain year, is indicated by referring to a certain event or natural phenomenon connected with it as, for instance, the day of the waning of the moon, the month in which the leaves fall, the year of the cattle disease, etc. It is possible to count time by reckoning a single phenomenon, recurring constantly within a certain unit, which has not yet been conceived as such. The child who has seen ten snows or ten harvests is ten years old. Nine new moons appear before the woman bears her child. This mode of counting time may be called the *pars-pro-toto* method. Presuming that the indication of concrete phenomena following one another in the regular succession of Nature has preceded the abstract numerical indication of time, the origin of time-reckoning is to be found, not in any system, however simple, but in the time-indications referring to concrete phenomena and in the *pars-pro-toto* method of counting time referring to these concrete phenomena.

Celestial phenomena are of outstanding importance. The units of time-reckoning depend on the motions of the heavenly bodies, and the more intimately these enter into the life of man, the more important they are for the calendar. The (solar) day of 24 hours is determined by the rotation of the earth on its axis. The year is the period of a revolution of the earth about the sun. The varying height of the sun and duration of its appearance are ultimately the causes of the seasonal variations of the climate and the life of Nature. By the term "months," the lunar or moon-month is understood, unless expressly stated otherwise. Our months have nothing to do with the moon but are simply subdivisions of the solar year, the length of which comes near that of a lunar month. The lunar month is the interval between two consecutive new moons, and comprises slightly more than 29½ days.

Primitive man knows the stars and notes their appearances. It can be observed that some constellations appear in the heavens in the winter, others in the summer. The sun seems to move more slowly than the stars owing to the motion of the earth, and in the course of a year the sun runs through the zodiac backwards. The stars gain every day 3 min. 56 secs. on the sun, *i.e.*, a particular star culminates every day that much earlier than the sun. Primitive man rises and goes to bed with the sun. At dawn he notices the stars that are shining in the east and are soon to vanish before the light of the sun. In the same way he observes at evening, before he goes to rest, the stars on the western horizon which soon afterwards set there. The star of which he is just able to catch a glimpse in the east in the morning twilight, will stand a little higher next morning, and it will rise earlier every morning until after about half a year its rising will take place in the evening twilight. The first visible appearance of a star in the morning twilight is termed its *heliacal rising*, and the last visible setting of a star in the evening twilight is called its *heliacal setting*. The observation of the stars provides a means of determining the time from quite regular phenomena, whereas the variations of the seasons in different years may be considerable.

**The Day.**—The notion of the day of 24 hours, comprising a day and a night, is a late development, so late indeed that most languages lack a proper word for it. Some primitive peoples use such expressions as "light and darkness," "sun-darkness" to describe it. But this is rare. The days are counted according to the *pars-pro-toto* method in "suns," "nights," "sleeps," "dawns" (Homer); whoever has slept six nights on the way has undertaken a six days' journey. The counting in nights was especially favoured by the old Teutonic peoples (*cf.* the expressions "fort-night," "sennight"). For the indication of a point of time within

the day, reference to the course of the sun is very common, and this indication can be given by a gesture. More rarely the position or the length of the shadow is referred to, and still more rarely a staff is used as a sun-dial. In Iceland and the northern parts of Scandinavia the time of the day was determined by mountain peaks or stone heaps above which the sun stood at a certain time of the day. The names of the divisions of the day are derived from natural phenomena, *e.g.*; day-break, twilight, sun-rise, morning, noon, etc., and from the common daily occupations. Examples of these are the Homeric description of evening as "the time when the oxen are unyoked," and the Irish *im-buarach* (morning), "at the yoking of the oxen." Many primitive peoples have elaborate series of expressions of this kind. The night is the time of complete darkness and rest, and time indications are therefore scanty. The cock-crow sometimes serves this purpose and, more rarely, the stars are used by peoples who have studied them to determine the lapse of the night, because the position of the stars in the night-sky change every day. These indications do not imply a strictly limited duration as our "hours" do. To indicate a definite time-limit, some activity, the duration of which is known, is referred to, *e.g.*, "the time in which one can cook a handful of vegetables," *i.e.*, an hour, "the frying of a locust," *i.e.*, a moment. Very often duration of time is indicated by reference to the time needed to traverse a well-known piece of road.

**The Seasons.**—The seasons are sometimes used to determine time within the year, but every seasonal occurrence, *e.g.*, the sowing, is used thus, and as these have a short duration, they are better suited to indicate time and much more widely used for this purpose. Thus in the classical examples in Hesiod, the cry of the migrating cranes shows the time of ploughing and sowing; when the snail climbs up the plants there should be no more digging in the vineyards; when the thistle blossoms summer has come; the sea can be navigated when the fig-tree sprouts, etc. Similar time-indications are still used by peasants. Among primitive peoples they are common, and not only among the agricultural ones. The main seasons differ according to the zones. In the tropics there are dry and rainy seasons, sometimes two of each; the trade-winds and the monsoons and the intervening calms. Although the seasons recur more regularly in the tropics and the sub-tropical regions than in northern climates, they are of varying length, and there are greater and smaller seasons and seasonal points, which overlap. Consequently their number is varying and indefinite. We may, *e.g.*, speak of the year as consisting of winter and summer or of spring, summer, harvest and winter. The old Teutons are said to have had only three seasons: winter, spring, and summer. The climatic conditions of the country are of paramount importance. The seasons are seldom adapted for true calendrical purposes, as only with some violence can they be systematized into periods of a definite number of days as the early Scandinavians did with the winter and summer.

**The Year.**—A cycle of seasons make up a year, and while all peoples have an idea of the year in the sense that the same cycle of seasons always recurs in a certain order, they seldom consciously unite the different seasons into a year. The notion of the year is a comparatively late and gradual development acquired by means of selection, regulation and systemization of the seasons. Some peoples reckon in half-years—two seasons—without joining them together, as in East Africa where there are two rainy seasons, and in the East Indian Archipelago, where the south-west and the north-east monsoons each blow for about half a year. Some peoples count one dry and one rainy season without combining them into a year. An incomplete year consisting of about ten months is found especially among some agricultural peoples, but is in reality the vegetation year, from the commencement of agricultural work to its end, when the harvest is housed; the vacant period is simply passed over. Such reckonings are known to be made in north-east Asia, the East Indian Archipelago and Central Africa. If the vacant period were added to this cycle, the natural year would be attained, but its length is indefinite and may vary according to the accidental variations of the climate. A calendrical year is attained only by the aid of the

stars or the months. For the counting of years, the *pars-pro-toto* method is employed. The Hottentots reckon the age of their cattle and sheep by the calving and lambing periods. The Algonquin and the old Scandinavians counted by winters, the fellahs of Palestina and the Inca people by harvests, etc.

Primitive peoples are primarily concerned with the age of a man in relation to his fellows, that is, whether he be older or younger than another, and from this the counting in generations is evolved. Years are not numbered but designated by reference to some well-known event which took place in a certain year, e.g., a plague, cattle disease, war, migration, unusual snowfall, etc. Long lists of such designations of years are quoted from the Herero and some North American Indians. The same method was employed in Babylonia and in pre-Mohammedan Arabia. Higher civilized peoples refer to their chiefs or kings and the years of their reign. If the highest authority is changed annually, the years are designated by their names: thus, in Rome, the year was known by the name of the consul and in Greece by that of the archon. This method is unwieldy, for a long series of names must be kept in mind in correct order.

**The Stars.**—Time indications by seasons are inexact because the phenomena to which they are related are fluctuating. Observation of the stars provides a means of indicating time within the year with greater precision. Most primitive peoples know the stars well, and some extremely well, e.g., the South American Indians, the Polynesians and Melanesians. Hesiod and many classical authors indicate time by the rising and setting of certain stars: the vines should be pruned before the evening rising of Arcturus; the morning setting of the Pleiades is the time of sowing and of the autumn storms. Counting by the stars, particularly by the Pleiades, is still practised by certain primitive peoples. The appearance of certain stars is connected with seasonal phenomena and used for determining agricultural occupations. Finally, a true notion of the year is formed by a few peoples when the period between a certain appearance of a star or constellation (principally the Pleiades) and its next appearance of the same kind, e.g., the heliacal rising, is noticed. The inhabitants of the Marquesas and some South American Indians call the year and the Pleiades by the same name. In this manner, by observing the heliacal rising of Sirius, the old Egyptians established the solar year, and from them it was adopted by Julius Caesar.

**The Moon.**—The course of the moon forms a shorter unit which steps in between day and year. The shorter period of time defined by it is easily kept in mind and noted at a glance. It has in itself nothing to do with the natural phases conditioned by the course of the sun. Time-reckoning according to the moon is by its nature continuous and strictly limited. The month is by its nature a definite and limited unit of time. One moon follows another with a brief interruption of only one or two days in which the moon is invisible. The phases of the moon represent a gradual waxing and waning, a continuous development. The principle of continuous time-reckoning is suggested by the moon. The days of the month are originally not counted but designated with reference to the shape of the moon and its position in the sky. The new moon and the full moon have a special prominence and are often hailed with rejoicing and feasting. Then the crescent of the waning moon is added. Many peoples distinguish the three phases of the waxing, the full and the waning moon; then further phases and the absence of the moon, "when it has gone to sleep," are added. The Polynesians and Micronesians have developed a system by which every day of the month has a name taken from the shape or the position of the moon. Other peoples, e.g., the Masai, the Hindus, etc., count the days of the light and the dark halves of the moon. The Greeks counted in decades after the three principal phases, but there are also traces of a division of the month into two parts. A division into four parts is but rarely found.

**The Month.**—The months are seldom counted, and then principally in regard to the months of pregnancy; but a month is designated by a natural phenomenon or seasonal occupation occurring in it, e.g., the blackberry month, sowing month, lambing month, etc. This naming was originally accidental. Sharp dis-

tinctions were not made, indeed were not possible. There was much overlapping, but from this material, by a kind of natural selection, a series of month-names came into being covering the course of the natural year. A number of such series have been found in all parts of the world except South America and Australia. A year of 13 months is reckoned by quite as many peoples as reckon 12 months.

**Inter- or Extra-calation.**—Here a fundamental difficulty appears, for the solar year has 365½ days; 12 months make 354 days, i.e., 10 days too little, 13 months 384 days, i.e., 19 days too much. So long as the month-names are accidental, or only some of the months are named and the two or three months not associated with definite occupations are neglected, the difficulty is passed over. But once a fixed series of months has arisen they soon cease to coincide with the natural phenomena and occupations after which they are named. If the series has 12 months, a month will come earlier than the natural phenomenon after which it is named. If the series has 13 months it will soon come after this phenomenon is over. The Dakota often had heated debates as to the existing month and the Pawnees sometimes became inextricably involved in their reckoning. The obvious remedy is to correct the reckoning after the occurrence of the natural phenomenon. In a 12-month series, for instance, the harvest month which came before the corn was ripe, is repeated; the first harvest month is then said to have been "lost" or "forgotten." In the 13-month series the month which came after the natural phenomenon is simply left out, and the following month in the series is reckoned. The means resorted to in the former case was the intercalation of a month and in the latter the extracalation of a month to restore the months to their relative position in the seasons, i.e., the solar year, indicated by their names. Thus came into existence the lunisolar year which follows both the sun and the moon, and consequently must have alternately 12 and 13 months. A still more exact means of detecting the deviation of the months and correcting it was attained by naming some or all of the months after the appearances of certain stars as, for instance, is the practice in north-west America, Polynesia and Melanesia. In Babylonia, before the middle of the third millennium B.C., the list of months had been fixed and a certain month had been singled out as the intercalary month. (From about 2000 B.C. it was one of the two months *Adarru* or *Ululu*.) The lunisolar year was regulated by empirical intercalation, which continued down to the Persian times. From Babylonia the Greeks took over the lunisolar year, but in the 7th century B.C. introduced a cyclical intercalation, the *octaëteris*, thus setting the problem of the scientific regulation of the calendar.

The natural year, being an ever-recurring cycle, has no proper new year, i.e., a point from which the year commences; the beginning of the year or of the list of month-names varies greatly therefore. But the agricultural year has a definite commencement and end. This end of the agricultural occupations is often celebrated by festivals. It forms the turning point of the year; a new period is entered upon. The European calendrical new year has its origin in the term at which the Roman Consul, after whom the year was named, entered upon his office.

**Solstices and Equinoxes.**—While the stars were often used for more accurately defining the time within the year, certain points in the course of the sun may be referred to, namely, the solstices and equinoxes (*q.v.*). This is, however, a more complicated observation which requires a fixed standing point and certain landmarks touched by the sun in its travel from north to south and inversely. In this manner the Eskimos, the Indians of Arizona, the Amazulu, etc., observe the most northern and southern points reached by the sun, its "houses" or "turning points." They were also known to Homer and Hesiod. The observation of the equinoxes is still more difficult; for this purpose the Incas had erected towers as artificial marks at Cuzco. Certain gifted and advanced peoples, the Eskimos, the Northern Scandinavians, the Polynesians and Melanesians, have made still more refined observations of the course of the sun, but on the whole even the simplest observations of this nature, viz., those of the solstices, play no important part in primitive time-reckoning.

**The Market-week.**—There is a wholly artificial period of fairly frequent occurrence among peoples who have sufficiently advanced in civilization to have a regular trade. This is the market-week, or the fixed period of days in which a market is held. It varies in length and lasts three days among the Muysca in Bogota, four among many West African tribes, five in Central America, the East Indian Archipelago and old Assyria, six among a tribe in Togo, eight among the ancient Romans (the *nundinae*), and ten among the Inca people. On the market day, especially in Africa, work is often forbidden, certain taboos are imposed, and religious ceremonies performed. The hypothesis has therefore been advanced that the Israelitish sabbath was by origin a market day, although the prohibition of work has been extended also to its original purpose of commerce.

**Methods of Reckoning.**—Finally many peoples use a tally or other device for counting days, moons, and years, and where a more refined science of time-reckoning is evolved it is in the hands of a special class, particularly the priests, who preserve this knowledge and regulate the calendar. Hence the close connection between the religious system and the calendar, for the celebration of the festivals and ceremonies at the right times as indicated by the calendar is the chief duty of the priests, who gathered great knowledge of times and seasons, of the holy days and the work days, of the links between man and the sun, the moon, and the stars. These and the seasons and the cycle of Nature are the material from which by long, hard thought, by patient observation, by ever subtler and more accurate calculation, modern systems of time-reckoning have been developed.

See Martin P. Nilsson, *Primitive Time-Reckoning* (1920).

#### CHINESE

For chronological purposes, the Chinese people, as elsewhere in the east of Asia, employ cycles of sixty to reckon their days, moons and years. The days are distributed in the calendar into cycles of sixty, in the same manner as ours are distributed into weeks, or cycles of seven. Each day of the cycle has a particular name, and as it is usual in mentioning dates, to give the name of the day along with that of the moon and the year, it is easy to verify the epochs of Chinese chronology. The order of the days in the cycle is never interrupted by any intercalation used to adjust the months or years. The moons of the civil year are also distinguished by their place in the cycle of sixty; and as the intercalary moons are not reckoned, because during one of these lunations the sun enters into no new sign, there are only twelve regular moons in a year, so that the cycle is renewed every five years. The cycle of sixty is formed of two subordinate cycles or series of characters, one of ten and the other of twelve, which are joined together so as to afford sixty different combinations. The names of the characters in the cycle of ten, which are called *celestial signs*, are:

1. Kia; 2. I; 3. Ping; 4. Ting; 5. Wu;
6. Ki; 7. K'eng; 8. Hsin; 9. Jen; 10. Kuei;

and in the series of 12, denominated *terrestrial signs*,

1. Tzū; 2. Chou; 3. Yin; 4. Mao; 5. Shin; 6. Ssü;
7. Wu; 8. We; 9. Shin; 10. Yu; 11. Hsü; 12. Hai.

The name of the first year, or of the first day, in the sexagenary cycle is formed by combining the first words in each of the above series; the second is formed by combining the second of each series, and so on to the tenth. For the next year the first word of the first series is combined with the eleventh of the second, then the second of the first series with the twelfth of the second, after this the third of the first series with the first of the second, and so on till the sixtieth combination, when the last of the first series concurs with the last of the second.

In the Chinese history translated into the Tatar dialect by order of the emperor K'ang-hi (d. 1721), the characters of the cycle begin to appear at the year 2357 B.C. From this it has been inferred that the Chinese empire was established previous to that epoch; but as the cycles can be extended backwards indefinitely, the inference can have very little weight. The characters given to that year 2357 B.C., are Keā-shin, which denote the 41st of the

cycle. We must, therefore, suppose the cycle to have begun 2397 B.C., or forty years before the reign of Yao. This is the epoch assumed by the authors of *L'art de vérifier les dates*. The mathematical tribunal has, however, from time immemorial counted the first year of the first cycle from the eighty-first of Yao, that is to say, from the year 2277 B.C.

Since the year 163 B.C. Chinese writers date the year from the accession of the reigning emperor. An emperor, on succeeding to the throne, gives a name to the years of his reign. The periods thus formed are called by the Chinese *Nien-hao* (year-name). According to this method of dating the years a new era commences with every reign; and the year corresponding to a Chinese date can only be found when we have before us a catalogue of the *Nien-hao*, with their relation to the years of our era. In modern China the native calendar is used side by side with the western one (*Hsi-li* or western reckoning). (X.)

#### EGYPTIAN

A solar year, a lunar month and a day unfortunately are incommensurable units of time, for a year contains roughly  $365\frac{1}{4}$  days and a month roughly  $29\frac{1}{2}$  days. From this fact arise the difficulties with which early constructors of calendars were confronted. The Egyptians appear to have begun with a lunar calendar. We have no contemporary evidence of this, but the writing of the word "month" with the moon-sign, the importance of the monthly and half-monthly festivals in later times, and the adoption of the month as a unit in the later calendar place it beyond doubt.

At a very early date, however, the Egyptians had begun to observe what is known as the heliacal rising of the star Sirius or Sothis, a conspicuous object in the Egyptian sky. A star is said to rise heliacally on the day on which it first appears again in the sky just before sunrise after being for some time invisible. The Egyptians noted that this rising corresponded very closely with the rise of the Nile, on which the agricultural welfare of the country depended. Small wonder then that they chose this for the first day of the year, and took the period between two such observed risings to form a unit of time which was convenient not only as being much longer than the old month, but as including a whole round of the seasons.

The next step was to subdivide the new unit, and here use was made both of the old months and of the changing seasons. Twelve nominal months of 30 days each gave 360 days, and the missing 5 days were added on at the end under the name of "days additional to the year." The months were grouped into three sets of four, the first four forming the inundation season, the second four the winter or sowing-time and the third four the summer or harvest.

Unfortunately the constructors of this calendar either overlooked or ignored the fact that every four years, as observation must have shown, Sothis rose a day later, *i.e.*, after a lapse of 366 and not 365 days, the reason being, as we now know, that the star-year, which is virtually identical with the solar year, measures about  $365\frac{1}{4}$  days. This error of theirs meant that their calendar got out of gear with the solar year, and consequently with the seasons, to the extent of one day every four years, and the error became greater and greater until eventually, after 1,460 ( $365 \times 4$ ) solar years, known as a Sothic Period, the calendrical New Year's Day had worked right round the seasons and come back to its correct place again. The Egyptians were not unaware of this absurdity, but it was not until quite late times that they sought to correct it by the insertion of an extra day every four years (Leap Year), and even then the attempt failed.

We know from the Latin writer Censorinus that the first day of the Egyptian calendar year coincided with the rising of Sothis in A.D. 139, and it must therefore have done the same thing 1,460 solar years earlier and so on, *i.e.*, in 1321 B.C., 2781 B.C., 4241 B.C., 5701 B.C., etc. Obviously it was at one of these moments that the calendar was introduced. Now the religious texts inscribed in the pyramids of the Fifth and Sixth Dynasties show that the calendar with its five extra days was then already in existence. Egyptologists consequently date the introduction of the calendar to 4241 B.C. or to 2781 B.C., according as they believe the pyramids

to be earlier or later than the latter date. A still higher date, e.g., 5701 B.C., is hardly likely.

The Egyptians used no unit of time longer than a year. Consequently they had no dating by eras in the modern sense. In very early times each year was named after some important event in it, e.g., "The year of the first smiting of the East," and was at the same time connected with the reigning king. Later, under the Fifth and Sixth Dynasties, the biennial cattle census was used for time reckoning, and the years of a king's reign were numbered alternately "The Year of the first (second, third, etc.), census" and "The Year after the first (second, third, etc.), census." Later still the years of the reign were numbered straightforwardly 1, 2, 3 and so on.

In early Egyptian documents the months bear no special names, being written merely as the first, second, third or fourth month of such and such a season. In the Persian period, however (6th cent. B.C.), there began to appear month names drawn from festivals which took place during the month; these names may of course have been in use in speech earlier, though they were never written. Considerable uncertainty surrounds the origin of some of them, and the question is complicated by the fact that at some date in or before the Ramesside Age the whole of the names seem to have been thrown one month back in the year.

The week of seven days was totally unknown to the early Egyptians and the evidence brought forward for its existence in very late times is far from convincing.

The day and the night were each divided into 12 hours, but as the day was measured sometimes from sunrise to sunset and sometimes from the appearance of daylight to its disappearance, the length of day and of night varied through the year. Consequently the Egyptians cannot claim to have established the hour as a fixed unit of time. (T. E. P.)

#### BABYLONIAN AND ASSYRIAN

**Babylonian, from 2000 B.C. Onwards.**—The Babylonian calendar imposed by the kings of the First Dynasty of Babylon, on all the cities immediately under their rule, was adopted by the Assyrians at the end of the second millennium B.C., was used by the Jews on their return from exile, and was widely used in the Christian era. This calendar was equated with the Sumerian calendar in use at Nippur at the time of the Third Dynasty of Ur (about 2300–2150 B.C.) in the following manner:

| Bab.   | Sum.              | Bab.       | Sum.            |
|--------|-------------------|------------|-----------------|
| Nisan  | = Bar. Zag. Ga.   | Tashritum  | = Du. Ku.       |
| Aiaru  | = Gud. Si. Di.    | Arakhsamna | = Apin. Du. A.  |
| Simanu | = Seg. Ga.        | Kislimu    | = Gan. Gan. Na. |
| Du'uzu | = Su. Numun. Na.  | Tebitum    | = Ab. Ba. E.    |
| Abu    | = Ne. Ne. Gar.    | Shabat     | = Aš. Am.       |
| Ululu  | = Kin. Innin. Na. | Addaru     | = Se. Gur. Kud. |

These were lunar months, and in general their length was 30 days; in historical times regular watch was kept for the new moon, and if that fell on the 30th of a month, then the day automatically became the first of the next month, and all officials were apprised of the fact. In order to prevent too serious a derangement of the seasons owing to the discrepancy between 12 lunar months and the solar year, a month was intercalated; the intercalary month might be a second Elul (Ululu) or a second Adar. Such intercalations were, in the late period, regularly devised within a cycle; in the Seleucid period and earlier, from 382 B.C., the cycle was 19 years, from 504–383 it was 27 years, from 528–505 it was eight years. Before the reign of Darius the intercalation was not based on any fixed cycle, but was inserted when the astronomers advised the king that it was necessary, the object being, it has been suggested, that the first of Nisan, with which the year always began, should not fall over a month later than the spring equinox, and not more than a month before it. It has been calculated that the actual variation in terms of the Julian calendar amounts to about 27 days. Nisan is therefore roughly March–April, but in certain extreme cases April–May.

The meanings of the names of the months cannot be ascertained with certainty. *Nisanu* seems to mean "sacrifice," *Aiaru* "blos-

som," *Simanu* "the fixed, appointed time," whether in relation to some ritual observance is not clear, *Du'uzu* is a form of Tammuz due to sound changes and the month was so named because vegetation had left the parched earth then, *Arakhsamna* is "the eighth" month. Since these names belong to the Akkadian language, it is probable that they arose in Babylonia, but it is conceivable that they were already known to the earliest people of Semitic speech before they entered the Euphrates valley.

The month was divided into unequal periods by days with special names, the first, *arhu*, the seventh, *sibutu*, the 15th, *šabattu*, the 28th, *bubbulu*, and the 3rd., 7th., 16th., *nubattu*, "rest"; but there was no system of continuous reckoning in weeks of seven or any other number of days. The day was divided into six watches, three for the day, three for the night, the first being called "sunrise," *napakh Shamshi*, "siesta," *mus-lahu*, and "sunset," *ereb Shamshi*, or "evening," *lilati*; the second "peeping (of the stars)," *bararitu*, "middle," *qablitu*, and "the time of dawn," *šat urri*. Time was reckoned in double hours, 12 to the day, and it is probable that the astronomers, if not all others, reckoned day as beginning with sunset. The hours consisted of 30 smaller divisions. Exact reckoning was secured by measuring weights of water passing through a pierced bowl—a water clock.

Other calendars were in use in the seventh century within the Assyrian empire. Thus a month Kanun, which was probably derived from a Syrian calendar, is testified to by a man's name. The Elamites had a calendar of their own occasionally used in Assyria.

**Early Assyrian, Before 1000 B.C.**—The calendar regularly used in Assyria before the tenth century, and even after that date occasionally, was not derived from Babylonia. The month names are: (1) Qarrate, (2) Tan(?)marte, (3) Sin, (4) Kuzalli, (5) Allanate, (6) Belti-ekallim, (7) Sarate, (8) Kinate, (9) Mukhur ili, (10) Ab sharrani (11) Khibur, (12) Sippim. These months are differently equated by cuneiform scribes with Babylonian months; one list makes Qarrate equivalent to Addaru, the other to Shabatu, i.e., either Feb.–March, or Jan.–Feb. The difference may perhaps have arisen from the lack of intercalation in the Assyrian calendar over a long space of time. It is to be noted that there is no certain occurrence of an intercalary month in this Assyrian calendar.

The meanings of the names are in this instance also known in a few cases. The first month derived its name from a festival in which the *limmu* or eponymous officer of the year took part, perhaps connected with the drawing of lots. The second, Tanmarte, if correctly read, is the month of "shining forth," the third is the month of the moon-god, the fourth perhaps "of gourds," the fifth, "of terebinths," the sixth is named after a form of Ishtar called "the Lady of the Palace," the ninth is named after a special offering made to gods when entering holy buildings. The origin of this calendar must lie in the times before the Assyrians entered the Tigris valley. It was not the Subaraean calendar, for the three known Subaraean month-names were *Ari*, and "the month of Adad" and "the month of Nergal." This Assyrian calendar was used over an extensive area at the time of the Third Dynasty of Ur, for it occurs on the tablets from Caesarea (Mazaca) at that time, together with other month names, Kiratim, "of gardens," Tinatim, "of figs," and Narmak-Ashur, "the libation of Ashur." This last month was the same as Kinatim, and was only temporarily used, the other two also may represent a change in nomenclature. But it had no currency in the middle Euphrates, for in the kingdom of Khana, immediately north of Babylonia, still another calendar was used, including the names Kinunu, "stove" (the later Kanun), Birissaru, Teritum, Belitbiri, "the lady of vision," Igi-kurra (a divine title); the order of these months is unknown, and it is uncertain whether this calendar was used outside Khana. Still other month names must have been used elsewhere, for on documents of the First Dynasty of Babylon there occur the names Tiru, Nabru, Sibutu, Rabutu (equivalent to Nisan), Mamitu, and Isin-Abi.

The most striking feature of the Assyrian calendar is its commencement, not at the spring equinox, but one or even two months before. This feature proves a complete independence of any astronomical observation when the calendar was first formed, but its

exact cause cannot be defined. The general meanings of the month-names, with the exception of the third and sixth, seem to show that this was an agricultural calendar, based simply on the farming year; the month names closely connected with ritual observances may have been adopted long after the origin of the actual calendar itself.

**Sumerian Calendars.**—The calendar used by the kings of the Third Dynasty of Ur (*see* above), and always subsequently kept as "ideograms" for the later month names, seems to have originated as the local calendar of the city of Nippur at a time when various other city-calendars were in use. The meanings of these month names may be roughly as follows: (1) "month of the dweller of the sanctuary," (2) "month of the leading out of the oxen," (3) "month of brick-making," (4) uncertain, (5) "month of setting the fire," (6) "month of a (certain) festival of Ishtar," (7) "month of the sacred place" *duku*, (8) "month of opening the irrigation canals," (9) "month of ploughing (?)," (10) named after a religious festival, (11) "month of emmer-grain," (12) "month of corn-harvest." An intercalary month DIR.ŠE.GUR.KUD. was inserted, but no fixed principle can be observed.

The Nippur calendar was not used at Lagash, Umma or the ancient town which occupied the site of the modern Duraïhim, under the Third Dynasty of Ur, *i.e.*, about 2300–2150 B.C. The month names at Lagash in use at the time of Sargon of Agade, *i.e.*, before 2500 B.C., number about 25, but not all these names belonged to a calendar; some are merely descriptions of a month as that in which sheep-shearing took place, or when men arrived from a certain place. The fixed month-names at Lagash, Umma, and Duraïhim, where two calendars were in use at the same time, for the Third Dynasty of Ur period were:—

| Lagash.   | Umma.   | Ur.   | Duraïhim.  |
|---|---|---|--|
| Gan. Maš.<br>Har. Ra. Ne.<br>Mu. Mu.<br>Ezen aNe. Šu.           | Še. Gur. Kud.<br>Sig. I. Šub.<br>Ba. Gar.<br>Še. Kar. Gal.<br>La. | Še. Gur. Kud.<br>(Dir. Še. Gur.<br>Kud.)<br>Maš. Ku. Ku.    | Maš. Du. Ku.<br>Šeš. Da. Ku.   |
| Šu. Kul.  | ..  | Šeš. Da. Ku.  | U. Ne. Ku  |
| Dim. Ku.  | ..  | U. Ne. Ku.  | Ki. Sig. Nin. A.<br>Zu.  |
| Ezen aDumu-<br>Zi.  | Šu. Numun.  | Ki. Sig. Nin. A.<br>Zu.                                     | Ezen. Nin. A.<br>Zu.   |
| Ezen aŠul. Gi.  | Min. Ab.  | Ezen. Nin. A.<br>Zu.  | A. Ki. Ti.   |
| Ezen aBa. U.<br>Mu. Su. Du.<br>Amar. A. A. Si.<br>Še. Gur. Kud. | E. Itu. Aš.<br>aNe. Gun.<br>Ezen. aŠul. Gi.<br>Kur. U. E.         | A. Ki. Ti.<br>Ezen aŠul. Gi.<br>Šu. Eš. Ša.<br>Ezen. aMakh. | Ezen aŠul.<br>Gi.<br>Šu. Ešh. Ša.<br>Ezen. Makh.<br>Ezen. An. Na.<br>Ezen. Me. Ki.<br>Gal. |
| (Dir. Še. Gur.<br>Kud.)<br>Še. Il. La.                          | aDumu-Zi.<br>(Dirig.)   | Ezen. An. Na.<br><br>Ezen. Me. Ki.<br>Gal.                  | Še. Gur. Kud.  |

Those names enclosed in brackets are the names of the intercalary months marking the position in the calendar when intercalated. All, or nearly all, these names are derived from specific festivals and ritual acts. The lists are sufficient to prove three points: (1) names were borrowed by one local calendar from another at this time, (2) the time of the festivals in the different cities must have varied, for it is inconceivable that the festival of Shulgi, the second king of the Third Dynasty of Ur, could ever have been in the same month at Umma and Lagash, (3) that the intercalation in different towns was independent. We are not in a position to explain the complicated calendar of this period by the position at an earlier date; the earliest month names, from the pre-Sargonic or early Sumerian period offer even greater difficulties, and are also connected with religious festivals and ritual acts. Of all the Sumerian calendars, that of Nippur, which is derived from agricultural habits, looks the most primitive, but the point must remain quite obscure. Some local Sumerian month-names survived until the period of the First Dynasty of Babylon, and the reduction of the confusion in this matter to comparative order was probably due to Hammurabi. (S. SM.)

## HINDU

From very early times Hindus have employed luni-solar cycles made by the combination of solar years and lunar years so treated as to keep the beginning of the lunar year near that of the solar year. The detailed arrangement of the earliest form of Hindu calendar is still a subject of research but, from about A.D. 400, under the influence of the Greek astronomy, developed the Hindu calendar as known to-day.

For civil purposes, solar years are used in Bengal, Orissa and in the Tamil and Malayālam districts of Madras; elsewhere lunar years. But everywhere the general religious rites and festivals are regulated by the lunar year and the details of private and domestic life (auspicious occasions for marriages, undertaking journeys, etc.), are based upon the lunar calendar. Even almanacs showing the solar year give details of the lunar year. The civil solar year is determined by the astronomical solar year, beginning with an artificial nominal equinox instead of with the true one.

**The Solar Month.**—The solar year is divided into 12 months, in accordance with the successive *saṃkrāntis* or entrances of the sun into the (sidereal) signs of the zodiac, which, as with us, are 12 in number. The names of the signs in Sanskrit are as follows: Mēsha, the ram (Aries); Vṛishabha, the bull (Taurus); Mithuna, the pair, the twins (Gemini); Karka, Karkāṭa, Karkāṭaka, the crab (Cancer); Simha, the lion (Leo); Kanyā, the maiden (Virgo); Tulā, the scales (Libra); Vṛiścika, the scorpion (Scorpio); Dhanus, the bow (Sagittarius); Makara, the sea-monster (Capricornus); Kumbha, the water-pot (Aquarius); and Mīna, the fishes (Pisces). The solar months are known in some parts by the names of the signs or by corrupted forms of them; and these are the best names for them for general use, because they lead to no confusion. But they have elsewhere another set of names, preserving the connection of them with the lunar months: the Sanskrit forms of these names are Chaitra, Vaiśākha, Jyāishṭha, Aśāḍha, Śrāvaṇa, Bhādrapada, Āśvina or Āsvayuja, Kārttika, Mārgaśīra or Mārgaśīrsha (also known as Agrahāyaṇa), Pausha, Māgha, and Phālguna: in some localities these names are used in corrupted forms, and in others vernacular names are substituted for some of them; and, while in some parts the name Chaitra is attached to the month Mēsha, in other parts it is attached to the month Mīna, and so on throughout the series in each case. The astronomical solar month runs from the moment of one *saṃkrānti* of the sun to the moment of the next *saṃkrānti*; and, as the signs of the Hindu zodiac are all of equal length, 30 degrees, as with us, while the speed of the sun (the motion of the earth in its orbit round the sun) varies according to the time of the year, the length of the month is variable: the shortest month is Dhanus; the longest is Mithuna.

**The Civil Day.**—The civil days of the solar month begin at sunrise. They are numbered 1, 2, 3, etc., in unbroken succession to the end of the month; the length of the month being variable, the number of civil days may range from 29 to 32.

The civil days are named after the weekdays, of which the usual appellations (there are various synonyms in each case, and some of the names are used in corrupted forms) are in Sanskrit Āditya-vāra or Ravivāra, the day of the sun, sometimes called Ādivāra, the beginning-day (Sunday); Sōmavāra, the day of the moon (Monday); Maṅgalavāra, the day of Mars (Tuesday); Budhavāra, the day of Mercury (Wednesday); Bṛihaspativāra or Guruvāra, the day of Jupiter (Thursday); Śukravāra, the day of Venus (Friday); and Śanivāra, the day of Saturn (Saturday). While some of the astronomical books perhaps postulate an earlier knowledge of the "lords of the days," and other writings indicate a still earlier use of the period of seven days, the first proved instance of the use of the name of a weekday is of the year A.D. 484, and is furnished by an inscription in the Saugor district, Central India.

The main divisions of the civil day are 60 *vipalas* = 1 *pala* = 24 seconds; 60 *palas* = 1 *ghaṭikā* = 24 minutes; 60 *ghaṭikās* = 24 hours = 1 day. There is also the *muhūrta* = 2 *ghaṭikās* = 48 minutes: this

is the nearest approach to the "hour." The comparative value of these measures of time may perhaps be best illustrated thus:  $2\frac{1}{2}$  *muhūrtas* = 2 hours;  $2\frac{1}{2}$  *ghaṭikās* = 1 hour;  $2\frac{1}{2}$  *palas* = 1 minute;  $2\frac{1}{2}$  *vipalas* = 1 second.

As their civil day begins at sunrise, the Hindus naturally count all their times, in *ghaṭikās* and *palas*, from that moment. But the moment is a varying one, though less in India than in European latitudes; and Hindus have recognized the necessity, in connection with their lunar calendar, of a convenient means of referring their own times to the time which prevails officially. Consequently, many almanacs have adopted the European practice of showing the time of sunrise, in hours and minutes, from midnight; and some of them add the time of sunset from noon.

The lunar year consists primarily of 12 lunations or lunar months, of which the present Sanskrit names, generally used in more or less corrupted forms, are Chaitra, Vaiśākha, etc., to Phālguna, as given above in connection with the solar months. It is of two principal varieties, according as it begins with a certain day in the month Chaitra, or with the corresponding day in Kārttika: the former variety is conveniently known as the Chaitrādi year; the latter as the Kārttikādi year. For religious purposes the lunar year begins with its first lunar day: for civil purposes it begins with its first civil day, the relation of which to the lunar day will be explained below. Owing to the manner in which the beginning of the lunar year is always shifting backwards and forwards, it is not practicable to lay down any close equivalents for comparison: but an indication may be given as follows. The first civil day of the Chaitrādi year is the day after the new-moon conjunction which occurs next after the entrance of the sun into Mīna, and it now falls from about March 13 to about April 11; the first civil day of the Kārttikādi year is the first day after the new-moon conjunction which occurs next after the entrance of the sun into Tulā, and it now falls from about Oct. 17 to about Nov. 15.

The present names of the lunar months, indicated above, were derived from the *nakshatras*, which are certain conspicuous stars and groups of stars lying more or less along the neighbourhood of the ecliptic. The *nakshatras* are regarded sometimes as 27 in number, sometimes as 28, and are grouped in 12 sets of two or three each, beginning, according to the earlier arrangement of the list, with the pair Kṛttikā and Rōhiṇī, and including in the sixth place Chitrā and Svāti, and ending with the triplet Rēvatī, Aśvinī and Bharaṇī. They are sometimes styled lunar mansions, and are sometimes spoken of as the signs of the lunar zodiac; and it is, no doubt, chiefly in connection with the moon that they are now taken into consideration. But they mark divisions of the ecliptic: according to one system, 27 divisions, each of 13 degrees 20 minutes; according to two other systems, 27 or 28 unequal divisions, which we need not explain here. The almanacs show the course of the sun through them, as well as the course of the moon; and the course of the sun was marked by them only, before the time when the Hindus began to use the 12 signs of the solar zodiac. So there is nothing exclusively lunar about them. The present names of the lunar months were derived from the *nakshatras* in the following manner: the full-moon which occurred when the moon was in conjunction with Chitrā (the star α Virginis) was named Chaitrī, and the lunar month, which contained the Chaitrī full-moon, was named Chaitra; and so on with the others. The present names have superseded another set of names which were at one time in use concurrently with them; these other names are Madhu (= Chaitra), Mādhava, Sukra, Suchi, Nabhas, Nabhasya, Isha, Ūrja (= Kārttika), Sahas, Sahasya, Tapas, and Tapasya (= Phālguna): they seem to have marked originally solar season-months of the solar year, rather than lunar months of the lunar year.

A lunar month may be regarded as ending either with the new-moon, which is called *amāvāsyā*, or with the full-moon, which is called *pūrṇamāsī*, *pūrṇimā*: a month of the former kind is termed *amānta*, "ending with the new-moon," or *suklādi*, "beginning with the bright fortnight"; a month of the latter kind is termed *pūrṇimānta*, "ending with the full-moon," or *kṛishṇādi*, "beginning with the dark fortnight." For all purposes of the calendar, the *amānta* month is used in Southern India, and the *pūrṇimānta* month in

Northern India. But only the *amānta* month, the period of the synodic revolution of the moon, is recognized in Hindu astronomy, and for the purpose of naming the lunations and adjusting the lunar to the solar year by the intercalation and suppression of lunar months; and the rule is that the lunar Chaitra is the *amānta* or synodic month at the first moment of which the sun is in the sign Mīna, and in the course of which the sun enters Mēsha: the other months follow in the same way; and the lunar Kārttika is the *amānta* month at the first moment of which the sun is in Tulā, and in the course of which the sun enters Vṛiśchika. The connection between the lunar and the solar months is maintained by the point that the name Chaitra is applied according to one practice to the solar Mīna, in which the lunar Chaitra begins, and according to another practice to the solar Mēsha, in which the lunar Chaitra ends. Like the lunar year, the lunar month begins for religious purposes with its first lunar day, and for civil purposes with its first civil day.

One mean lunar year of 12 lunations measures very nearly 354 days 8 hrs. 48 min. 34 sec.; and one Hindu solar year measures 365 days 6 hrs. 12 min. 30 sec. according to Āryabhaṭa, or slightly more according to the other two authorities. (See CHRONOLOGY: *Hindu*.) (X.)

### GREEK

(1) **General.**—The Greek calendar, even in its most developed forms, differed from all modern European systems in being *solilunar*; *i.e.*, in theory, every year began when the sun was in a certain position (solstice or equinox) and every month began with the new moon. But, as the solar year (solstice to solstice or equinox to equinox) is not even approximately divisible by the lunar month, the result was that some system of adjustment was necessary. This was found, at an uncertain but early date, in the *oktaeteris* or eight-year group. Eight solar years are  $8 \times 365.25$  days, roughly, *i.e.*, 2,922 days. Eight lunar years, *i.e.*, eight groups of twelve lunar months each, are  $8 \times 12 \times 29.50$  days approximately, *i.e.*, 2,832 days. The difference, 90 days, is about three lunar months. Hence, by inserting, at different times within the *oktaeteris*, three extra months, approximate agreement with natural phenomena was obtained. But it was at best only approximate, for the above lengths of a solar year and a lunar month are not exact (see ASTRONOMY), and to bring the calendar into accuracy would have meant abandoning the principle of beginning each month at new moon; but this principle was sacred, and could not be abandoned, at least in theory. An important attempt at reform was made by the astronomer Meton of Athens. By his system, the years, commencing from the end of June, 432 B.C. of our reckoning, were grouped into "great years" of 19 each, with seven intercalary months. This gave, on an average, a month of 29 days, 12 hr., 45 min., 57 sec.—less than 2 minutes too long. Callippus of Cyzicus later combined four Metonic cycles into one, and finally Hipparchus of Nicaea combined four Callippian periods into one cycle of 304 years, by which a very high degree of accuracy was obtainable. These theoretical constructions, however, affected the official years little, if at all, and intercalation went on in a very lax and unscientific fashion, resulting in civic calendars which were often some months out.

The month was not divided into weeks; the planetary week is astrological, connected with the dogma that every period of time, including the day, had a planet for its regent. It is not much older than the Christian era, and was never official in classical times (see F. H. Colson, *The Week*, 1926). There was, however, a division into thirds. The first ten days of the month were called *μην ἱστάμενος* or commencing month; the last third, *μην φθίνων*, or waning month; for the middle third, no regular term was in use. Days of a higher number than 20 were either called the first, second, etc., after the *eikades* (twenties), or numbered backwards; thus at Athens, *Βοηδρομιῶνος ἑκτη φθίνοντος* meant the sixth day, counting inclusively, from the *end* of the month Boedromion. The day was officially computed from sunset to sunset; practically it began at dawn.

Parallel with all this reckoning there ran the farmers' and sailors' calendars, based on observation of the heliacal rising and

setting of the constellations (such-and-such work was to be done when the Pleiads rose, navigation was not safe after the setting of Arcturus, etc.), or on such phenomena as the appearance of various flowers, migratory birds, and the like. Many private persons had calendars (*parapegmata*), on which, by moving a peg from one hole to another, it was possible to see the relative positions of the civil and natural years.

(2) **Individual Calendars.**—That of Athens is the best known. It began, or was supposed to begin, at the summer solstice, or rather at the new moon next to that; hence about the end of June. The months were called *Hekatombaion*, *Metageitnion*, *Boedromion*, *Pyanopsion* (later *Pyaneption*), *Maimakterion*, *Poseideon*, *Gamelion*, *Anthesterion*, *Elaphebolion*, *Mounichion*, *Thargelion*, and *Skirophorion*. When intercalation was necessary, the month *Poseideon* was repeated; the intercalary month was then called *Second Poseideon*. The first day of each month was called *ἑνὴ καὶ νέα*, i.e., old and new; for as the month began officially at sunset, but most people reckoned the day from dawn (see above), the day of new moon fell between two months. Every month was either "full" (*πλήρης*), consisting of 30 days, or "hollow" (*κοῖλος*), with 29 days.

It is clear that the months are mostly named after gods (as *Poseideon*, cp. the Delian *Artemision*, the Delphic *Heraios*, and the Boeotian *Hermaios*) or after festivals (as *Anthesterion*, cf. *Pamboiotios* in Boeotia, *Karneios* in Laconia). This accords with the probable history of the calendar. It began, not as a scheme of continuous reckoning, but as a series of notable days or groups of days (*ἑορταί*, *ἱερομνηταί*), corresponding in some cases at least to seasonal events, such as harvest. The days between these, unless they were days of new moon, or full moon, were not holy, and therefore not reckoned. The Boeotian year began with the winter solstice, the Laconian with the autumn equinox. In some of the later calendars, as those of Achaia and Phocis, the months were not named, but only numbered.

In Hellenistic times, more and more use was made of the official Egyptian year, which was in use under the Ptolemies. It consisted of 365 days, without intercalation, with the result that every four years it lost a day, and in 1,461 years it came right again. The months were called Thoth, Phaophi, Athyr, Choiak, Tybi, Mechir, Phamenoth, Pharmouthi, Pachon, Pauti, Epiphi and Mesori.

See A. Mommsen, *Das Kalenderwesen der Griechen* (1883); G. F. Unger in I. von Müller's *Handbuch* (1886); Schmidt and Rühl, *Handbuch der Griech. Chronologie* (1888); and J. Gow in Whibley's *Companion to Greek Studies* (1916).

In 26 B.C., when Augustus reformed the Egyptian calendar to bring it into line with the Julian, Thoth 1 was equivalent to Aug. 29. This reformed Egyptian calendar had a long struggle to come into actual use, however. Also important for late times is the native Macedonian calendar, originally twelve lunar months called Dios, Apellaios, Audynaioi, Peritios, Dystros, Xanthikos, Artemisios, Daisios, Panemos, Loios, Gorpiaios, Hyerberetaios. About the beginning of our era this calendar, which was in common use in Asia Minor and Syria, was reformed on Julian lines.

Ideler, *Handbuch d. mathematischen u. technischen Chronologie* (Berlin, 1825) is still valuable. Good outline by G. F. Unger, *Zeitrechnung d. Griechen u. Römer*, in i. v. Müller's *Handbuch*, i., p. 711 ff. To his bibliography add: M. P. Nilsson, *Primitive Time-Reckoning* (Lund and Oxford, 1920); *Die Entstehung u. religiöse Bedeutung des gr. Kalenders*, in *Lunds Universitets Årsskrift*, N.F., Avd. 1, Bd. 14, Nr. 21 (Lund and Leipzig, 1918); J. K. Fotheringham in *Journ. Hell. Stud.*, xxxix. (1919), p. 164 foll.

## ROMAN

The Roman Republican calendar was of the Greek type (see above), but rude and primitive, dating probably from the times of the Etruscan dynasty, but showing traces of a still earlier period. It consisted of twelve lunar months, *Martius*, *Aprilis*, *Maius*, *Iunius*, *Quintilis*, *Sextilis*, *September*, *October*, *November*, *December*, *Ianuarius*, *Februarius*. Of these, *Martius*, *Maius*, *Quintilis* and *October* had each 31 days, the rest 29, save *Februarius*, which had 28. The ancients attributed this to Numa, and a good tradition, unjustly suspected in ancient and modern times, de-

clares that *Ianuarius* and *Februarius* were additions to an original year of 10 months. Such a year of course was discontinuous; between year and year there was a gap of some 60 days, a phenomenon quite well authenticated among savage and barbarous people. There was a dead season in winter; as this is better fitted to central European than to Italian climatic conditions, it seems likely that this very ancient calendar was brought by northern invaders. February was popularly thought to end, however, on the 23d, the *Terminalia*, and it was after this date that intercalation was made, which took place once or twice in four years. The *mensis intercalaris* or *Mercedonius* was followed by the remaining five days of February; the recently discovered *Fasti Antiates* (pre-Julian) show this system in use. In 153 B.C. Jan. 1 ousted Mar. 1 as the official New Year's day.

The working of the calendar was in the hands of the *pontifices*, who every month used to watch for the new moon, and, when it was seen, proclaimed from the Capitol the number of days, five or seven, to the Nones. Thus the first day of the month was called *kalendae*, or callings. Full moon was called the Ides (*idus*); this, in the four long months, was the 15th, in the others the thirteenth. The Nones (*nonae*), were the ninth day, by inclusive reckoning, before the Ides, i.e., the 5th or 7th respectively. Other days were reckoned as so many before the Kalends, Ides, or Nones, e.g., *a(nte) d(iem) iii non(as) Quint(iles)*, the 3rd day before the Nones of *Quintilis*=July 5. The 2nd, 6th (or 8th), and 14th (or 16th) were often called *postridie kalendas, nonas, idus*, i.e., the day after the Kalends, etc. They were all, especially the day after the Kalends, unlucky (*dies postriduanus*). The Ides were sacred to Jupiter; on the Kalends, sacrifice was offered to Juno and also to Janus; the Nones were sometimes a day of festival.

**Eight-day Weeks.**—Independent of the months were the eight-day "weeks" called *nundinae*; these had no individual names, were not closely connected with any religious practices of importance, and were simply the space from one market-day to another. They are marked on the surviving calendars with the letters A-H. The *dies Aegyptiaci* marked on some later calendars have no significance for Roman cult, but are astrological. Festivals were almost without exception on the odd-numbered days; if a festival lasted more than one day, there were breaks of one or three days in between, as *Lucaria*, *Quintilis* 19 and 21; *Carmentalia*, Jan. 11 and 15. Some months clearly arose out of seasons of ritual; thus *Martius* contains several important festivals connected with Mars, *Februarius* is the month of purifications (*februa*).

Owing to the clumsiness of the *pontifices*, and still more to political manoeuvres, by which intercalation was made or omitted recklessly to affect a magistrate's year of office, the calendar got into hopeless confusion by the end of the republic, and Julius Caesar undertook its reformation. In 46 B.C. he intercalated, and furthermore added 67 days between November and December, making a year of 445 days, and so bringing the civil abreast of the natural year. Then began the new, Julian calendar, which, with small modifications, lasted until the Gregorian reform. Its months were those still in use; intercalation was made, by repeating Feb. 23 (*a.d.vi.kal.Mart.*, hence the name bissextile for a leap-year). The months *Quintilis* and *Sextilis* were renamed later, after *Iulius* and *Augustus* and, in spite of several strenuous efforts of the authorities, other attempts to give a month the name of an emperor were of no permanent effect.

Much of our information comes from inscriptions which set out the whole calendar, with a sign against each day indicating whether it is *F(as)*, or available for legal business, *N(efas)*, or not so available, *C(omitatus)*, or available for a meeting of the Assembly, *NP* (*nefas, feriae publicae*), or a feastday, or *END* (*otercisus*), i.e., *nefas* morning and evening, *fas* in the middle. Certain other signs refer to special days, as *Q(uando) ST(ercus) D(elatum) F(as)* (June 15, cleansing of shrine of Vesta), *Q(uando) R(ex) C(omitavit) F(as)*, March 24.

The classical work is Mommsen, *Römische Chronologie*; to the literature given by Unger, add M. P. Nilsson, in *Strena Philologica Vpsaliensis* (1922); H. J. Rose, *Primitive Culture in Italy* (1925). (H. J. R.)

## JEWISH

The Jewish Calendar in use to-day is both solar and lunar, the years being reckoned by the sun and the months by the moon. In order to adjust the two systems a month is intercalated in the 3rd, 6th, 8th, 11th, 14th, 17th, and 19th years of a 19-year cycle. For practical purposes, such as the beginning of Sabbath, the day begins at sunset but the calendar day of 24 hours, always begins at 6 p.m. The hour is divided into 1,080 parts (*Ḥalaqim*) each part (*Ḥēlaq*) being equal to 3.3 sec. The *Ḥēlaq* is sometimes further divided into 76 *rega'im*. A synodical month is the interval between two conjunctions (Conjunction = *Molad*) and amounts to 29 days 12 hours 44 min.  $3\frac{1}{3}$  sec. The calendar month must, however, naturally contain an exact number of days, consequently the Hebrew month varies between 29 and 30 days, no month has either 28 or 31. The full (*Mālē*) month contains 30 and the defective (*Ḥāšēr*) 29 days. The months *Niṣṣan*, *Šivan*, *Ab*, *Tishri*, and *Shebat* are always full; *Iyyār*, *Tammūz*, *Ellūl*, *Tēbēth* and *Adar* are always defective, while *Marḥeshvān* and *Kislev* may vary.

The number of days in a year naturally changes. The total will be the days in month (29d. 12 h. 44 min.  $3\frac{1}{3}$  sec.) multiplied by 12 in an ordinary year and by 13 in a leap year. But as either process would result in a fractional answer, the ordinary year has 353, 354 or 355 days and the leap year 383, 384 or 385. The New Year begins on *Tishri* 1, but it may be delayed by one or two days for various reasons. Thus, in order to prevent the Day of Atonement (*Tishri* 10) from falling on a Friday or Sunday, the New Year must avoid Sunday, Wednesday or Friday. Or again, if the conjunction of *Tishri* takes place after noon, so that the crescent would not be seen on that evening, the New Year is one, or sometimes two days later. Other causes may also produce delays (*dehiyyōth*). A year in which *Marḥeshvān* and *Kislev* are both full, is called complete (*Shelemāh*), and will contain 355 or 385 (if leap) days. In a normal (*Ke-Sidrāh*) year, in which the former month is defective and the latter full, the total of days will be 354 or 384, while in a defective (*Ḥaserāh*) year, when both months contain only 29 days each, the total of days will be 353 or 383. The character of a year (*qebīac*, lit. "fixing") is described by a group of three Hebrew consonants, the first and third giving the days and the week on which New Year and Passover fall respectively, while the middle consonant is the initial of "normal," "defective" or "complete." There can be only 14 types of *qebī'ōth*, seven in common and seven in leap years.

The mean beginning of the four seasons is called *Tequfāh* (lit. orbit or course), spring beginning when the sun reaches the equinoctial point in *Niṣṣan*, summer in *Tammūz*, autumn in *Tishri* and winter in *Tēbēth*. The length of the seasons was variously fixed by different Rabbis. In the 3rd century A.D. Mar Samuel *Yarḥinai* (165-250, head of Academy of Nehardea) calculated the interval between *tequfōth* as 91 days, 7 hours, 30 min. It was observed that the first *tequfāh* always moves forward, year after year, by one day and six hours. The result is that after 28 years have elapsed the *Tequfāh* reverts to the same day and to the same time of day as at the beginning. This orbit is called the Great or Solar Cycle (*Mahzor Gadōl* or *Hamāh*). Samuel's length of the solar year (365 $\frac{1}{4}$  days) was emended by R. Adda to 365 days, 5 hours, 55 min., 25 $\frac{2}{5}$  sec., a total approximating to the Ptolemaic year, but still too great by nearly seven minutes.

In addition to the solar cycle of 28 years, the Jewish Calendar employs, as mentioned above, a smaller or lunar cycle (*Mahzōr qatān*) of 19 years in order to adjust the lunar months to the solar year by means of intercalations. The Feast of Passover, on 14 *Niṣṣan* could not begin before the spring *Tequfāh* and therefore the intercalary month finally selected was *Adar*. A regular intercalation was not practised before the introduction of the continuous calendar and the adoption of the Metonic cycle. The *Mahzōr qatān* is based on the equation  $\frac{235}{19} = 12 \times 7$ , for 235 lunar months correspond to 19 solar years. In order, therefore, to keep 12 months in the year, seven intercalations are necessary: the periodicity of these additions has been given above. The era which is in use to-day is that of the Creation (*Anno Mundi*, *Li-yetzirāh*, see CHRONOLOGY).

The present year of the Jewish Calendar, the year 5689 A.M., began on Sept. 15, 1928, and ends on Oct. 4, 1929. It was known as 689 according to the short system (*i.e.*, omitting the thousands); it was a leap year containing 13 months, 55 Sabbaths and 385 days. The *qebī'a* was *Zayin*, *Shin*, *hē*, which indicates that New Year fell on the 7th (*Zayin*) and Passover on the 5th (*hē*) day of the week and that *Marḥeshvān* and *Kislev* each contained 30 days (complete, *shelemāh*, *shin*). 5689 was the 8th year of the 300th lunar cycle since the Creation and the 5th of the 204th of the solar cycle since the Creation.

**Months and Important Days.**—The following list enumerates the months and the chief days in each:

*Tishri*: 1 and 2, New Year; 3, Fast of Gedaliah (II Ki. xxv. 22-5; Zech. xiii. 19); 10, Day of Atonement; 15-21, Tabernacles; 22, Eighth day of Solemn Assembly; 23, Rejoicing of the Law.

*Marḥeshvān*: 22, 25 and 29, First Monday, Thursday and Second Monday, Fasts (in 1928).

*Kislev*: 25, *Hanucah* (Feast of Dedication) begins.

*Tēbēth* 2, *Hanucah* ends; 10, Fast of *Tēbēth* (II Ki. xxv. 1; Zech. viii. 19).

*Shebat*: 15, New Year of Trees.

*Adar*: 13, Fast of Esther; 14-15, Purim.

(*We-Adar*; Second *Adar*, intercalated month).

*Niṣṣan*: 15-22, Passover.

*Iyyār*: 10, 13, 17, First Monday, Thursday and Second Monday, Fasts (in 1928).

*Šivan*: 6, 7, Pentecost.

*Tammūz* 17, Fast (Zech. viii. 19).

*Ab*: 9, Fast (II Ki. xxv. 8, and Zech. viii. 19).

*Ellūl*.

**Origin.**—The Jewish Calendar is the result of long development; the present form is not of great antiquity. The ancient Hebrew names of the months disappeared in the Exile and were replaced by Babylonian names (given above); but even before the Exile the months were more commonly designated by numbers. The Bible records only four names, *Abib* (1st), *Ziv* (2), *Ethanim* (7), and *Bul* (8); and the Gezer calendar tablet, which belongs to the period of the Jewish monarchy, employs purely agricultural designations and avoids names. Until quite late times the influence of the crops on the fixation of the calendar was powerful. In Babylon the Jews adopted the Babylonian names, seven of which (*Niṣṣan*, *Šivan*, *Tēbēth*, *Ellūl*, *Kislev*, *Shebat*, *Adar*) occur in Nehemiah and Esther, while six, *Tammūz*, *Ab*, *Ellūl*, *Tishri* and *Shebat* are mentioned in the Assouan Papyri (5th century B.C.). Though the habit of enumerating months continued, by the first century A.D. the complete 12 names are found in a list given in the Roll of Fasting (*Megillath Ta'anith*).

The Mishnah already knows of casual intercalations and in Nedarim viii. 5, the second *Adar* is mentioned as the month to be added. The Jews did not, however, derive the cycle of 19 years from the Babylonians, who did not possess a system of intercalation. The dates in the Assouan Papyri, and Talmudic evidence, make it clear that Jewish intercalation was empirical and irregular. In the beginning of the 2nd century Aqiba reckoned three successive years as intercalary.

The calendar was originally fixed by observation, and ultimately by calculation. Up to the fall of the Temple (A.D. 70), witnesses who saw the new moon came forward and were strictly examined and if their evidence was accepted the month was fixed by the priests. Eventually the authority passed to the Sanhedrin and ultimately to the Patriarch. When necessary, a second *Adar* was inserted in order that the reaping of the corn should come at Passover. Gradually observation gave place to calculation. The right to determine the calendar was reserved to the Patriarchate; the Jews of Mesopotamia tried in vain to establish their own calendar but the prerogative of Palestine was zealously defended. So long as Palestine remained a religious centre, it was naturally to the homeland that the Diaspora looked for its calendar. Uniformity was essential, for if different parts had celebrated feasts on different days confusion would have ensued. It was not until the 4th century A.D. that Babylon fixed the Calendar.

The Book of Jubilees, written in the 2nd century B.C., contains

a peculiar calendar, evidently based on a desire to reckon time in a distinctively Jewish way. Every event from the Creation to the beginning of the Exodus is dated in Jubilee periods of 49 years and in the heptads. The author uses a solar year of 364 days, or 52 weeks, divided into four quarters of 13 weeks. The calendar has been well described by Moore as a reaction against Hellenism. That it ever was used is more than doubtful.

The Qaraites (*q.v.*) opposed the Rabbanites on no point more vehemently than on the calendar; they regarded calculations as impious and useless and sought to reintroduce observation. In this matter they were victorious over the Great Rabbanite champion Ša'adya (892-942), whose theory that calculation preceded observation they could easily disprove. By the end of the 15th century necessity forced the Qaraites to adopt calculation. Ša'adya was more successful in his defence of the Jewish Exilarch against Ben Meir who, in 921, initiated a great controversy on the calendar. Ben Meir claimed to be a descendant of the Patriarchs, and hence asserted his right to fix the calendar. His main point was that New Year is not to be deferred unless the *Molad* takes place  $\frac{642}{1,080}$  of an hour after midday.

The Talmud speaks of various New Year's days. It may be regarded as certain that in Palestine the New Year began in *Nissan* (*cf.* Exod. xii. 2) and in Babylonia in *Tishri*.

For roughly turning years *Anno Mundi* to *Anno Domini*, the number 240 should be added and the thousands neglected. Thus (5) 689 A.M. = (1) A.D. 929. Conversely, (1) 929-240 = (5) 689. Since the Jewish year begins about September, consequently between September and December 31st, a difference of one may have to be adjusted. For more exact work by far the best tables are those of Schramm (*Kalendariographische Tafeln*, Leipzig, 1908).

See the articles and bibliographies in the *Jewish Encyclopaedia* and in Hastings *Encycl. of Religion and Ethics*. For the Calendar in the Book of Jubilees *cf.* G. F. Moore, *Judaism*, vol. i., pp. 193 seq. (1927). (H. M. J. L.)

# MAYA AND MEXICAN MAYA CALENDAR

As this was the basis of the Mexican and allied calendars, it is here treated first. It appears at first sight very complex, but is fairly simple and is admirable from its symmetrical completeness.

Every Maya date is expressed by two numbers and two names, forming a group of four; *e.g.*, 4 Ahau 8 Cumhu, or 9 Imix 19 Zip. This statement is similar to such a European date as Wed., Aug. 24, the 4 Ahau or 9 Imix being parallel to the Wednesday, as it gives the position in a gigantic week of 260 days, while the 8 Cumhu or 19 Zip is parallel to Aug. 24. But while in the European calendar Aug. 24 will fall on a Wednesday four times in 28 years and at unequal intervals therein, the Maya 4 Ahau or 9 Imix will not again occur on 8 Cumhu or 19 Zip until after the lapse of 52 years exactly, so there is no ambiguity. This period of 52 years is called the calendar round.

The Maya had a year of 365 days which was invariable, there being no leap year. This was divided into 18 months of 20 days each, together with five supplementary days at the end. The month names are, Pop, Uo, Zip, Zota, Tzec, Xul, Yaxkin, Mol, Chen, Yax, Zac, Ceh, Mac, Kankin, Muan, Pax, Kayab, Cumhu, together with the supplementary days, Uayeb. Within the month the days are numbered from 0 to 19 inclusive, instead of from 1 to 20, and similarly with Uayeb. Hence 8 Cumhu is what European usage would call the 9th of Cumhu. They also had a series of day names commencing with Imix as in the following table, the order of reading being down each column:

|          |       |       |       | Falls in month<br>on the days |    |    |    |
|----------|-------|-------|-------|-------------------------------|----|----|----|
| Imix     | Cimi  | Chuen | Cib   | 4                             | 9  | 14 | 19 |
| Ik       | Manik | Eb    | Caban | 5                             | 10 | 15 | 0  |
| Akbal    | Lamat | Ben   | Eznab | 1                             | 6  | 11 | 16 |
| Kan      | Muluc | Ix    | Cauac | 2                             | 7  | 12 | 17 |
| Chicchan | Oc    | Men   | Ahau  | 3                             | 8  | 13 | 18 |

This series of day names, like the European week, ran on continuously through the months and years without any interrup-

tion. But as there were 20 days in the month it followed that if any day name, such as Akbal, fell on the day 1 in the first month of any year, it must fall on the day 1 of each month throughout that year, and also on 1 Uayeb. But the five days of Uayeb would use up five of the 20 names, so that in the next year the day 1 of each month would have the day name Lamat, in the year after it would have Ben, in the next year Eznab, and in the

BY COURTESY OF DR. A. P. MAUDSLAY

STELA K. AT QUIRIGUA, GUATEMALA. OF THE "GREAT PERIOD" OF THE MAYA OLD EMPIRE. IT SHOWS DATE WITH "NORMAL" NUMERALS. next year Akbal again, the day name returning to the same month-day every four years. Hence each day name has only four possible month-days to fall on, as in above table. The Maya also had a series of 13 day numbers from 1 to 13 inclusive. These also formed a continuous series like our weeks and ran on uninterruptedly throughout the years and months. But each year contained 28 of these 13-day periods and one day more, so that the year ended with the same day number with which it began, and therefore the next year began with the next day number. Hence each month-day would each year have a day number one larger than in the year before, until the 13 numbers were exhausted, and the same day number returned. Combining this with the five-day progression of the day names, it results that only after 52 years (4 times 13) will the same day number and day name fall upon the same day of the same month. Again, as 20 and 13 have no common measure it follows that a day name will only have the same day number once in 260 days. This 260-day period commencing with 1 Imix is called the *Tonalamatl*, which was the Aztec name for it. The Maya name is unknown. It was of great importance for ceremonial and magical purposes.

**The Calendar Considered Astronomically.**—The Maya calendar forms a remarkably perfect instrument for reckoning time, as the various rules check each other like bookkeeping by double entry. This enables Americanists now to decipher partly obliterated inscriptions, and it directed the attention of the Maya

to precision in time reckoning. Thereby they had the first requisite of science, namely accurate measurement, and their attainments in astronomy were surprising. The year of 365 days, being nearly six hours shorter than the true tropical year, caused a Pop gradually to fall earlier in the true year at the rate of nearly a day every four years, and after 1,508 years the Maya year and the true year would again coincide. There is some evidence that the Maya allowed for this error, not by intercalating a day, which would upset their whole elaborate system, but by calculating the error from time to time and altering the dates for their festivals or agricultural operations accordingly, but not disturbing the order of months and days in the calendar. Taking an imaginary example, let us assume that certain agricultural operations and the festivals connected with them were at one time performed in Yaxkin. Then after 80 years the shift of the calendar would make the same date in the true year fall 20 days later in the Maya year, namely in Mol. Apparently then they performed the work in Mol instead of Yaxkin, and got right with the seasons without disturbing the calendar.

Probably the rising and setting of the sun over fixed landmarks was observed in order to correct the calendar, a method which would give the true length of the tropical year. In this connection the traditions of the Toltec and the Cakchiquel are instructive regarding the "sun" which their ancestors awaited, which was probably an observation of the sun by this method to correct the shifting calendar. The Cakchiquel annals mention the different places where each tribe saw its "sun," and as to one tribe it is said they had not finished drawing their lines when the sun appeared. It is also instructive to note that the Cakchiquel did not look for their "sun" until they arrived in or near the region where they were found at the Spanish conquest. It would seem then that having reached a new country they had to lay down lines of sight by which to observe sunrise or sunset, somewhat as the captain of a ship corrects his chronometer by observation of a known point of land.

The Dresden Codex shows that the Maya calculated the synodic period of Venus at 584 days, a good approximation, and divided this into four parts corresponding to the invisibility at inferior conjunction, visibility as morning star, invisibility at superior conjunction, and visibility as evening star. Dr. John E. Teeple makes it probable that they recognized the small error of this Venus table and applied a correction to it. The Dresden Codex also shows that they had made a close approximation to the true length of the lunar month. This lunar table was used for calculating eclipses. The synodic period of Mars was calculated and probably that of Jupiter, Saturn and Mercury are doubtful. Teeple shows that the supplementary series in the inscriptions contain a lunar count. A supplementary series only occurs in connection with an initial series (*see* CHRONOLOGY), though not all initial series have them. They show the length of the lunar month, that is whether it is of 29 or 30 days, the number of days elapsed of the lunar month, and the number of the lunar month in a series of five or six lunar months. Attempts have been made to correlate this with the sets of five and six lunar months into which the Dresden Codex eclipse table is divided, but so far this has not worked out satisfactorily in all cases.

STELA D. AT QUIRIGUA, GUATEMALA, OF THE "GREAT PERIOD" OF THE MAYA OLD EMPIRE. IT BEARS DATE WITH FULL-FIGURE NUMERALS

**The New Empire Calendar.**—The Maya who inhabited Yucatan at the coming of the Spaniards in the 16th century are spoken of as belonging to the new empire, as distinguished from those of the old empire, known only by their inscriptions in Guatemala and elsewhere and by the Dresden and two other hieroglyphic codices. The Books of Chilán Balam, written in Maya with Roman letters after the conquest, show the new empire method. The

THE SO-CALLED CALENDAR-STONE OF MEXICO, AZTEC PERIOD. IT SHOWS THE TWENTY DAY SIGNS IN INNER CIRCLE AND MAY RECORD CERTAIN IMPORTANT DATES IN MYTHOLOGICAL HISTORY

calendar was identical with that of the old empire except that the day names fell each one day earlier in the month. Thus Ahau fell on the month-day 2 instead of 3, etc. The reason for this is unknown. The new empire was much influenced by Nahua invaders from Mexico and this led to the use of the characteristic Nahua "Year-bearer," which is the day number and day name falling on 1 Pop and was used to name the year. Thus "the year-bearer was on 4 Kan" means that in that year 4 Kan fell upon 1 Pop. But the old calendar round method was still used, the year-bearer being sometimes given also. This is redundant since the year-bearer can be calculated from the calendar round date. But it had a practical use when the year-bearer alone was given, as it showed the year in which an event occurred without specifying the day. The old empire Maya seem, as far as our knowledge goes, to have had no way of doing this.

**Quiché and Cakchiquel Calendar.**—The Quiché and Cakchiquel of Guatemala had a similar system of day names and day numbers. The day names are: Imox, Igh, Akbal, Kat, Can, Camey, Quieh, Ganel, Toh, Tzii, Batz, Balam, Ah, Itz, Tziquin, Ahmak, Noh, Tihax, Caok, Hunahpu. Igh fell on the month-day 1, and so on. There were also 18 months of 20 days each and 5 supplementary days. The Cakchiquel names are: Tacaxepual, Nabey Tumuzuz, Rucab Tumuzuz, Zibix, Uchum, Nabey Mam, Rucab Mam, Likinka, Nabey Tok, Rucab Tok, Nabey Pach, Rucab Pach, Tziquin Kih, Cakan, Ibota, Katik, Itzcal Kih, Pariche and the supplementary days, Tzapi Kih. But the Cakchiquel only used the months for magical and ceremonial purposes, never for dating, neither did they use year-bearers. As they only cited the day number and day name in giving a date, e.g., 10 Caok, and as such a date will recur every 260 days, their dates were fixed by giving also the position in their era, for which *see* CHRONOLOGY.

#### MEXICAN CALENDAR

The Aztec system is the same as the Maya, but the names and glyphs are different. The day names are:—

|             |            |            |               | Falls in month<br>on the days |    |    |    |
|-------------|------------|------------|---------------|-------------------------------|----|----|----|
| Cipactli    | Miquiztli  | Ozomatli   | Cozcaquauhtli | 4                             | 9  | 14 | 19 |
| Ehecatl     | Mazatl     | Mallinalli | Ollin         | 5                             | 10 | 15 | 20 |
| Calli       | Tochtli    | Acatl      | Tecpatl       | 1                             | 6  | 11 | 16 |
| Cuetzpallin | Atl        | Ocelotl    | Quiauitl      | 2                             | 7  | 12 | 17 |
| Coatl       | Itzcuintli | Quauhtli   | Xochitl       | 3                             | 8  | 13 | 18 |

The names of the months are: Atlcaualco, Tlacaxipeualiztli, Tozoztontli, Uei Tozoztli, Toxcatl, Etzalcualiztli, Tecuiluitontli, Uei Tecuiluitl, Tlaxochimaco, Xocouetzi, Ochpaniztli, Teotleco, Tepelluitl, Quecholli, Panquetzaliztli, Atemoztli, Tititl, Izcalli and the supplementary days Nemontemi. The month-days seem to have been reckoned from 1 to 20. The monthly festivals regularly fell on the last month-day. In citing a date the practice was different from the Maya. The year-bearer was given and the day number and day name. Thus "year 3 Calli, day 1 Coatl." The month-day and the month were not given, and as there are 260 days in the Tonalamatl and 365 in the year, in certain cases a day name with its number may occur twice in the same year, thus causing an ambiguity. Often the year-bearer alone is given. When the Aztec had occasion to count a length of time they counted by years of 365 days, having none of the time periods of the Maya. The calendars of several other races of Mexico seem to have been similar with different names, but information is scanty regarding them. In all scientific knowledge the Aztec were much inferior to the Maya.

BIBLIOGRAPHY.—See CHRONOLOGY.

(R. C. E. L.)

#### MUSLIM

The era of the Hejira, commonly called the Mohammedan era, is used principally in Turkey, Persia, Arabia, Egypt and some parts of India. The era is dated from the first day of the month preceding the flight of Mohammed from Mecca to Medina. This day was Thursday, July 16 in the year A.D. 622. Hejira years are purely lunar, always consisting of 12 lunar months, beginning with the approximate new moon. Having no intercalation to keep them to the same season in respect to the sun, these years retrogress through all the seasons every  $3\frac{1}{2}$  years.

The names of the months and the number of days in each are as follows:—

|                    |    |                     |    |
|--------------------|----|---------------------|----|
| Muharram . . . . . | 30 | Rajab . . . . .     | 30 |
| Saphar . . . . .   | 29 | Shaaban . . . . .   | 29 |
| Rabia 1 . . . . .  | 30 | Ramadan . . . . .   | 30 |
| Rabia 2 . . . . .  | 29 | Shawwal . . . . .   | 29 |
| Jomada 1 . . . . . | 30 | Dulkaada . . . . .  | 30 |
| Jomada 2 . . . . . | 29 | Dulheggia . . . . . | 29 |

The last named month (Dulheggia) has, in intercalary years, 30 days. Ramadan, the ninth month, is observed throughout Islam as a fast month. (See CHRONOLOGY: Muslim.)

**CALENDER.** A machine consisting of two or more rollers or cylinders in close contact with each other, and often heated, through which are passed cotton, calico and other fabrics, for the purpose of having a finished smooth surface given to them; the process flattens the fibres, removes inequalities, and also gives a glaze to the surface. It is similarly employed in paper manufacture. The derivation is from the Fr. *calendre*, from the M<sup>ed</sup>. Lat. *calendra*, a cylinder.

Calendar is also the name (from the Arabic *galandar*) of an order of dervishes who separated from the Baktashite order in the 14th century; they were vowed to perpetual travelling. Other forms of the name by which they are known are Kalenderis, Kalendarites, and Qalandarites. (See DERVISH.)

**CALENUS, QUINTUS FUFIVS**, Roman general. As tribune of the people in 61 B.C., he helped to secure the acquittal of Clodius when charged with having profaned the mysteries of Bona Dea (Cicero, *Ad. Att.* i. 16). In 59 Calenus was praetor, and brought forward a law that the senators, knights, and *tribuni aerarii*, who composed the *iudices*, should vote separately, so that it might be known how they gave their votes (Dio Cassius xxxviii. 8). He fought in Gaul (51) and Spain (49) under Caesar; in 48, when fetching reinforcements for Caesar in Epirus, most of his ships were captured by Bibulus and he himself barely escaped. In 47 he became consul. After Caesar's

death he joined Antony, whose legions he afterwards commanded in the north of Italy. He died in 41, while preparing to march against Octavian.

See Caesar, B.G. viii. 39; B.C. i. 87, iii. 26; Cic. *Philippic* viii. 4.

**CALEPINO, AMBROGIO** (1435–1511), Italian lexicographer, born at Bergamo on June 6, 1435, was descended of an old family of Calepio, whence he took his name. He became an Augustinian monk and compiled a polyglot dictionary, first printed at Reggio in 1502. This gigantic work was afterwards augmented by Passerat and others. The most complete edition (Basle, 1590) comprises 11 languages. The best edition is that published at Padua in seven languages in 1772. Calepino died blind in 1511.

**CALES** (mod. CALVI), an ancient city of Campania, belonging originally to the Aurunci, on the Via Latina, 8m. N.N.W. of Casilinum. It was taken by the Romans in 335 B.C., and was for a long time the centre of the Roman dominion in Campania. It was an important base in the war against Hannibal. The fertility of its territory and its manufacture of black glazed pottery (see Pagenstecher, *Calenische Reliefkeramik*, Berlin, 1909, and C. L. Woolley in *Journal of Roman Studies*, i. 199), which was even exported to Etruria, made it prosperous. In the 5th century A.D. it became an episcopal see, which (jointly with Teano since 1818) it still is, though it is now a mere village. The cathedral, of the 12th century, has a carved portal and three apses decorated with small arches and pilasters, and contains a fine pulpit and episcopal throne in marble mosaic. Near it are two grottoes which have been used for Christian worship and contain frescoes of the 10th and 11th centuries. Inscriptions name six gates of the town, and the antiquarian remains are considerable, including parts of an amphitheatre and theatre, and of a supposed temple and other edifices.

**CALEXICO**, a city of Imperial county (Calif.), U.S.A., on the international border, opposite the Mexican city Mexicali; a port of entry, and the gateway to the Mexican Imperial valley. It is served by the Southern Pacific railway lines. The region produces cotton, fruit and live stock, and the city has large cotton gins. The population was 797 in 1910; 6,299 in 1930. The city was incorporated in 1908.

**CALF.** (1) The young of the *Bovidae*, and particularly of the domestic cow, also of the elephant and of marine mammals, as the whale and seal. The word is applied to a small island close to a larger one, like a calf by its mother's side, as in "Calf of Man," and to a mass of ice detached from an iceberg. (2) The fleshy hinder part of the leg, between the knee and the ankle.

**CALF, THE GOLDEN**, an object of worship which appears in two (apparently) different connections in the Old Testament: (a) the molten image whose making by Aaron in the absence of Moses is described in Ex. xxxii.; (b) an idol set up by Jeroboam I. at Bethel and at Dan, on the secession of the northern tribes from the kingdom of the house of David.

The calf- (or rather, bull-) cult of northern Israel is condemned by Hosea, and was regarded as an act of apostasy by the compilers of the Books of Kings, probably under the influence of Deuteronomy. At the same time no objection seems to have been raised till the latter half of the 8th century.

Bull worship was common both in Egypt and Palestine, and it has been conjectured that the narrative in Ex. xxxii. records an attempt to revive an older cult which the Israelites had known in Egypt. More probably, however, the narrative is a modified form of an ancient story told at Bethel, and possibly, also at Dan, to explain the cult—in other words the *hagios logos* of the shrine. If this be so, then the original probably made Moses himself, not Aaron, the originator of the cult, and explained that this was the divinely communicated form under which Yahweh wished to be worshipped. A later generation, convinced of the iniquity of any material representation of Yahweh, turned this into an act of apostasy and fathered it on Aaron, who elsewhere has hardly an independent character (see AARON). We may conjecture that the bull-cult itself was a native Canaanite form of Baal-religion, adopted by Israel with the change of the name of the deity revered.

See HEBREW RELIGION; W. R. Smith, *Prophets of Israel*, pp. 175 seq.; *Hastings' Dict. Bib.* i. 342; and T. H. Robinson on *The Golden Calif. Expositor*, 8th series, vol. xxiv. pp. 121 seq. (T. H. R.)

**CALGARY**, a city of the province of Alberta, Canada, at the junction of the Bow and Elbow rivers. Lat.  $51^{\circ} 4\frac{1}{2}'$  N.; Long.  $114^{\circ} 15'$  W. Pop. (1901) 4,091; (1931) 83,761. It is a centre of the large wheat-growing and stock-raising region of north-western Canada, and an important railway junction on the main line of the C.P.R. to the Pacific coast at Vancouver. The town is well laid out, with fine buildings, and is the seat of the Provincial Institute of Technology and Art. It contains repair shops, flour mills, and other industries; the electric power for lighting and manufacturing is developed on the Bow river, while natural gas is piped from the Bow island field, 100 m. distant, a good coal being also available from the mining districts of the Rocky mountains. Calgary was founded in 1883 and incorporated as a city in 1894. Branch lines connect it north with Edmonton, the capital of the province, and south with Lethbridge, while the main line, following the Bow river, enters the Rocky mountains through the Kicking Horse pass, 40 m. west of Calgary.

**CALHOUN, JOHN CALDWELL** (1782–1850), American statesman and parliamentarian, was born in Abbeville district, S.C., on March 18, 1782. He was of Scotch-Irish descent, his ancestors who came to America having settled originally in Pennsylvania during the first part of the 18th century and later gone southward across the mountains to the up-country of South Carolina. Calhoun's family were people of moderate means, owning but few negro slaves, and more representative of the frontier farming class than of the established and wealthy slave-holding families of the southern coastal plain section. His father, Patrick Calhoun, was a man of some prominence in his community, representing it in the colonial assembly, and later in the State legislature. Calhoun's mother's name was Martha Caldwell.

As a small boy, Calhoun had little opportunity for education, but when he was 12 years of age he was sent to live for a year in the family of his brother-in-law, the Rev. Moses Waddell (1770–1840), a Presbyterian minister, who subsequently, from 1819 to 1829, was president of the University of Georgia. Later, under the direction of the Rev. Waddell, he prepared for college, entering the junior class at Yale in 1802. In 1804 he graduated from Yale with distinction, and commenced the study of law at a law school at Litchfield, Conn. Thereafter, he completed his law studies in a law office in Charleston, S.C., and in 1807 was admitted to the bar, and began practice in his native Abbeville district. Almost at once he entered politics. In 1808 and 1809 he was a member of the South Carolina legislature, and from 1811 to 1817 he served as a member of the House of Representatives of the national legislature.

In the year that Calhoun entered Congress, he was married to a wealthy cousin, Floride Bonneau Calhoun, whose family was identified with the Charleston aristocracy, and this, together with the acquisition of a plantation and negroes, associated Calhoun's interests with those of the slave-holding and propertied classes of the South. However, when he ran for Congress in 1811, he advocated a warlike policy against Great Britain more as a representative of the frontier which was not concerned with British interference with shipping, but thought that her influence among the Indians was inimical to the western expansion of the United States. When Calhoun entered Congress, Henry Clay was then speaker of the House and one of the leaders of the group that was eager for war with England. Clay named Calhoun to a place on the important committee on foreign affairs. This committee, of which Calhoun soon became the dominating member, recommended the adoption of resolutions urging war with England. These resolutions were adopted by the House of Representatives, and it is estimated that no other two members of Congress were more influential in precipitating the War of 1812 than were Clay and Calhoun.

During the period of the embargo and during the War of 1812, manufacturing thrived in America, but with peace between the United States and Great Britain, and the termination of the Napoleonic régime on the continent of Europe, the American

manufacturers began to feel the effects of European competition. In discussion of the tariff proposals that resulted, Calhoun, in 1816, delivered a speech in favour of protection. Ever after this speech was cited by his opponents in subsequent tariff controversies as evidence of his inconsistency as an opponent of protection. At this time Calhoun also advocated internal improvements and was an exponent of the "Nationalism" advocated by the younger men of the West who were intent upon building up that section of the country and developing its resources.

In 1817 Calhoun became secretary of war in Monroe's cabinet, the duties of which office he is credited with having performed with much ability. Following his service in Monroe's cabinet, he was, in 1824, elected vice president of the United States, and again re-elected in 1828. In 1832, in the course of the famous nullification controversy, he resigned from the office of vice president and was elected to the U.S. Senate, where he voiced the political philosophy of "States' rights" on behalf of the conservative slave-holding interests of the South, forming one of a remarkable company of legislators who comprised the Senate at that time. In 1844 Calhoun's name was considered for the presidency, but he declined to become a candidate, and in that year was appointed by President Tyler to the office of secretary of State, serving until March 1845. Upon his retirement as secretary of State he returned to the Senate, where he remained until he died in 1850.

His extraordinary faculties of mind were applied very arduously to the fundamental principles of the American governmental structure, and he is justly looked upon as one of the most astute of political thinkers among the public men of the United States. The significance of his career, aside from his endeavours for supremacy in the field of national politics at a time when affairs were in the hands of men of striking personalities and unusual capacities, lies in his advocacy of the doctrine of "States rights," as it related to the interests of the slave-owning aristocracy of the South and of the concomitant theory of nullification. It has been sometimes thought that Calhoun's political philosophy was developed as a result of his failure to attain a dominating position in the national Government and to achieve the presidency of the United States, to which it is said he aspired, and that he naturally turned his energies to strengthening those political entities, his own State, and his own section, in which he had come to occupy a place of supremacy. It is, however, more reasonable to explain his support of the theories to which he adhered upon the ground that they were the result of a class and economic consciousness of the group to which he belonged as an integral part and which as a leader he was called upon to defend in the realm of political thought. The South as a section was losing its place of dominance politically and economically, and, in addition, was on the defensive with respect to the morality of the institution of slavery. Calhoun's philosophy served to check the opposing forces with a threat and eventually, when put into practice by secession, precipitated civil war.

The immediate cause of the controversy leading to an advocacy of the States' rights or strict construction theories was the tariff. In 1824 there was a very large increase in protective duties. In 1828 a still higher tariff act, the so-called "tariff of abominations" was passed. The acts were disadvantageous to the agricultural South and of advantage to the North. The power of Congress to pass these discriminatory laws was questioned, and Calhoun, in an essay, "The South Carolina Exposition," took the position that the Federal Constitution was a compact between sovereign States by which each delegated to the central Government thereby set up certain limited powers. The acts of the U.S. Government must be within the sphere of power contemplated by the compact. Acts beyond the scope of the delegated power a State might in the exercise of its sovereignty nullify, or it might, within its rights, even withdraw altogether from the Union. This was not a new theory in American government, but Calhoun so clarified, expounded and amplified the "State's rights" philosophy that he became inseparably identified with it.

In 1832, Calhoun, who had up to that time been a regular Jeffersonian Democrat, broke with Jackson, who was head of

the Party, and during the remainder of the Jackson régime, was a severe critic of Jacksonianism. He attacked the spoils system and opposed the removal of the Government deposits from the U.S. Bank. In 1831, in an "Address to the People of South Carolina," he elaborated his views as to the nature of the Union, and in 1832 addressed an essay letter to the governor of South Carolina, stating in final form his theory of the American governmental system. This last document resulted in the "nullification" by South Carolina of the Tariff acts of 1828 and 1832. There followed in 1833 the historic debate between Webster and Calhoun on the so-called "Force Bill," which had been introduced into the U.S. Senate to enlarge the jurisdiction of the Federal courts, and to give Jackson, as president, power to cope with the South Carolina situation. Webster maintained the doctrine of Federal supremacy as the expounder and interpreter of its own powers under the Constitution, while Calhoun argued the cause of State sovereignty. The opposing sides in this famous nullification controversy compromised. Congress reduced duties to an ultimate revenue basis, and South Carolina repealed the acts of nullification. Its consequence was, however, an acceptance by the South of Calhoun's doctrine as a protective political philosophy for slavery. To it and to Calhoun the slave-holding interests turned for a constitutional argument against any interference with the controverted institution. As the abolition movement developed and the question of the extension of slavery became a bitter one, it was Calhoun whose voice was heard in the Senate protesting on constitutional grounds against receiving abolition petitions, and it was under Calhoun's leadership that the forces opposing the Wilmot Proviso against the extension of slavery in the territory acquired from Mexico were marshalled and the Proviso defeated in the Senate. Calhoun took the extreme position that it was the duty of the U.S. Government under the Constitution to prevent any interference with slavery in the territories. In the course of the great debate on the admission of California into the Union as a free State, Calhoun died. In that controversy Webster made his famous "Seventh of March" speech, and Clay achieved his last great feat as peacemaker by the Compromise of 1850. Had Calhoun lived, the Compromise of 1850 might never have been made.

Calhoun was tall and slender, and in his later years emaciated. His features were angular and somewhat harsh, but he had a striking face and very fine eyes of a brilliant dark blue. To his slaves he was just and kind. He lived the modest unassuming life of a country planter when at home, and at Washington lived as unostentatiously as possible, consistent with his public duties and position. His character in other respects was of stainless integrity.

**BIBLIOGRAPHY.**—A collected edition of Calhoun's *Works* (1853-1855) has been edited by Richard K. Crallé. The most important speeches and papers are: *The South Carolina Exposition* (1828); *Speech on the Force Bill* (1833); *Reply to Webster* (1833); *Speech on the Reception of Abolitionist Petitions* (1836) and on the *Veto Power* (1842); a *Disquisition on Government*, and a *Discourse on the Constitution and Government of the United States* (1849-50)—the last two, written a short time before his death, defend with great ability the rights of a minority under a government such as that of the United States. *Calhoun's Correspondence*, edited by J. Franklin Jameson, has been published by the American Historical Association (see *Report* for 1899, vol. ii.). The biography of Calhoun by Dr. Hermann von Holst in the "American Statesmen Series" (1882) is a condensed study of the political questions of Calhoun's time. Wm. P. Trent, *Southern Statesmen of the Old Régime* (1897); G. M. Pinckney's *Life of John C. Calhoun* (1903) gives a sympathetic Southern view. Gaillard Hunt's *John C. Calhoun* (1908) is a valuable work; W. E. Dodd, *Statesmen of the Old South* (1911). (B. B. K.)

**CALI**, an inland town, capital of the department of Valle, Colombia, South America, about 180m. S.W. of Bogotá and 50m. S.E. of the port of Buenaventura, on the Rio Cali, a small branch of the Cauca. Pop. (1918) 45,825. Cali stands 3,327ft. above sea-level on the western side of the Cauca valley, one of the most healthful regions of Colombia. The land-locked character of this region greatly restricts the city's trade and development; but it is considered the most important town in the department. A railway from Buenaventura gives Cali and the valley behind it, with which it is connected by over 200m. of river navigation, a good

outlet on the Pacific coast. Coal deposits exist in the immediate vicinity of the town.

**CALIBRATION**, a term primarily signifying the determination of the "calibre," or bore of a gun. The word *calibre* was introduced through the French from the Italian *calibro*, together with other terms of gunnery and warfare, about the 16th century. The origin of the Italian equivalent appears to be uncertain. It will readily be understood that the calibre of a gun requires accurate adjustment to the standard size, and, further, that the bore must be straight and of uniform diameter throughout. The term was subsequently applied to the accurate measurement and

testing of the bore of any kind of tube, especially those of thermometers.

In modern scientific language, by a natural process of transition, the term "calibration" has come to denote the accurate comparison of any measuring instrument with a standard, and more particularly the determination of the errors of its scale. It is seldom possible in the process of manufacture to make an instrument so perfect that no error can be discovered by the most delicate tests, and it would rarely be worth while to attempt to do so even if it were possible. The cost of manufacture would in many cases be greatly increased without adding materially to the utility of the apparatus. The scientific method, in all cases which admit of the subsequent determination and correction of errors, is to economize time and labour in production by taking pains in the subsequent verification or calibration. This process of calibration is particularly important in laboratory research, where the observer has frequently to make his own apparatus, and cannot afford the time or outlay required to make special tools for fine work, but is already provided with apparatus and methods of accurate testing. For non-scientific purposes it is generally possible to construct instruments to measure with sufficient precision without further correction. The present article will therefore be restricted to the scientific use and application of methods of accurate testing.

**General Methods and Principles.**—The process of calibration of any measuring instrument is frequently divisible into two parts, which differ greatly in importance in different cases, and of which one or the other may often be omitted. (1) The determination of the value of the unit to which the measurements are referred by comparison with a standard unit of the same kind. This is often described as the *Standardization* of the instrument, or the determination of the *Reduction factor*. (2) The verification of the accuracy of the subdivision of the scale of the instrument. This may be termed calibration of the scale, and does not necessarily involve the comparison of the instrument with any independent standard, but merely the verification of the accuracy of the relative values of its indications. In many cases the process of calibration adopted consists in the comparison of the instrument to be tested with a standard over the whole range of its indications, the relative values of the subdivisions of the standard itself having been previously tested. In this case the distinction of two parts in the process is unnecessary, and the term calibration is for this reason frequently employed to include both. In some cases it is employed to denote the first part only, but for greater clearness and convenience of description we shall restrict the term as far as possible to the second meaning.

The methods of standardization or calibration employed have much in common even in the cases that appear most diverse. They are all founded on the axiom that "things which are equal to the same thing are equal to one another." Whether it is a question of comparing a scale with a standard, or of testing the equality of two parts of the same scale, the process is essentially one of interchanging or substituting one for the other, the two things to be compared. In addition to the things to be tested there is usually required some form of balance, or comparator, or gauge, by which the equality may be tested. One of the simplest of such comparators is the instrument known as the *callipers*.

from the same root as calibre, which is in constant use in the workshop for testing equality of linear dimensions, or uniformity of diameter of tubes or rods. The more complicated forms of optical comparators or measuring machines with scales and screw adjustments are essentially similar in principle, being finely adjustable gauges to which the things to be compared can be successively fitted. A still simpler and more accurate comparison is that of volume or capacity, using a given mass of liquid as the gauge or test of equality, which is the basis of many of the most accurate and most important methods of calibration. The common balance for testing equality of mass or weight is so delicate and so easily tested that the process of calibration may frequently with advantage be reduced to a series of weighings, as for instance in the calibration of a burette or measure-glass by weighing the quantities of mercury required to fill it to different marks. The balance may, however, be regarded more broadly as the type of a general method capable of the widest application in accurate testing. It is possible, for instance, to balance two electromotive forces or two electrical resistances against each other, or to measure the refractivity of a gas by balancing it against a column of air adjusted to produce the same retardation in a beam of light. These "equilibrium," or "null," or "balance" methods of comparison afford the most accurate measurements, and are generally selected if possible as the basis of any process of calibration. In spite of the great diversity in the nature of things to be compared, the fundamental principles of the methods employed are so essentially similar that it is possible, for instance, to describe the testing of a set of weights, or the calibration of an electrical resistance-box, in almost the same terms, and to represent the calibration correction of a mercury thermometer or of an ammeter by precisely similar curves.

**Method of Substitution.**—In comparing two units of the same kind and of nearly equal magnitude, some variety of the general method of substitution is invariably adopted. The same method in a more elaborate form is employed in the calibration of a series of multiples or submultiples of any unit. The details of the method depend on the system of subdivision adopted, which is to some extent a matter of taste. The simplest method of subdivision is that on the binary scale, proceeding by multiples of 2. With a pair of submultiples of the smallest denomination and one of each of the rest, thus 1, 1, 2, 4, 8, 16, etc., each weight or multiple is equal to the sum of all the smaller weights, which may be substituted for it, and the small difference, if any, observed. If we call the weights  $A, B, C$ , etc., where each is approximately double the following weight, and if we write  $a$  for observed excess of  $A$  over the rest of the weights,  $b$  for that of  $B$  over  $C + D + \dots$  etc., and so on, the observations by the method of substitution give the series of equations,

$$A - \text{rest} = a, B - \text{rest} = b, C - \text{rest} = c, \text{ etc. } \dots (1).$$

Subtracting the second from the first, the third from the second, and so on, we obtain at once the value of each weight in terms of the preceding, so that all may be expressed in terms of the largest, which is most conveniently taken as the standard

$$B = A/2 + (b - a)/2, C = B/2 + (c - b)/2, \text{ etc. } \dots (2).$$

The advantages of this method of subdivision and comparison, in addition to its extreme simplicity, are (1) that there is only one possible combination to represent any given weight within the range of the series; (2) that the least possible number of weights is required to cover any given range; (3) that the smallest number of substitutions is required for the complete calibration. These advantages are important in cases where the accuracy of calibration is limited by the constancy of the conditions of observation, as in the case of an electrical resistance-box, but the reverse may be the case when it is a question of accuracy of estimation by an observer.

In the majority of cases the ease of numeration afforded by familiarity with the decimal system is the most important consideration. The most convenient arrangement on the decimal system for purposes of calibration is to have the units, tens, hundreds, etc., arranged in groups of four adjusted in the propor-

tion of the numbers 1, 2, 3, 4. The relative values of the weights in each group of four can then be determined by substitution independently of the others, and the total of each group of four, making ten times the unit of the group, can be compared with the smallest weight in the group above. This gives a sufficient number of equations to determine the errors of all the weights by the method of substitution in a very simple manner. A number of other equations can be obtained by combining the different groups in other ways, and the whole system of equations may then be solved by the method of least squares; but the equations so obtained are not all of equal value, and it may be doubted whether any real advantage is gained in many cases by the multiplication of comparisons, since it is not possible in this manner to eliminate constant errors or personal equation, which are generally aggravated by prolonging the observations. A common arrangement of the weights in each group on the decimal system is 5, 2, 1, 1 or 5, 2, 2, 1. These do not admit of the independent calibration of each group by substitution. The arrangement 5, 2, 1, 1, 1 or 5, 2, 2, 1, 1, permits independent calibration, but involves a larger number of weights and observations than the 1, 2, 3, 4 grouping. The arrangement of ten equal weights in each group, which is adopted in "dial" resistance-boxes, and in some forms of chemical balances where the weights are mechanically applied by turning a handle, presents great advantages in point of quickness of manipulation and ease of numeration, but the complete calibration of such an arrangement is tedious, and in the case of a resistance-box it is difficult to make the necessary connections. In all cases where the same total can be made up in a variety of ways, it is necessary in accurate work to make sure that the same weights are always used for a given combination, or else to record the actual weights used on each occasion. In many investigations where time enters as one of the factors, this is a serious drawback, and it is better to avoid the more complicated arrangements. The accurate adjustment of a set of weights is so simple a matter that it is often possible to neglect the errors of a well-made set, and no calibration is of any value without the most scrupulous attention to details of manipulation, and particularly to the correction for the air displaced in comparing weights of different materials. Electrical resistances are much more difficult to adjust owing to the change of resistance with temperature, and the calibration of a resistance-box can seldom be neglected on account of the changes of resistance which are liable to occur after adjustment from imperfect annealing. It is also necessary to remember that the order of accuracy required, and the actual values of the smaller resistances, depend to some extent on the method of connection, and that the box must be calibrated with due regard to the conditions under which it is to be used. Otherwise the method of procedure is much the same as in the case of a box of weights.

**Method of Equal Steps.**—In calibrating a continuous scale divided into a number of divisions of equal length, such as a metre scale divided in millimetres, or a thermometer tube divided in degrees of temperature, or an electrical slide-wire, it is usual to proceed by a method of equal steps. The simplest method is that known as the method of Gay Lussac in the calibration of mercurial thermometers or tubes of small bore. It is essentially a method of substitution employing a column of mercury of constant volume as the gauge for comparing the capacities of different parts of the tube. A precisely similar method, employing a pair of microscopes at a fixed distance apart as a standard of length, is applicable to the calibration of a divided scale. The interval to be calibrated is divided into a whole number of equal steps or sections, the points of division at which the corrections are to be determined are called *points of calibration*.

**Slide-wire.**—The calibration of an electrical slide-wire into parts of equal resistance is precisely analogous to that of a capillary tube into parts of equal volume. The Carey Foster method, employing short steps of equal resistance, effected by transferring a suitable small resistance from one side of the slide-wire to the other, is exactly analogous to the Gay Lussac method, and suffers from the same defect of the accumulation of small errors unless steps of several different lengths are used. The calibration of a

slide-wire, however, is much less troublesome than that of a thermometer tube for several reasons. It is easy to obtain a wire uniform to one part in 500 or even less, and the section is not liable to capricious variations. In all work of precision the slide-wire is supplemented by auxiliary resistances by which the scale may be indefinitely extended. In accurate electrical thermometry, for example, the slide-wire itself would correspond to only 1°, or less, of the whole scale, which is less than a single step in the calibration of a mercury thermometer, so that an accuracy of a thousandth of a degree can generally be obtained without any calibration of the slide-wire. In the rare cases in which it is necessary to employ a long slide-wire, such as the cylinder potentiometer of Latimer Clark, the calibration is best effected by comparison with a standard, such as a Thomson-Varley slide-box.

**Graphic Representation of Results.**—The results of a calibration are often best represented by means of a correction curve, such as that illustrated in the diagram (*see* p. 585) which is plotted to represent the corrections in Table I. The abscissa of such a

possible, and should be automatically corrected during the process of ruling. With this object a scale is ruled on the machine, and the errors of the uncorrected screw are determined by calibrating the scale. A metal template may then be cut out in the form of the calibration-correction curve on a suitable scale. A lever projecting from the nut which feeds the carriage or the slide-rest is made to follow the contour of the template, and to apply the appropriate correction at each point of the travel, by turning the nut through a small angle on the screw. A small periodic error of the screw, recurring regularly at each revolution, may be similarly corrected by means of a suitable cam or eccentric revolving with the screw and actuating the template. This error is important in optical gratings, but is difficult to determine and correct.

**Calibration by Comparison with a Standard.**—The commonest and most generally useful process of calibration is the direct comparison of the instrument with a standard over the whole range of its scale. It is necessary that the standard itself should have been already calibrated, or else that the law of its

TABLE I. *Solution of Complete Calibration.*

| Step No.            | 1     | 2     | 3     | 4     | 5     | 6     | 7     | 8     | 9     | 10    |

curve is the reading of the instrument to be corrected. The ordinate is the correction to be added to the observed reading to reduce to a uniform scale. The corrections are plotted in the figure in terms of the whole section, taking the correction to be zero at the beginning and end. As a matter of fact the corrections at these points in terms of the fundamental interval were found to be -29 and -9 thousandths respectively. The correction curve is transformed to give corrections in terms of the fundamental interval by ruling a straight line joining the points +29 and +9 respectively, and reckoning the ordinates from this line instead of from the base-line. Or the curve may be replotted with the new ordinates thus obtained. In drawing the curve from the corrections obtained at the points of calibration, the exact form of the curve is to some extent a matter of taste, but the curve should generally be drawn as smoothly as possible on the assumption that the changes are gradual and continuous.

The ruling of the straight line across the curve to express the corrections in terms of the fundamental interval, corresponds to the first part of the process of calibration mentioned above under the term "Standardization." It effects the reduction of the readings to a common standard, and may be neglected if relative values only are required. A precisely analogous correction occurs in the case of electrical instruments. A potentiometer, for instance, if correctly graduated or calibrated in parts of equal resistance, will give correct relative values of any differences of potential within its range if connected to a constant cell to supply the steady current through the slide-wire. But to determine at any time the actual value of its readings in volts it is necessary to standardize it, or determine its scale-value or reduction-factor, by comparison with a standard cell.

A very neat use of the calibration curve has been made by Prof. W. A. Rogers in the automatic correction of screws of dividing machines or lathes. It is possible by the process of grinding, as applied by Rowland, to make a screw which is practically perfect in point of uniformity, but even in this case errors may be introduced by the method of mounting. In the production of divided scales, and more particularly in the case of optical gratings, it is most important that the errors should be as small as

indications should be known. A continuous current ammeter, for instance, can be calibrated, so far as the relative values of its readings are concerned, by comparison with a tangent galvanometer, since it is known that the current in this instrument is proportional to the tangent of the angle of deflection. Similarly an alternating current ammeter can be calibrated by comparison with an electro-dynamometer, the reading of which varies as the square of the current. But in either case it is necessary, in order to obtain the readings in amperes, to standardize the instrument for some particular value of the current by comparison with a voltmeter, or in some equivalent manner. Whenever possible, ammeters and voltmeters are calibrated by comparison of their readings with those of a potentiometer, the calibration of which can be reduced to the comparison and adjustment of resistances, which is the most accurate of electrical measurements. The commoner kinds of mercury thermometers are generally calibrated and graduated by comparison with a standard. In many cases this is the most convenient or even the only possible method. A mercury thermometer of limited scale reading between 250° and 400° C, with gas under high pressure to prevent the separation of the mercury column, cannot be calibrated on itself, or by comparison with a mercury standard possessing a fundamental interval, on account of difficulties of stem exposure and scale. The only practical method is to compare its readings every few degrees with those of a platinum thermometer under the conditions for which it is to be used. This method has the advantage of combining all the corrections for fundamental interval, etc., with the calibration correction in a single curve, except the correction for variation of zero which must be tested occasionally at some point of the scale.

**BIBLIOGRAPHY.**—Mercurial Thermometers: Guillaume, *Thermométrie de Précision* (1889), gives several examples and references to original memoirs. The best examples of comparison and testing of standards are generally to be found in publications of standards offices, such as those of the Bureau International des Poids et Mesures at Paris. Dial Resistance-Box: Griffiths, *Phil. Trans. A*, 1893; Platinum Thermometry-Box: J. A. Harker and P. Chappuis, *Phil. Trans. A*, 1900; Thomson-Varley Potentiometer and Binary Scale Box: Callendar and Barnes, *Phil. Trans. A*, 1901. (For calibration of a mercury thermometer, *see* article THERMOMETRY.) (H. L. C.)

**CALIBRE.** The diameter of the bore of a gun, not counting the depth of the rifled grooves.

**CALICO.** A trade term to describe the simplest variety of plain cotton fabrics embodying what is variously known technically as the "plain," "calico" and "tabby" weave. This simple fabric structure is evolved by the most elementary plan of interweaving two distinct series of threads, constituting the warp and the weft series, respectively, and which cross each other at right angles. Each individual thread of these two series interweaves in an exactly corresponding manner; *i.e.*, with every thread in each series passing alternately under and over consecutive threads of the other series, uniformly, throughout the entire fabric. Hence, every thread in each series interweaves to the uttermost possible extent with every thread in the other series, and thereby produces a texture which is relatively firmer and stronger than that of any other elementary weave structure, for corresponding counts and quality of yarn, and ends and picks per inch in the fabric.

Calico fabrics comprise an infinite variety of different textures and qualities according to the different uses for which they are intended, ranging from the finest muslin and cambric textures to those of the coarser and stronger textures of cotton. In the cotton trade, however, the term "calico" applies more strictly to a true plain cloth in which the counts and quality both of the warp and weft, and also the number of ends and picks per inch correspond, approximately. Thus, a typical example of a fine texture is one containing 100 ends and picks per inch, of 40's counts of yarn both for warp and weft, though these data may be varied in either direction with considerable latitude, without departing from the true calico texture. When these items correspond, either exactly or approximately, the resultant texture, whether this is fine or coarse, will be produced with a general evenness of surface in consequence of the threads of both series each bending and yielding in the fabric in an exactly corresponding measure.

**Tabby Weave.**—Plain cloths, *i.e.*, woven fabrics embodying the simple calico or "tabby" weave, are probably produced in a greater variety of textures and from every kind of textile material, than those of any other fundamental weave in the entire range of fabric structure. Plain cloths produced from cotton yarn ranging from, say, about 16's to 160's counts both for warp and weft, and containing any number of threads ranging from, say, about 40 to 160 ends and picks per inch, would come under the designation of "calicoes"; whereas the finer textures of plain cotton fabrics would be described as "muslins" and "cambrics"; whilst the heavier textures of plain cotton fabrics would be given such descriptions as heavy "sheetings," "canvas," "duck," and many other varieties.

Calico fabrics are almost invariably woven in the "grey" state; *i.e.*, in the natural colour of the raw cotton staple. A considerable quantity of calico is used in the grey state for domestic purposes, as well as for many trade and other uses. It is also shipped in large quantities all over the world. A considerable amount of calico is also bleached, dyed, and printed, for every conceivable household use and articles of clothing. (See CRETONNES.)

**Variations of Plain Calico.**—Although the plain calico weave is the simplest possible fabric structure, yet it permits of several distinct modifications in the development of different textural effects without departing in the very least from the essential basis of that structure as defined in the first part of this article. Thus, instead of employing warp and weft of similar counts of yarn, and inserting a corresponding number of ends and picks per inch, as in a true calico fabric, warp and weft of widely different counts may be employed in order to produce ribs and cords either across, lengthwise, or in both directions of the fabric. The ribs or cords will lie in the direction of the coarser threads and will be more or less pronounced according to the disparity in the respective counts. For example, a warp-ribbed effect is produced across the fabric by employing a greater number of warp threads of finer counts of yarn, per inch, with a fewer number of picks of coarser counts of weft, as exemplified in "poplins" and similar textures. By adopting the reverse method, a weft-ribbed or corded effect is produced lengthwise of the fabric, by employing yarn of coarser

counts for warp, and of finer counts for weft. The familiar example of "repp" fabric employed for upholstering railway carriages is virtually a plain texture evolved by employing yarn of both coarse and fine counts both in the warp and also in the weft series of threads, in order to develop a more pronounced ribbed effect, as well as a texture of greater strength and durability. (See also COTTON; WEAVING.)

See H. Nisbet, *Grammar of Textile Design* (1927).

(H. N.)

**CALICO PRINTING.** A means of producing decorative effects in the form of patterns or designs on cotton and other fabrics. The application of this art is not limited to the material generally known as calico, for almost all varieties of cotton fabric may be printed.

The effects produced are generally coloured, but many other substances besides colours are applied in printing, for example mordants to combine with colour principles in subsequent dyeing, "resists" to prevent dyeing, "discharges" to destroy the colour in certain places on already dyed fabric and substances capable of producing differences of texture and of lustre in the fabric.

The substance to be printed must either constitute or be made into a paste of such consistency that it will remain exactly where it is applied to the fabric and will not spread by capillary attraction beyond the limits of the design. With this object in view the substance is usually mixed with "thickening" which may be composed of such materials as starch, flour, British gum, gum tragacanth and less frequently albumen, casein or glue. Solutions used for the production of certain kinds of artificial silk may be already of such consistency that they can be applied directly for the purpose of producing a lustrous film. The mixture to be printed is prepared in the "colour" shop of the printworks and whether its essential constituent is or is not colour the paste produced is frequently known in the works as the "colour."

It is the essential substance printed or the manner in which this acts during or following printing which determines the "style" of printing. Only by ingenuity in the application of chemistry to "colour mixing," is it possible to satisfy the ever increasing demand for new and novel styles.

The local application of "colour" in the form of a pattern may also be carried out by the assistance of various instruments, but by far the most important is the *engraved cylinder* or *roller*. The first practically successful application of this form of printing machine was made in 1785 by Bell at the works of Livesey, Hargreaves and Co., near Preston. Roller printing is applicable to almost all types of ornament and fabric, it is capable of depositing from one to sixteen colours in a single printing operation and in one working day 18,000 yards of cloth can be printed in one colour and 8,000 to 9,000 yards in 12 colours. The pattern is engraved *intaglio* in fine lines or dots on a copper roller or in the case of a multicolour design as many rollers are engraved as the number of colours in the design demands and in the form taken by each colour which it is intended to print. This method of printing enables much detail in very fine designs to be clearly represented.

The *hand block* on which the pattern is cut in flat *relief* is unsurpassed for designs characterized by boldness and breadth of effect in rich transparent colours. By this method of printing which has been known from time immemorial such fabrics as cretonnes, table covers, curtains and chintz may be produced with fine effect. Although the method is necessarily slow it has never been superseded by any form of machine printing for certain classes of work.

In the best types of work whether produced by block or machine printing, it is not possible to observe any stiffness in the printed parts of the fabrics, for all starch or gum is removed. Moreover the results represent the combined efforts of artists, skilled craftsmen, chemists and engineers. (See TEXTILE PRINTING.)

(E. Hr.)

**CALICUT**, city, British India, headquarters of the Malabar district of Madras; on the coast, 6 m. N. of Beypore. Pop. (1921) 82,334. The weaving of cotton, for which the place was at one time so famous that its name became identified with its *calico*, is no longer of any importance. About the 7th century Calicut grew largely through the immigration of the Moplahs, fanatical

Mohammedans from Arabia.

The Portuguese traveller, Pero de Covilham (*q.v.*) visited Calicut in 1487, and described its possibilities for European trade; and in 1498 Vasco da Gama, the first European navigator to reach India, arrived at Calicut, then a flourishing city. Da Gama tried to establish a factory, but he met with persistent hostility from the local chief (*zamorin*), and a similar attempt made by Cabral two years later ended in the destruction of the factory by the Moplahs. In revenge the Portuguese bombarded the town; but no further attempt was made for some years to establish a trading settlement there. In 1509 the marshal Don Fernando Coutinho made an unsuccessful attack on the city. In the following year Albuquerque, with 3,000 troops, plundered the palace and burnt the town; but the Portuguese were finally repulsed, and fled to their ships after heavy loss. In the following year they concluded a peace with the *zamorin* and built a fortified factory, which was abandoned in 1525. In 1615 the town was visited by an English expedition; but it was not until 1664 that an English trading settlement was established by the East India Company. The French settlement, which still exists, was founded in 1698. The town was taken in 1765 by Hyder Ali, who expelled all the merchants, and destroyed the coconut trees, sandal-wood and pepper vines, that the country might not tempt Europeans. In 1782 Hyder's troops were driven from the town, but in 1788 it was destroyed by his son Tippoo, who, with great cruelty, carried off the inhabitants to Beypore. In 1790 the country was occupied by the British; and under the treaty concluded in 1792, whereby Tippoo was deprived of half his dominions, Calicut fell to the British. After this the inhabitants returned and rebuilt the town. Calicut is served by the Madras railway, and is the chief seaport on the Malabar coast, although steamers have to lie 3 m. offshore, and the port is practically closed during the south-west monsoon from the end of May to mid-August. Beypore, where there are eight wharves, is included in the port. Two piers, about 1½ m. apart, have recently been built at Calicut. The principal exports are coconut products, coffee, tea, pepper, ginger, etc. There are factories for coffee cleaning, cotton-mills, saw-mills and tile, oil and soap works. A detachment of European troops is generally stationed here to overawe the fanatical Moplahs. There are two colleges, a hospital of the Basle Mission, a fishery research station and a commercial school in the town.

**CALIDARIUM**, the hot room of the Roman baths (*see* BATHS).

**CALIDIUS, MARCUS**, Roman orator. His first speech of which we know was delivered in 64 B.C. against Gallius, who was defended by Cicero, for bribery. He was praetor in 57, and spoke in favour of Cicero's return and the restoration of his house. In the disturbances after Clodius' death he was a partisan of Milo. In the debate in the Senate in Jan. 49 he urged that Pompey should leave for his provinces to avoid war. On the outbreak of the Civil War he joined Caesar, who made him governor of *Gallia Togata*, where he remained till his death, at Placentia, in 48 B.C.

**BIBLIOGRAPHY**.—Cicero, *Brutus*, 79, 80, for a discussion of his style. Meyer, *Oratorum Romanorum Fragmenta*, 434; Westermann, *Gesch. der Rom. Beredsamkeit*, 69, 6–11.

**CALIFORNIA**, popularly known as the "Golden State," is one of the Pacific coast group of the United States of America. Physically it is one of the most remarkable, economically one of the most independent, and in history and social life one of the most interesting of the Union. It is bounded on the north by Oregon, east by Nevada and Arizona, from which last it is separated by the Colorado river, and south by the Mexican territory of Lower California, and west by the Pacific ocean. The extreme limits of California extend from 114° to 124° 29' W. and from 32° 30' to 42° N. The length of its medial line north to south is about 780m., its breadth varies from 150 to 350m., and its total area is 158,297 sq.m., of which 2,645 are water surface. The coast-line is more than 1,000m. long. In size California ranks second among the States of the Union. California was given the name "Golden State" because of its early and continued production of enormous quantities of gold.

**Physiography**.—The physiography of the State is simple; its main features are few and bold; a mountain fringe along the ocean, another mountain system along the east border, between them—closed in at both ends by their junction—a splendid valley of imperial extent, and outside all this a great area of barren, arid lands, belonging partly to the great basin and partly to the open basin region. Along the Pacific, and some 20–40m. in width, runs the mass of the Coast range, made up of numerous indistinct chains—most of which have localized individual names

BY COURTESY OF AMERICAN EXPRESS COMPANY

COLTON HALL, MONTEREY, CALIFORNIA, WHERE THE CONVENTION THAT FRAMED THE FIRST CONSTITUTION OF THE STATE MET IN 1849

—that are broken down into innumerable ridges and spurs, and small valleys drained by short streams of rapid fall. The range is cut by numerous fault lines, some of which betray evidence of recent activity; it is probable that movements along these faults cause the earthquake tremors to which the region is subject, all of which seem to be tectonic. The altitudes of the Coast range vary from about 2,000 to 8,000ft.; in the neighbourhood of San Francisco bay the culminating peaks are about 4,000ft. in height (Mt. Diablo, 3,856ft.; Mt. St. Helena, 4,343ft.), and to the north and south the elevation of the range increases. In the east part of the State is the magnificent Sierra Nevada, a great block of the earth's crust, faulted along its eastern side and tilted up so as to have a gentle back slope to the west and a steep fault escarpment facing east, the finest mountain system of the United States. The sierra proper, from Lassen peak to Tehachapi pass in Kern county, is about 430m. long (from Mt. Shasta in Siskiyou county to Mt. San Jacinto in Riverside county, more than 600 miles). Far higher and grander than the Coast range, the sierra is much less complicated, being indeed essentially one chain of great simplicity of structure. Precipitous gorges of canyons, often from 2,000 to 5,000ft. in depth, become a more and more marked feature of the range as one proceeds northward; over great portions of it they average not more than 20m. apart. The eastern slope is very steep, due to a great fault which threw the rocks of the great basin region abruptly downward several thousand feet. Few passes cross the chain. Between 36° 20' and 38° the lowest gap of any kind is above 9,000ft., and the average height of those actually used is probably not less than 11,000 feet. The Kearnsarge, most used of all, is still higher. Some 40 peaks are catalogued between 5,000 and 8,000ft., and there are 11 above 14,000. The highest portion of the system is between the parallels of 36° 30' and 37° 30'; here the peaks range from 13,000ft. upward, Mt. Whitney, 14,501ft., being the highest summit of the United States, excluding Alaska.

Of the mountain scenery the granite pinnacles and domes of the highest sierra opposite Owens lake, where there is a drop eastward into the valley of about 10,000ft. in 10m.; the snowy volcanic cone of Mt. Shasta, rising 10,000ft. above the adjacent plains; and the lovely valleys of the Coast range, and the south fork of the Kings river—all these have their charms; but most beautiful of all is the unique scenery of the Yosemite valley (*q.v.*). Much of the ruggedness and beauty of the mountains is due to the erosive action of many alpine glaciers that once existed on the higher summits, and which have left behind their evidences in valleys and amphitheatres with towering walls, polished rock-expanses, glacial lakes and meadows, and tumbling waterfalls. Remnants of these glaciers are still to be seen—as notably on Mt. Shasta—though shrunk to small dimensions. The canyons are

largely the work of rivers. The finest of the lakes is Tahoe, 6,225ft. above the sea, lying between the true sierras and the basin ranges, with peaks on several sides rising 4,000-5,000ft. above it. Clear lake, in the Coast range, is another beautiful sheet of water. Volcanic action has likewise left abundant traces, especially in the northern half of the range, whereas the evidences of glacial action are most perfect (though not most abundant) in the south. Lava covers most of the northern half of the range, and there are many craters and ash-cones, some recent and of perfect form. Of these the most remarkable is Mt. Shasta. In Owens valley is a fine group of extinct or dormant volcanoes.

Among the other indications of great geological disturbances on the Pacific coast may also be mentioned the earthquakes to which California like the rest of the coast is subject. They occur in all seasons, scores of tremors being recorded every year by the Weather Bureau; but they are of slight importance, and even of these the number affecting any particular locality is small. In 1812 great destruction was wrought by an earthquake that affected all the southern part of California; in 1868 the region about San Francisco was violently disturbed; in 1872 the whole sierra and the State of Nevada were shaken; in 1906 San Francisco (*q.v.*) was largely destroyed by a shock (and ensuing fire) that caused great damage elsewhere in the State; and in 1925 Santa Barbara was severely shaken. North of 40° N. lat. the Coast range and sierra system unite, forming an extremely rough country. The eastern half of this area is very dry and barren, lying between precipitous, although not very lofty, ranges; the western half is magnificently timbered, and toward the coast excessively wet. Between 35° and 36° N. lat. the sierra, at its southern end, turns westward towards the coast as the Tehachapi range. The valley is thus closed to the north and south, and is surrounded by a mountain wall, which is broken down in but a single place, the gap behind the Golden Gate at San Francisco. Through this passes the entire drainage of the interior. The length of the valley is about 450m., its breadth averages about 40m. if the lower foothills be included, so that the entire area is about 18,000 square miles. From the mouth of the Sacramento to Redding, at the northern head of the valley, the rise is 552ft. in 192m., and from the mouth of the San Joaquin southward to Kern lake it is 282ft. in 260 miles.

BY COURTESY OF THE SAN FRANCISCO CHAMBER OF COMMERCE  
VIEW IN SAN FRANCISCO LOOKING EASTWARD TOWARD THE CITIES OF OAKLAND AND BERKELEY ACROSS THE BAY, HERE ABOUT 4 M. WIDE

Two river systems drain this central basin—the San Joaquin, whose valley comprises more than three-fifths of the entire basin, and the Sacramento, whose valley comprises the remainder. The eastward flanks of the Coast range are very scantily forested, and they furnish not a single stream permanent enough to reach either the Sacramento or San Joaquin throughout the dry season. On the eastern side of both rivers are various important tributaries, fed by the more abundant rains and melting snows of the western flank of the sierra. The Feather is the most important tributary emptying into the Sacramento river. A striking feature of the Sacramento system is that for 200m. N. of the Feather it

does not receive a single tributary of any importance. Another peculiar and very general feature of the drainage system of the State is the presence of numerous so-called river “sinks,” where the waters disappear, either directly by evaporation or (as in Death valley) after flowing for a time beneath the surface. These “sinks” are therefore not the true sinks of limestone regions. Some of the mountain lakes show by the terraces about them that the water stood during the glacial period much higher than it does now. Tulare lake, which has practically disappeared, was formerly a shallow body of water, some 25 miles broad, that received the drainage of the southern Sierra, a flow that is believed to have shrunk greatly since 1850. The drainage of Lassen, Siskiyou and Modoc counties has no outlet to the sea and is collected in a number of alkaline lakes.

Finally along the sea below Point Conception are fertile coastal plains of considerable extent, separated from the interior deserts by various mountain ranges from 5,000 to 7,000ft. high, and with peaks much higher (San Bernardino, 11,600; San Jacinto, 10,800; San Antonio, 10,140). Unlike the northern sierra, the ranges of southern California are broken down in a number of places. It is over these passes—Soledad, 2,822ft., Cajon, 2,631ft.; San Geronimo, 2,560ft.—that the railways cross to the coast. That part of California which lies to the south and east of the Coast range and the sierra comprises an area of fully 50,000 sq.m. and belongs to the basin range region. For the most part it is excessively dry and barren. The Mohave desert—embracing parts of Kern, Los Angeles and San Bernardino, as also a large part of San Diego, Imperial and Riverside counties—belongs to the great basin, while a narrow strip along the Colorado river is in the open basin region. They have no drainage to the sea, save fitfully for slight areas through the Colorado river. In San Diego, Imperial and Riverside counties a number of creeks or so-called rivers, with beds that are normally dry, flow centrally towards the desert of Salton sink or sea; this is the lowest part of a large area that is depressed below the level of the sea—at Salton 263ft. and 276ft. at the lowest point. In 1900 the Colorado river (*q.v.*) was tapped south of the Mexican boundary for water wherewith to irrigate land in the Imperial valley along the Southern Pacific railway, south of Salton sea. The river enlarged the canal, and finding a steeper gradient than that to its mouth, was diverted into the Colorado desert, flooding Salton sink, and when the break in this river was closed for the second time, in Feb. 1907, a lake more than 400 sq.m. in area was left. The region to the east of the sierra, between the crest of that range and the Nevada boundary, is very mountainous. Near Owens lake the scenery is extremely grand. The valley here is very narrow, and on either side the mountains rise from 7,000 to 10,000ft. above the lake and river. Still farther to the east some 40m. from the lake is Death valley—the name a reminder of the fate of a party of “forty-miners” who perished here, by thirst or by starvation and exposure. Death valley, some 50m. long and, on an average, 20-25m. broad from the crests of the enclosing mountain ranges (or 5-10m. at their base), constitutes an independent drainage basin. It is 276ft. below sea-level, and altogether is one of the most remarkable physical features of California. The mountains about it are high and bare and brilliant with varied colours. The Amargosa river, entering the valley from Nevada, disappears in the salty basin. Enormous quantities of borax, already exploited, and of nitrate of soda, are known to be present in the surrounding country, the borax an almost pure borate of lime in Tertiary lake sediments. California has the highest land and the lowest land of the United States, and the greatest variety of temperature and rainfall.

**Climate.**—The climate is very different from that of the Atlantic coast; and indeed very different from that of any part of the country save that bordering California. In the first place, the climate of the entire Pacific coast is milder and more uniform in temperature than that of the States in corresponding latitude east of the mountains. Thus we have to go north as far as Sitka in 57° N. lat. to find the same mean yearly temperature as that of Halifax, Nova Scotia, in latitude 44° 39'. And going south along the coast, we find the mean temperature of San Diego 6° or 7° less than that of Vicksburg, Miss., or Charleston, S.C. In the

second place, the means of winter and summer are much nearer the mean of the year in California than in the east. This condition of things is not so marked as one goes inward from the coast; yet everywhere, save in the high mountains, the winters are comparatively mild. In the third place, the division of the year into two seasons—a wet one and a dry one—marks this portion of the Pacific coast in the most decided manner, being truly characteristic neither of Lower California nor of the greater part of Oregon, though more so of Nevada and Arizona. And finally, except on the coast, the disagreeableness of the heat of summer is greatly lessened by the dryness of the air and the consequent rapidity of evaporation.

Along both the Coast range and the sierra considerable rainfall is certain, although, owing to the slight snow accumulations of the former, its streams are decidedly variable. A heavy rain-belt, with a normal fall of more than 40in., covers all the northern half of the sierra and the north-west counties; shading off from this is the region of 10–20in. fall, which covers all the rest of the State save Inyo, Kern and San Bernardino counties, Imperial county and the eastern portion of Riverside county; the precipitation of this belt is from 0 to 10 inches. In the mountains the precipitation increases with the altitude; above 6,000 or 7,000ft. it is almost wholly in the form of snow; and this snow, melting in summer, is of immense importance to the State, supplying water at one time for placer-mining and later for irrigation. The north-west counties are extremely wet; many localities here have normal rain-falls of 60–70in. and even higher annually. Along the entire Pacific coast, but particularly north of San Francisco, there is a night fog from May to September. Below San Francisco the precipitation decreases along the coast, until at San Diego it is only about 10 inches. The extreme heat of the south-east is tempered by the extremely low humidity characteristic of the great basin. Many places in northern, southern, central, mountain and southern coastal California normally have more than 200 clear days in a year; and many in the mountains and in the south, even on the coast, have more than 250.

The Colorado desert (together with the lower Gila valley of Arizona) is the hottest part of the United States. Along the line of the Southern Pacific the yearly extreme is frequently from 124° to 129° F (*i.e.*, in the shade, which is almost, if not quite, the greatest heat ever actually recorded in any part of the world). At the other extreme temperatures of –20° to –36° are recorded yearly near Lake Tahoe. The normal annual means of the coldest localities of the State are from 37° to 44° F; the monthly means from 20° to 65° F. The normal annual means on Indio, Mammoth Tanks, Salton and Volcano springs are from 73.9° to 78.4° F; the monthly means from 52.8° to 101.3° (frequently 95° to 98°). Another weather factor is the winds, which are extremely regular in their movements. There are brisk diurnal sea-breezes, and seasonal trades and counter-trades. Along the coast an on-shore breeze blows every summer day; in the evening it is replaced by a night fog, and the cooler air draws down the mountain sides in opposition to its movement during the day.

There is the widest and most startling variety of local climates. There are points in southern California where one may actually look from sea to desert and from snow to orange groves. Distance from the ocean, situation with reference to the mountain ranges, and altitude are all important determinants of these climatic differences; but of these the last seems to be most important. Death valley surpasses for combined heat and aridity any meteorological stations on earth where regular observations are taken, although for extremes of heat it is exceeded by places in the Colorado desert.

**Soil.**—Sand and loams in great variety, grading from mere sand to adobe, make up the soils of the State. The plains of the north-east counties are volcanic, and those of the south-east, sandy. It is impossible to say with accuracy what part of the State may properly be classed as tillable. Much land is too rough, too elevated or too arid ever to be made agriculturally available; but irrigation, and the work of the State and national agricultural bureau in introducing new plants and promoting scientific farming, have accomplished much that once seemed impossible. Irriga-

tion was introduced in southern California before 1780, but its use was desultory and its spread slow till after 1850. In 1920, 4,219,040ac. were irrigated, an increase of 181% since 1900. More than half of this total was in San Joaquin valley. California has the greatest area of irrigated land of any State in the Union, and offers the most complete utilization of resources. In the south artesian wells, and in the great valley the rivers of the sierra slope, are the main sources of water-supply. On nearly all lands irrigated some crops will grow in ordinary seasons without irrigation, but it is this that makes possible selection of crops; practically indispensable for all field and orchard culture in the south, save for a few moist coastal areas, it everywhere increases the yield of all crops and is practised generally all over the State.

**Government.**—In the matter of Constitutions California has been conservative, having had only two. The first was framed by a convention at Monterey in 1849, and ratified by the people and proclaimed by the U.S. military governor in the same year. The present Constitution, framed by a convention in 1878–79, came into full effect in 1880, and was subsequently amended. It was the work of the Labour Party, passed at a time of high discontent, and goes at great length into the details of government, as was demanded by the state of public opinion. The qualifications required for the suffrage are in no way different from those common throughout the Union, except that by a constitutional amendment of 1894 it is necessary for a voter to be able to read the State Constitution and write his name. As compared with the earlier Constitution it showed many radical advances toward popular control, the power of the legislature being everywhere curtailed. Power was taken from the Legislature by specific inhibition in 31 subjects previously within its power. "Lobbying" was made a felony; provisions were inserted to tax and control common carriers and great corporations, and to regulate telegraph, telephone, storage and wharfage charges. The Constitution may be amended by a two-thirds vote of all the members elected to each house of the legislature, followed by ratification by a majority vote of the qualified electors voting on the proposition. Since 1911 amendments may be submitted directly to the people by means of the "initiative." A Constitutional Convention may be called by the legislature when two-thirds of all members of the legislature deem it necessary, provided the question is approved by a majority vote at the next

BY COURTESY OF U.S. BUREAU OF RECLAMATION  
YOUNG GRAPE VINEYARD IN THE IMPERIAL VALLEY, CALIFORNIA  
Modern cultivation using tractors in a district transformed by irrigation into a rich agricultural country producing a great variety of crops

general election. The work of the convention must be submitted to the people for approval or rejection.

The executive officers elected by the people of the State every four years are a governor, a lieutenant-governor, a secretary of State, a controller, a treasurer, a State board of equalization, a surveyor-general, an attorney-general and a superintendent of public instruction. Besides these executive and administrative officers, there are more than 50 boards, commissions, officers, etc., appointed by the governor, with or without the consent of the Senate. The legislature consists of two houses—a Senate of 40 members elected for four-year terms and an Assembly of 80 members elected for two-year terms. Regular sessions of the

legislature are held in the odd-numbered years and are divided into two parts, a recess of not less than 30 days separating the two sessions. In the second part no bill may be introduced into either house without the consent of three-fourths of its members, and no member may introduce more than two bills.

The judicial powers of the State are confined to a supreme court, three district courts of appeal, superior courts, and justice of the peace and police courts. The supreme court consists of

BY COURTESY OF THE LOS ANGELES CHAMBER OF COMMERCE  
THE NEW LOS ANGELES PUBLIC LIBRARY BUILDING

a chief justice and six associate justices elected by the people of the State for a term of 12 years. Regular sessions of the court are held in Sacramento, San Francisco and Los Angeles. The district courts of appeal have six judges each for the first and second district, and three judges for the third district; but in every case three judges constitute a separate court. Judges are elected by the votes of their respective districts for a term of 12 years. Each county has a superior court with one or more judges (Los Angeles county has 28) elected by the people for a term of six years. There is at least one justice of the peace for each township, elected for a period of four years. The Constitution of 1879 made provision for expediting trials and decisions. Notable was the innovation that agreement by three-fourths of a jury should be sufficient in civil cases and that a jury might be waived in minor criminal cases, a provision which was based on experience under the Mexican law.

The State is divided into 58 counties, and it is here that the chief administrative functions of local government take place. Municipalities are divided into six classes according to population. There is no uniform type of city government—the mayor-council, the commission and the city manager systems are all in common usage. Notable among the measures granting a greater popular control of the Government are the primary law of 1909 and the constitutional amendments of 1911 establishing the initiative and referendum, the recall (including the recall of judges), and the adoption of the short ballot.

**Population.**—The population of California in successive decades from 1850 to 1920 was as follows: 92,597 in 1850; 379,994 in 1860; 567,247 in 1870; 864,694 in 1880; 1,213,398 in 1890; 1,485,053 in 1900; 2,377,549 in 1910; 3,426,861 in 1920 or an increase of 44.1% for the last decade. According to the census figures in 1920 the State ranked in population eighth among the States of the Union. The population in 1930 was 5,677,251. The density of population in 1920 was 22 per sq.m.; in 1930 it was 36.5. The urban population (in places of 2,500 or more) in 1920 was 2,331,729, an increase during the decade from 61.8% to 68% of the total population. Of the cities, 47 had a population of 10,000 or more in 1930, and of this number three had more than 200,000 inhabitants; Los Angeles (1,238,048), San Francisco (634,394), and Oakland (284,063). Of the entire population in 1920, 3,264,711 were white, 38,763 negro, 17,360 Indian, 28,812 Chinese and 71,952 Japanese. During the decade 1910–20 the Chinese population decreased 7,436, while the Japanese increased

30,596. The State's total foreign-born population in 1920 was 681,662. Thirty-three countries contributed over 1,000 residents each, the leading ones being Italy, 88,502; Mexico, 86,610; Germany, 67,180; Canada, 59,562; England, 58,662; Ireland, 45,308; and Sweden, 31,925.

**Finance.**—Until 1910 the chief source of State and local revenue was a levy upon property. The system of taxation was so changed by a constitutional amendment in 1910 that State expense was to be borne by taxes on corporations, which were, on the other hand, relieved of county and local taxation. Other sources of State revenue were an inheritance tax, corporation licence fees, collected for the secretary of State and for the special funds, a gasoline (petrol) tax, motor vehicle licences, a compensation insurance tax, the sale of bonds and revenue derived from the school fund and lands. The chief disbursements were for general expenses, highways and education. The treasurer's report for the biennium ending June 30, 1926, showed receipts, including \$11,000,000 of bonds, of \$224,231,786, and disbursements amounting to \$211,594,807. These figures show an increase in receipts of 231% over the biennium ten years previous, and an increase in expenditures of 194% for the same period. The bonded indebtedness of the State amounted to \$100,350,500 on June 30, 1926. By an amendment to the Constitution, adopted in 1922, State expenditures are subject to an executive budget.

**Education.**—The educational system of California is one of the best in the country. It provides a complete system of free instruction from the kindergarten through the State university, and in the elementary and secondary schools even text-books and supplies are furnished without cost to individual pupils. At the

head of the public school system are the State superintendent of public instruction and the State board of education, a body consisting of seven members appointed by the governor. All schools are governed by a board of education. Outside the cities the school districts are governed by boards of trustees of three members, and, in the case of union districts, of five members. There was a compulsory attendance law passed in 1874 which has since been amended so as to require all children between the ages of eight and 16 to attend for the entire school year unless graduated from a four-year high school or exempted by the proper school authorities. Secondary schools are closely affiliated with, and inspected by, the State university. All schools are generously supported, salaries are usually good, and pension funds in all cities are authorized by State laws.

BY COURTESY OF THE NATIONAL PARK SERVICE  
THE GENERAL SHERMAN TREE IN THE GIANT FOREST OF SEQUOIA NATIONAL PARK, SAID TO BE THE OLDEST LIVING THING IN THE WORLD. ITS AGE HAS BEEN ESTIMATED AT 3,500 YEARS

The school population between the ages of five and 17 years, inclusive, was 779,692 in 1924. The public school enrolment for the same year was 1,022,130, or 131.1% as compared with the population between the ages of five and 17 years, a condition unique among the States of the Union. The distribution of the public school enrolment was 713,596 in kindergarten and elementary grades, and 308,534 in the secondary schools. There were, also, 37,765 pupils enrolled in private and parochial schools. The average number of days attended per pupil enrolled had decreased from 142 in 1910 to 125.2 in 1924. The total expenditure for the school year 1923–24, according to the *Statistical Abstract*, was \$124,241,000, or a per caput expenditure based on

## FRUIT-RAISING AND HARVESTING IN CALIFORNIA

1. View of cherry orchard in blossom in the Santa Clara valley, showing irrigation pipe outlets at the end of the rows. The water escapes through the vents in these pipes, each vent leading into a separate furrow
2. Peach-picking in the same orchard. As the buckets of peaches are transferred to the lug boxes, they are again inspected and any imperfect fruit not previously discarded by the pickers, is removed
3. View of Santa Clara valley, looking towards San Jose from the eastern side. The Santa Clara valley opens on San Francisco bay and extends in a southerly direction. It is bounded on the east by the Coast Range and on the west by the Santa Cruz mountains. Prunes as well as other fruits are raised in great quantities
4. A Harris Side Hill combined grain harvester at work in a field of grain near Stockton, California

### THE COAST AND INLAND COUNTRY OF CALIFORNIA

1. View of Emerald bay, a part of Lake Tahoe, the third largest fresh water lake in California. It is about 25 miles long. The water of the main lake is noted for its deep blue colour, while that of Emerald bay is crystal green
2. View of the rocky coast of Monterey, California, showing one of the residences which border the irregular shore
3. The sand dunes of Death valley, in Inyo county, California. This desert valley lies about 275 ft. below sea-level, and is one of the lowest land areas in the world. Borax deposits of immense extent are found in the valley
4. Part of Furnace Creek ranch, in southern California, showing the cultivation of the fan and feather palms. The tall fan palm grows wild in desert regions, but is cultivated widely in California
5. Yosemite falls, in the Yosemite national park. From a distance the falls give an impression of continuity, but the tremendous drop is in three stages; first, the Upper falls, then a series of cascades flowing south, and finally the Lower falls. The total height is 2,370 feet
6. A roadway in California lined with redwood trees. The redwood belt is situated chiefly in the Coast ranges of northern California. It consists of a series of groves extending from southern Oregon to Monterey

population 5-17, inclusive, of \$159.35, the highest among the States.

Of the higher educational institutions of the State the University of California, (*q.v.*) with the two main parts at Berkeley and Los Angeles, is by far the most important. In 1924 there were also seven State teachers' colleges located at Chico, Arcata, Fresno, San Diego, San Francisco, San José and Santa Barbara. There is also a State polytechnic school at San Luis Obispo. Among the endowed and denominational universities and colleges, Stanford university, near Palo Alto, is the greatest. It is privately endowed and is one of the richest educational institutions of America. Another university of large attendance and great importance is the University of Southern California, at Los Angeles.

**Agriculture.**—The rapid development of the spread of irrigation and of intensive cultivation, and the increase of small farms during the last few decades have made California an agricultural region and a great fruit-producing area. Staple products have changed with increasing knowledge of climatic conditions, of life-zones and of the fitness of crops. Irrigation has shown that with water, arid and barren plains, veritable deserts, may be made to bloom with immense wealth of semi-tropical fruits. The average size of farms in 1850, when the large Mexican grants were almost the only farms, was 4,466ac.; in 1910 it was 316.7ac., and in 1925 only 202 acres. In 1920 there were 29,365,667ac. in farms, of which 11,878,339ac. were improved land. The total acreage had fallen to 27,565,440 in 1925. The value per acre increased from \$47.16 in 1910 to \$94.77 in 1920 and to \$114 in 1925. In 1920 the total value of all farm property was \$3,431,021,861; this value had fallen to \$3,161,818,824 in 1925. There were 4,219,040ac. under irrigation in 1920. The total acreage devoted to agriculture in 1925 had the following distribution: main field crops, 4,551,200ac.; main fruit crops, 1,502,500ac.; and vegetable crops, 247,800ac. The average value per harvested acre was \$42.51 for field crops, \$101.60 for fruit, and \$98.50 for vegetables, giving total values of \$193,484,000, \$228,366,000, and \$52,047,000 for the respective crops, or a total value of \$473,897,000. Some idea of the character and value of these products can be secured from the table below, which shows the ranking of the 20 most valuable crops in 1925:

| Product                   | Farm value   |
|---------------------------|--------------|
| Oranges . . . . .         | \$79,200,000 |
| Hay, cultivated . . . . . | 75,796,000   |
| Barley . . . . .          | 24,180,000   |
| Raisin grapes . . . . .   | 23,850,000   |
| Wine grapes . . . . .     | 22,910,000   |
| Beans . . . . .           | 18,737,000   |
| Lemons . . . . .          | 18,000,000   |
| Wheat . . . . .           | 16,956,000   |
| Prunes . . . . .          | 15,950,000   |
| Cotton . . . . .          | 14,590,000   |
| Peaches . . . . .         | 14,430,000   |
| Walnuts . . . . .         | 13,420,000   |
| Lettuce . . . . .         | 13,134,000   |
| Potatoes . . . . .        | 13,020,000   |
| Cantaloupes . . . . .     | 9,872,000    |
| Pears . . . . .           | 9,412,000    |
| Rice . . . . .            | 8,055,000    |
| Table grapes . . . . .    | 7,776,000    |
| Asparagus . . . . .       | 7,698,000    |
| Tomatoes . . . . .        | 7,678,000    |

The live stock industry was introduced by the Franciscans and flourished throughout the pre-American period. In the development of the State under the American régime the live stock industry has been subordinate but not without economic significance. In 1925 dairy products had a value of \$126,480,746, the chief products being market milk, butter, ice cream, evaporated and condensed milk and market cream.

Horticultural products, as shown in the table, are the principal products of the soil. The modern orange industry practically began with the introduction into southern California in 1873 of two seedless orange trees from Brazil; from their stock have been developed, by budding, millions of trees bearing a seedless fruit which now holds high rank in the American market. Shipments continue all the year round. Southern California by no means

monopolizes the warm-zone fruits. Oranges, lemons and walnuts come chiefly from that section, but citrus fruits grow also in the sierra foothills of the great interior valley. Almonds and peaches, pears, plums, cherries and apricots, come mainly from the north. Over one-half of the prune crop comes from Santa Clara county, and the bulk of the raisin output from Fresno county. Olives thrive as far north as the head of the great valley. Vines were first introduced by the Franciscans in 1771 from Spain, and until 1860 "Mission" grapes were practically the only stock in California. Afterwards many hundreds of European varieties were introduced with great success.

**Fisheries.**—Fishing is a minor industry, but has great relative importance when compared with the product of the other States. In 1925 the yield of the fisheries of the State was 428,744,961lb. of fish, 8,872,118lb. of shell fish, and 2,683,436lb. of whale products; the total value for all products being \$11,661,709. The fish of chief importance are albacore, pilchard or sardine, and yellow fin tuna, each with a product valued in excess of \$1,000,000. Other species of great commercial importance are barracuda, cod, California halibut, salmon, striped tuna, blue fin tuna and yellow tail. In the canning of tuna fish, California has no rival. The pack of tuna and tuna-like fishes in 1926 was 851,199 standard cases, valued at \$5,282,283. In 1926, for the first time, California ranked first over Maine in the sardine industry. In that year, the 30 plants engaged in canning sardines packed 2,093,278 standard cases, valued at \$7,807,404.

**Manufactures.**—Previous to 1860 almost everything used in the State was imported from the East or from Europe. For many years manufacturing was handicapped by the State's lack of coal, but the opening of the petroleum fields and the increased use of the mountain streams to create electric power, obviated the difficulty. California had attained the rank of eighth among the States and first west of the Mississippi in the value of products manufactured in 1925. In that year there were 9,638 industrial establishments, giving employment to 249,552 wage-earners, and having an output valued at \$2,442,952,104. The industry of greatest importance was the refining of petroleum, which, in 1925, had a product valued at \$369,581,955, an output which made the State pre-eminent in the industry. The canning and preserving of fruit and vegetables was the State's second most valuable industry, with a product of \$181,272,830. In this field California stands without an equal. Other industries with a product in 1925 in excess of \$50,000,000 were: slaughtering and packing of meat, \$115,787,976; foundry and machine-shop products, \$80,653,577;

motor vehicles, \$78,442,568; printing and publishing newspapers and periodicals, \$77,876,415; lumber products, \$72,815,489; planing-mill products, \$68,910,812; bakery products, \$68,029,184; motion-pictures, \$62,821,194; and butter, cheese and evaporated and condensed milk, \$56,519,754. California leads the other States of the Union in the motion-picture industry, which centres chiefly in Hollywood.

In lumber production the State ranked sixth in 1925, when the cut for California was 2,043,000,000 board feet. The chief varieties were redwood, yellow pine, fir, sugar pine, cedar and spruce. In 1925 there were 19 national forest reserves within the State, with a combined area of 19,143,640ac. and a stand of commercial

timber estimated at 100,599,000,000 board feet. There are also three national parks, five national monuments, one State park and several small State forest reserves within the State.

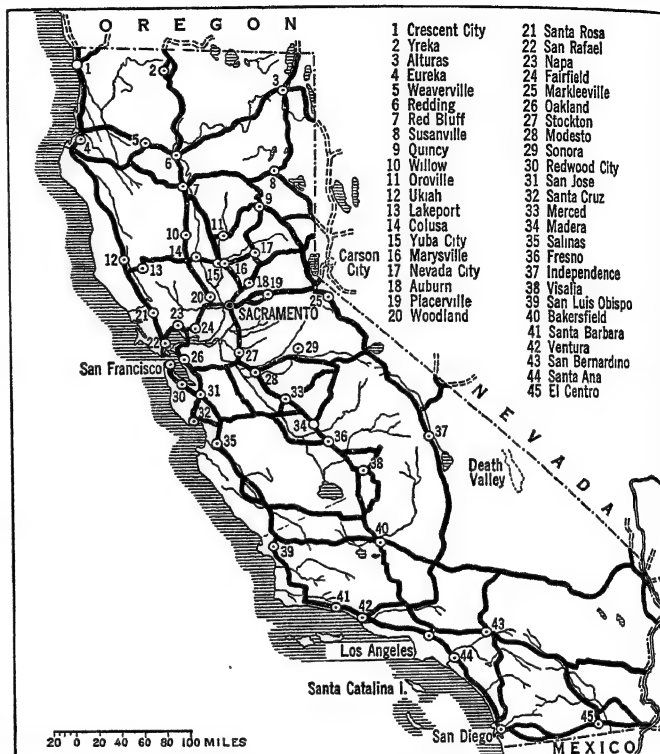

**Transcontinental Commerce.**—The transportation facilities in California increased rapidly after the completion of the first continental line in 1869 by the connection of the Central Pacific and Union Pacific lines. The New Orleans line of the Southern Pacific was opened in Jan. 1883; the Atchison, Topeka and Santa Fe owns the lines built to San Diego in 1885, and to San Francisco bay in 1900. Other railways of importance are the San Pedro and Salt Lake (the Union Pacific) and the Western Pacific. The total steam railway mileage, exclusive of switches and terminal roads, in the State on Dec. 31, 1924, was 8,334 miles. This was supplemented by 3,409m. of electric railways. After 1919 there was a rapid improvement in highways. The State highway system on Dec. 31, 1926, had a total mileage of 6,582.1, of which 3,537.9 were surfaced. The use of motor vehicles for passenger and freight transportation has increased rapidly within recent years. The total motor vehicle registration for 1925 was 1,440,541; an increase of over 146% since 1920.

There is now frequent freight and passenger service from San Francisco and Los Angeles (San Pedro) with Hawaii, Australia, and eastern Asia, as well as with American ports, both Atlantic and Pacific. Water-borne imports and exports for 1925 showed 1,383,664 cargo tons imported and 5,395,705 tons exported. San Francisco imported 895,849 tons as compared with 393,258 tons for Los Angeles; in the export trade Los Angeles had 3,231,141 cargo tons as compared with 1,838,148 for San Francisco. One of the remarkable developments within recent years is the growing importance of the dredged harbour of San Pedro, the port for Los Angeles. San Diego has a very good harbour but handles less tonnage than some of the secondary ports. The chief exports of California are petroleum, lumber, grains, fruit, vegetables and fish.

**Mineral Products.**—The existence of gold had long been suspected in California before 1848, and there had been desultory washings in parts where there was very little to reward prospectors. The first authenticated discovery was made near Los Angeles in 1842. The discovery of real historical importance was made on Jan. 24, 1848, at John A. Sutter's mill, on the south fork of the American river near Coloma, by a workman, James W. Marshall (1810-85). His monument marks the spot. At the time of their greatest productiveness, from 1850 to 1853, the highest yield of washings was probably not less than \$65,000,000 a year. From the record of actual exports and a comparison of the most authoritative estimates of total production, it may be said that from 1848 to 1856 the yield was almost certainly not less than \$450,000,000, and that about 1870 the \$1,000,000,000 mark had been passed. Placer-mining was of chief importance in the early years, but after the richer deposits had been exploited the machine-worked quartz mines came into prominence. In 1926 more than half of the gold output was from such mines. Quartz veins are very often as good at a depth of 3,000ft. as at the surface. A remarkable feature of the mining since 1900 is gold "dredging." Thousands of acres of land have been thus treated in recent years.

Gold was being produced in 1926 in about 25 counties in the east-central and northern part of the State. The production was 581,700 troy ounces valued at \$12,024,800; a value which gave California the rank of first among the States of the Union. Petroleum and products associated with it have an annual value far in excess of the historically important gold. The production of crude petroleum grew rapidly after 1895; its output increased from 4,325,000bbl. in 1900 to 262,876,000bbl. in 1923. In 1926 the production was 224,117,000bbls., with a well value of \$355,000,000. Oil is found from north to south over some 600m., but especially in southern California. The production came chiefly from Fresno, Kern, Los Angeles, Orange, Santa Barbara and Ventura counties. There was also a notable production in Sacramento, San Luis Obispo, San Joaquin and Solano counties. Natural gas gasoline was the State's second most valuable product in 1926, \$46,000,000 being its estimated value. Third in the rank of value in 1925 was natural gas, which was valued at \$32,587,000.

Cement (\$26,159,531) was the product fourth in importance, and clay products (\$21,324,844) were fifth. Other products in 1925 which had a value in excess of \$1,000,000 were: gold (\$13,065,330), stone (\$10,341,815), sand and gravel (\$8,752,528), copper (\$6,654,818), silver (\$2,119,765), and salt (\$1,420,924). Much of the world's mercury supply comes from a region about San Francisco bay, and practically the entire borax product of the

MAP OF THE MAIN ROADS OF CALIFORNIA

country comes from Death valley. The mineral production of California in 1925, valued at \$496,923,376, was exceeded by Pennsylvania and Oklahoma only; it represented 9.97% of the total mineral output of the United States. California, in 1925, ranked first among the States in the production of petroleum, gold, platinum, tungsten ore, chromite, mercury, magnesite, pyrites, silica (quartz), diatomaceous earth, potash, borates and sodium salts; second in natural gas and natural gas gasoline; third in cement; and fourth in talc and stone.

### HISTORY

"Gold made California!" The most important feature of modern Californian history is the way in which the territory came to be a part of the United States, with gold as the underlying dramatic element. Fear lest England or Russia might obtain California, and thus threaten Mexico, caused Spain at length to occupy it. Otherwise, quite probably the land might have fallen to England. The Spanish occupation merely kept others out, thus in fact serving to the ultimate advantage of the American Union, which would not have been strong enough to take over California much prior to the time when it actually did so. If the Spanish settlers had discovered California's gold, the destiny of the province would have been different from what it proved to be; in that event it might have become a Spanish-American republic, or England might have acquired it. The discovery of gold was postponed, however, until the Americans were already pouring into the province. Thereafter the rush of American settlers put the stamp of certainty on the connection with the United States.

**Exploration and Early Settlement.**—The name "California" was taken from Ordóñez de Montalvo's story, *Las Sergas de Esplandián* (Madrid, 1510), of black Amazons ruling an island of this name "at the right hand of the Indies . . . very close to that part of the Terrestrial Paradise." The name was given to

the southern part of Lower California probably in 1533-34, but at any rate before 1542. By extension it was applied in the plural to the entire Pacific coast north from Cape San Lucas. Necessarily the name had for a long time no definite geographic meaning. The lower Colorado river was discovered in 1540, but the explorers did not penetrate California; in 1542-43 Juan Rodríguez Cabrillo and his successor, Bartolomé Ferrello, explored probably the entire coast to a point just north of the

BY COURTESY OF THE U. S. BUREAU OF RECLAMATION  
HERD OF OSTRICH ON ONE OF CALIFORNIA'S OSTRICH FARMS

present boundary; in 1579 Sir Francis Drake repaired his ships in Drake's bay, and named the land New Albion; Spanish galleons en route from the Philippines to Acapulco usually sighted the coast, and certainly did so in the voyages of 1584 and 1595; and in a famous voyage of 1602-03 Sebastián Vizcaino carefully explored the coast, and discovered the Bay of Monterey. There was apparently no increase of knowledge thereafter for 150 years. Most of this time California was generally supposed to be an island or a group of islands. Jesuit missionaries entered Lower California as early as 1697, and maintained themselves there until expelled in 1768 by order of Charles III. of Spain; but not until Russian explorations in Alaska from 1745-65 did the Spanish Government take definite action to occupy Upper California. Because of the fear of foreign danger, and also the long-felt need of a refitting point on the California coast for the galleons from Manila, San Diego was occupied in 1769 and Monterey in 1770. San Francisco bay was discovered in 1769. Meanwhile the Jesuit property in the peninsula had been turned over to Franciscan monks, but in 1772 the Dominicans took over the missions, and the Franciscans not unwillingly withdrew to join their brethren who had gone with the expeditions of 1769 to Upper California. There they were to thrive remarkably for some 50 years.

**The Mission Period.**—This is the so-called "mission period" or the pastoral period of California history. In all, 21 missions were established between 1769 and 1823. Economically the missions were the blood and life of the provinces. At them the neophytes worked up wool, tanned hides, prepared tallow, cultivated hemp and wheat, raised a few oranges, made soap, some iron and leather articles, mission furniture, and a very little wine and olive oil. The hides and tallow yielded by the great herds of cattle at the missions were the support of foreign trade, and did much toward paying the expenses of the government. As for the intellectual development of the neophytes the mission system accomplished nothing; save the care of their souls they received no instruction, they were virtually slaves, and were trained into a fatal dependence, so that once coercion was removed they relapsed at once into barbarism. The missions, however, were only one phase of Spanish institutions in California. The government of the province was in the hands of a military officer stationed at Monterey. There were also several other military establishments and civilian towns in the province, as well as a few private ranches. The political upheavals in Spain and Mexico

following 1808 made little stir in this far-off province. When revolution broke out in Mexico (1811), California remained loyal to Spain. In 1820 the Spanish Constitution was duly sworn to in California, and in 1822 allegiance was given to Mexico. Under the Mexican Federal Constitution of 1824 Upper California, first alone (it was made a distinct province in 1804) and then with Lower California, received representation in the Mexican congress.

**Political Unrest.**—The following years before American occupation may be divided into two periods. From about 1840 to 1848 foreign relations are the centre of interest. From 1824 to 1840 there is a complicated and not uninteresting movement of local politics and a preparation for the future—the missions fall, Republicanism grows, the sentiment of local patriotism becomes a political force, there is a succession of sectional controversies and personal struggles among provincial chiefs, an increase of foreign commerce, of foreign immigration, and of foreign influence. The Franciscans were mostly Spaniards in blood and in sympathies. They viewed with displeasure and foreboding the fall of Iturbide's empire and the creation of the republic. After 1821 secularization of the missions was the burning question in California politics. Active and thorough secularization of the missions did not begin until 1834; by 1835 it was consummated at 16 missions out of 21, and by 1840 at all. In 1831 the mission question led to a rising against the reactionary clerical rule of Governor Manuel Victoria. He was driven out of the province. This was the first of the *opéra bouffe* wars. The causes underlying them were serious enough. In the first place, there was a growing dissatisfaction with Mexican rule, which accomplished nothing tangible for good in California, although its plans were as excellent as could be asked had there been peace and means to realize them. In the second place, there was growing jealousy between northern towns and southern towns, northern families and southern families. In 1831 Governor Victoria was deposed; in 1836 Governor Mariano Chico was frightened out of the province; in 1836 Governor Nicolás Gutiérrez and in 1844-45 Governor Manuel Micheltorena were driven out of office. The leading natives headed this last rising. There was talk of independence, but sectional and personal jealousies could not be overcome.

**Foreign Influence.**—By this time foreign influence was increasing. Foreign commerce, which was contrary to all Spanish laws, was active by the beginning of the 19th century. It was greatly stimulated during the Spanish-American revolutions, for, as the Californian authorities practically ignored the law, smuggling was unnecessary. In the early '40s some three-fourths of the imports, even at Monterey itself, are said to have paid no duties, being landed by agreement with the officials. American trade was by far the most important. The trade supplied almost all the clothing, merchandise and manufactures used in the province; hides and furs were given in exchange. If foreign trade was not to be received, still less were foreign travellers, under the Spanish laws. However, the Russians came in 1805, and in 1812 founded on Bodega bay a post they held till 1841, whence they traded and hunted (even in San Francisco bay) for furs. In 1826 American hunters first crossed to the coast; in 1830 the Hudson Bay Company began operations in northern California. The true overland immigration from the United States began only about 1840. As a class, foreigners were respected, and they were influential beyond proportion to their numbers. Many were naturalized, held generous grants of land, and had married into Californian families, not excluding the most select and influential. Most prominent of foreigners in the interior was John A. Sutter (1803-80), who held a grant of 11 square leagues around the present site of Sacramento, whereon he built a fort. Though Sutter himself was Swiss, his establishment became a centre of American influence. His position as a Mexican official, and the location of his fortified post on the border, made him of great importance in the years preceding and immediately following American occupation. Americans were hospitably received and very well treated by the Government and the people. There was, however, some jealousy of the ease with which they secured land grants, and an entirely just dislike of "bad" Americans. Many of the later comers

wanted to make California a second Texas. As early as 1805 (at the time of James Monroe's negotiations for Florida), there are traces of Spain's fear of American ambitions, even in this far-away province. Spain's fears passed on to Mexico, the Russians being feared only less than Americans. An offer was made by President Jackson in 1835 to buy the northern part of California, including San Francisco bay, but was refused. From 1836 on, foreign interference was much talked about. Americans supposed that Great Britain wished to exchange Mexican bonds for California; France also was thought to be watching for an opening for gratifying supposed ambitions; and all parties saw that, even without overt act by the United States, the progress of American settlement seemed likely to gain the province.

In 1842 Commodore T. A. C. Jones (1789-1858) of the U.S. navy, believing that war had broken out between his country and Mexico, and that a British force was about to seize California, raised the American flag over Monterey (Oct. 21), but finding that he had acted on misinformation, he lowered the flag next day with due ceremony and warm apology. In California this incident served to open up agreeable personal relations and social courtesies, but it did not tend to clarify the diplomatic atmosphere. By 1845 there was certainly an agreement in opinion among all American residents (then not 700 in number) as regards the future of the country. The American consul at Monterey, Thomas O. Larkin (1802-58), was instructed, in 1845, to work for the secession of California from Mexico, without overt aid from the United States, but with their good will and sympathy. He very soon gained from leading officers assurances of such a movement before 1848. At the same time American naval officers were instructed to occupy the ports in case of war with Mexico, but first and last to work for the good will of the natives.

In 1845 Captain J. C. Frémont (*q.v.*), while engaged in a Government surveying expedition, aroused the apprehensions of the Californian authorities by suspicious and, very possibly, intentionally provocative movements, and there was a show of military force by both parties. In violation of international amities, and practically in disobedience of orders, he broke the peace, caused a band of Mexican cavalry mounts to be seized, and prompted some American settlers to occupy Sonoma (June 14, 1846). This episode is known as the "Bear Flag War," inasmuch as there was short-lived talk of making California an independent State, and a flag with a bear as an emblem flew for a few days at Sonoma. Fortunately for the dignity of history, and for Frémont, it was quickly merged in a larger question, when Commodore John Drake Sloat (1780-1867) on July 7 raised the flag of the United States over Monterey, proclaiming California a part of the United States. The opening hostilities of the Mexican War had occurred on the Rio Grande. The aftermath of Frémont's filibustering acts, followed as they were by wholly needless hostilities and by some injustice then and later in the attitude of Americans towards the natives, was a growing misunderstanding and estrangement, regrettable in Californian history.

**A State of the Union.**—By the treaty of Guadalupe Hidalgo, in 1848, Mexico ceded California to the United States. Gold was discovered, and the new territory took on great national importance. The discussion as to what should be done with it began in Congress in 1846, immediately involving the question of slavery. A furious conflict developed, so that nothing was accomplished in two successive sessions; even at the end of a third, in March 1849, the only progress made toward creating a Government for the Territory was that the national revenue laws had been extended over it, and San Francisco had been made a port of entry. Meanwhile conditions grew intolerable for the inhabitants. Never was a population more in need of clear laws than the motley Californian people of 1848-49; yet they had none when, with peace,

military rule and Mexican law technically ended. Early in 1849 temporary local governments were set up in various towns, and in September a convention framed a free State Constitution and applied for admission to the Union. On Sept. 9, 1850, a bill finally passed Congress admitting California as a free State. This was one of the bargains in the "Compromise Measures of 1850."

Meanwhile the gold discoveries culminated and surpassed "three centuries of wild talk about gold in California." Settlements were completely deserted; homes, farms and stores abandoned. Ships deserted by their sailors crowded the bay at San Francisco—there were 500 of them in July 1850; soldiers deserted wholesale, churches were emptied, town councils ceased to sit, merchants, clerks, lawyers and judges and criminals, everybody in fact, flocked to the foothills. It is estimated that 80,000 men reached the coast in 1849, about one-half of them coming overland; three-fourths were Americans. Rapid settlement, excessive prices, reckless waste of money, and wild commercial ventures that glutted San Francisco with all objects usable and unusable, made the following years astounding from an economic point of view; but not less bizarre was the social development, nor less extraordinary the problems of State-building in a society "morally and socially tried as no other American community ever has been tried" (Royce). There was, of course, no home life in early California. In 1850 women numbered 8% of the population, but only 2% in the mining counties. Mining times in California brought out some of the most ignoble and some of the best traits of American character. Through varied instruments—lynch law, popular courts, vigilance committees—order was, however, enforced as time went on, until there was a stable condition of things.

The slavery question was not settled for California in 1850. Until the Civil War the division between the Whig and Democratic parties, whose organization in California preceded Statehood, was essentially based on slavery. The followers of Senator Gwin hoped to divide California into two States and hand the southern over to slavery; on the eve of the Civil War they considered the scheme of a Pacific coast republic. The State was thoroughly loyal when war came. The later '50s are characterized by H. H. Bancroft as a period of "moral, political and financial night." National politics were put first, to the complete ignoring of excessive taxation, financial extravagance, ignorant legislation, and corruption in California.

**Land Grants.**—One legacy that must be noted is that of disputed land grants. Under the Mexican régime such grants were generous and common, and the complicated formalities theoretically essential to their validity were very often, if not usually, only in part attended to. Instead of confirming all claims existing when the country passed to the United States, and so ensuring an immediate settlement of the matter, the U.S. Government undertook through a land commission and courts to sift the valid from the fraudulent. Claims of enormous aggregate value were thus considered, and a large part of those dating from the last years of Mexican dominion, many probably antedated after the commission was at work, was finally rejected.

In State gubernatorial elections after the Civil War the Democrats won in 1867, 1875, 1882, 1886, 1894; the Republicans were successful in all the other contests. Features of political life and of legislation after 1876 were a strong labour agitation, the struggle for the exclusion of the Chinese, for the control of hydraulic-mining, irrigation, and the advancement by State aid of the fruit interests. Labour conditions were peculiar in the decade following 1870. Mining, war times, and the building of the Central Pacific had up to then inflated prices and prosperity. Then there came a slump; probably the truth was rather that money was becoming less unnaturally abundant than that there was any over supply of labour. The dismissal by the Central Pacific lines (principally in 1869-70) of some 15,000 Chinese, who flocked to San Francisco, augmented the discontent of incompetents, of disappointed late immigrants, and the reaction from flush times. Labour unions became strong and demonstrative. This is called the "sand-lots agitation" from the favourite meeting-place (in San Francisco) of the agitators. The outcome

GRAPH SHOWING CHINESE AND JAPANESE POPULATION OF CALIFORNIA, 1880-1920

of these years was the Constitution of 1879, and the exclusion of Chinese by national law. Congress re-enacted exclusion legislation in 1902. All authorities agree that the Chinese in early years were often abused in the mining country and their rights most unjustly neglected by the law and its officers. The exclusion had much to do with making the huge single crop ranches unprofitable and in leading to their replacement by small farms and varied crops.

One outcome of early mission history, the "Pious Fund of the Californias," claimed in 1902 the attention of the Hague Tribunal (see ARBITRATION, INTERNATIONAL: *The Hague cases*). In 1906-07 there was throughout the State a remarkable anti-Japanese agitation, centring in San Francisco (*q.v.*) and affecting international relations and national politics. The Japanese question was brought to an acute situation in 1913 by the Webb Alien Land Holding Act, which prevented Japanese from holding real estate. The question was then taken up diplomatically between the United States and Japan, and as a result Japan agreed to the exclusion of further immigration of her citizens to the United States. The period 1910-25 was one of reforms, through the medium of legislative changes, which were both numerous and far-reaching. In addition to legislative enactments, 78 constitutional amendments were approved.

While these acts were generally recognized as having high social value, many of them added materially to the rapidly increasing cost of government. In 1919 the problem of governmental cost was made an object of special study and legislation, and in 1921 a remedy was sought by the consolidation of many State boards and commissions into a few State departments and also by raising the rate of the tax on corporations. This action brought forward the problem of State expense as an acute political issue, and resulted in the adoption of a constitutional amendment providing for an executive budget, and in the election of Friend W. Richardson as governor on a platform of strict economy. The prosecution of this programme divided the State into two political camps, one urging the full discharge of the social and educational responsibility of government, the other demanding relief from the burden of heavy taxation. In 1926 the first-named group was successful, and was able to procure the election of Clement Calhoun Young as governor.

**BIBLIOGRAPHY.**—For lists of works on California, see Robert E. Cowan, *A Bibliography of the History of California and the Pacific West, 1510-1906* (1914); Charles E. Chapman, "The Literature of California," in the *South-western Historical Quarterly* (vol. xxii., 1919); published in revised form in his *A History of California; the Spanish Period*; Eudora Garoutte, *Study Outline of California History* (1920); the University of California, *Library Bulletin*; and the catalogue of State official publications. The works of H. H. Bancroft have elaborate bibliographies with analyses and appreciations of many works.

The best short histories of California are: C. E. Chapman, *A History of California: the Spanish Period* (1921) and R. G. Cleland, *A History of California: the American Period* (1922). See also Henry K. Norton, *The Story of California from the Earliest Days to the Present Time* (1913); Irving B. Richman, *California Under Spain and Mexico 1535-1847* (1911); C. E. Chapman, *The Founding of Spanish California, 1687-1783* (1916); Z. S. Eldredge, editor, *History of California* (5 vol., 1915); and S. E. White, *The Forty-Niners; A Chronicle of the California Trail and El Dorado* (1918, Chronicles of America series). Of general scope and fundamental importance is the work of two men, Hubert H. Bancroft and Theodore H. Hittell. The former has published a *History of California, 1542-1890* (7 vol., San Francisco, 1884-90), also *California Pastoral, 1769-1848* (1888), *California Inter-Pocula, 1848-56* (1888), and *Popular Tribunals* (2 vol., 1887). These volumes were largely written under Bancroft's direction and control by an office staff, and are of very unequal value; they are a vast store-

house of detailed material which is of great usefulness. As regards events the histories are of substantial accuracy and adequacy. Written by one hand, and more uniform in treatment, is T. H. Hittell's *History of California* (4 vol., San Francisco, 1885-97).

The earliest historian of California was Francisco Palóu, a Franciscan, the friend and biographer of Serra; his most important work was "Noticias de la Nueva California" (Mexico, 1857) in the *Doc. Hist. Mex.*, ser. iv., tom. vi.-viii.; also San Francisco (4 vol., 1874). See in this connection Francisco Palóu, *Historical Memoirs of New California*, edit. H. E. Bolton (4 vol., Berkeley, 1927). Of the contemporary material on the period of Mexican domination the best is afforded by R. H. Dana, *Two Years Before the Mast* (1840, many later and foreign editions); also A. Robinson, *Life in California* (1846); and Alexander Forbes, *California: A History of Upper and Lower California from their First Discovery to the Present Time* (London, 1839); see also F. W. Blackmar, *Spanish Institutions of the South-west* (Johns Hopkins University Studies, 1891). A beautiful and vivid picture of the old society is given in Helen Hunt Jackson's novel, *Ramona* (New York, 1884). For mission period the standard Franciscan work is Zephyrin Engelhardt, *The Missions and Missionaries in California* (4 vol., San Francisco, 1908-15). Francisco Palóu, *Relación Histórica de la Vida . . . del Fray Junípero Serra* (Mexico, 1787), is an important contemporary source. On the "flush" mining years the best books of the time are J. Q. Thornton, *Oregon and California* (2 vol., New York, 1849); Edward Bryant, *What I Saw in California* (1848); W. Shaw, *Golden Dreams* (1851); Bayard Taylor, *Eldorado* (2 vol., 1850); W. Colton, *Three Years in California* (1850); and G. G. Foster, *Gold Regions of California* (1884). On this same period consult Bancroft, *Popular Tribunals*; D. Y. Thomas, "A History of Military Government in Newly Acquired Territory of the United States," in vol. xx., No. 2 (1904) of *Columbia University Studies in History, Economics, and Public Law*; C. H. Shinn, *Mining Camps: A Study in American Frontier Government* (1885); Mary F. Williams, *A History of the San Francisco Committee of Vigilance of 1851* (1921); J. Royce, *California . . . A Study of American Character, 1846-1856* (Boston, 1886); Cardinal L. Goodwin, *The Establishment of State Government in California, 1846-50* (1914); and, for varied pictures of mining and frontier life, the novels and sketches and poems of Bret Harte.

For government see David P. Barrows, *Government in California* (1925), an elementary work; the *California Blue Book*; and the reports of the various officers, departments, and administrative boards of the State Government. On population, industries, etc., consult the volume of the *Fourteenth United States Census*; the *Agricultural Year Book*; the biennial *Census of Manufactures*; the *California Agricultural Experiment Station, Bulletins* etc. See also C. F. Saunders, *Finding the Worth-while in California* (1930).

For physical features, mineral, flora, etc., see J. Muir, *Mountains of California* (New York, 1894); *United States Geological Survey, 19th Annual Report*, pt. 5, H. Gannet, *Forests of the United States*; *United States Division of Forestry, Bulletin* No. 28, "A Short Account of the Big Trees of California" (1900); No. 38, "The Redwood" (1 vol., 1903); W. L. Jepson, *The Trees of California* (1909, 2nd ed. 1923) and *Illustrated Manual of the Flowering Plants of California* (C. E. CH.)

**CALIFORNIA, LOWER** (*Baja California*), a long narrow peninsula between the Gulf of California and the Pacific ocean, forming a territory of the Republic of Mexico. Its population in 1910 was 52,272 and in 1921 was 62,831. Lower California is, geographically, a southward extension of the State of California, U.S.A., and is touched by only one of the Mexican States, that of Sonora on the north-eastern corner. The peninsula is about 760 m. in length, from 30 to 150 m. in width and has an area of 55,654 sq. miles. It is traversed throughout its length by an irregular range of mountains, which slopes gently toward the Pacific but breaks down abruptly toward the gulf. The coast has two or three good, sheltered bays, that of La Paz on the gulf side and that of Magdalena on the Pacific side being the best. The coast is bordered by numerous islands, particularly on the eastern side. The general appearance of the surface is arid and desolate, partly because of the volcanic rocks with which a large part of the land is covered, and partly because of the scanty rainfall, which is insufficient to support vegetation other than that of the desert, except in a few better watered valleys and on the high mountains of the north. The northern part of the peninsula, however, is much like southern California. Its climate is similar, with mild temperatures the year round on the Pacificward slope, and with light rains confined almost entirely to the winter season. The southern section is warmer and receives rain only in the summer. The central region is the most arid, being a pronounced desert. The Gulf coast, sheltered from the marine influence, is hot and dry, habitable only in a few widely separated valleys where water exists in sufficient quantities for irrigation. In such spots

GRAPH SHOWING GROWTH OF POPULATION IN CALIFORNIA, 1850-1930

sugar-cane, cotton, a few cereals and grapes are grown, but only to a limited extent. In the desert sections the only product of commercial importance is orchil or Spanish moss. The most productive agricultural region of Lower California is the extension of the Colorado river delta-plain southward of the Mexican-American border. Here, in 1925, there were 217,000 acres under intensive cultivation, being irrigated from the river and from the Imperial valley canal, which, for some 60 m. runs through Mexican territory. Cotton is the chief crop. The land is owned principally by Americans but the labourers employed are Mexicans and Asiatics. Some stock-raising is carried on in the better watered valleys of the peninsula and on the high mountains (the San Pedro Mártir range) in the north. The territory is quite rich in minerals. A little silver and gold is being mined in the northern district back of Ensenada; copper deposits are worked at Santa Rosalia and Mulegé on the east coast, while the southern district produces small amounts of silver and lead at San Antonio, El Triunfo and Cacachilas, north of Cape St. Lucas. The silver mines near La Paz were worked by the Jesuits as early as 1700. There are also extensive pearl fisheries in the gulf, La Paz being the headquarters of the industry, and whale fisheries on the west coast in the vicinity of Magdalena bay, where large catches are reported annually. The waters of the west coast also yield great quantities of sardines and tuna fish to many Dalmatian, Japanese and American fishermen, who make their headquarters at San Diego and San Pedro, Calif. The development of the territory has been delayed by lack of a railway system in the peninsula, no lines penetrating it except the San Diego-Arizona railway which runs south of the border for a short way between San Diego and Yuma.

The territory is divided into two districts, the northern having as its capital Mexicali (pop. 1921; 6,782) across the border from the Imperial valley of California, and the southern having its capital at La Paz, at the head of a deep bay opening into the Gulf. La Paz is a port of call for steamers running between Guaymas or Mazatlán and the west coast cities of the United States. In 1921 it had a population of 7,480. Ensenada (pop. in 1921; 2,178) 65 m. south of San Diego and connected with it by a motor road, is the only port for the northern Pacific coast of the territory, and supplies a district extending 250 m. along the coast and some 60 m. inland, including several mining centres, though it has no good roads except to the American border. Its chief activity is supplying border towns with alcoholic beverages. It was formerly the capital of the northern district.

By order of Cortés the coast of Lower California was explored in 1539 by Francisco de Ulloa, but no settlements resulted. It was named California at that time, the name being derived, apparently, from an island mentioned in a popular Spanish romance, *Sergas de Esplandián*. The name was at first applied exclusively to the peninsula; later, on the supposition that a strait connected the Pacific with the head of the Gulf of California, the name *Islas Californias*, was used. This theory was held as late as 1721.

The first European settlement was made in 1597, but was abandoned. A Jesuit mission was founded at Loreto in 1697 and another at La Paz in 1720. By 1776 there were 16 missions among the Indians. The settlement of Upper California began in 1769, with the founding of San Diego. In 1804 the region was divided into Alta and Baja Californias, but was reunited in 1825. Lower California was little disturbed by the struggle for independence in Mexico, but in the war between the United States and Mexico, La Paz and other towns were occupied by small detachments operating from California. In 1853 a filibustering expedition against Sonora under William Walker took possession of La Paz and proclaimed a republic consisting of Sonora and the peninsula. Fearing an attack from the mainland, the filibusters first withdrew to Ensenada, near the American border, and next year broke up during an attempt to invade Sonora by land.

**CALIFORNIA, UNIVERSITY OF**, a State university, with seats at Berkeley, Los Angeles, San Francisco and elsewhere. Control of the university lies in a board of regents, created by the State Constitution, and a president; the board comprises in its 24 members eight *ex officio* (including the president and the State governor) and 16 named by the governor for 16 year terms. Dr. William Wallace Campbell, astronomer and director of Lick observatory, is president, elected by the regents in 1923. The centre of administration is at Berkeley.

In the '60s, upon suggestion from Governor Low, the trustees of the College of California, founded in 1855, offered the college to the State. The gift, grounds and buildings in Oakland, the library of 10,000 vol. and the property of 160 ac. were worth about \$110,000. Accepting, the legislature appropriated \$306,661.80 as a university fund and secured California's share of the Federal land grant of 1862 in aid of education in agriculture and the mechanic arts. The university, chartered in 1868, opened its doors in 1869. In 1873 removal was made to its home on the slopes of the Berkeley hills, a site of great natural beauty, facing the Golden Gate. Here, 30 years later, the regents began to develop an enduring architectural plan based upon designs submitted by Emile Benard, of Paris, in a competition underwritten by Mrs. Phoebe Apperson Hearst (afterwards a regent) in 1896. By 1927, 16 buildings conforming to this plan were in use, eight provided by private donors, eight by the State. The dominant style is Italian Renaissance in white granite (seven buildings), and cement plaster on reinforced concrete. The Sather campanile, in granite, stands 302 ft. high. Noteworthy also are the stadium, seating 75,000, built by sale of scrip; Stephens hall, built by students and alumni for lounges, book-shop, restaurant and offices of students' publications and other activities, and an incomparable gymnasium for women, built in 1927 by William Randolph Hearst, a memorial to his mother, the regent. Twenty-four years earlier, in a hollow where the hills become abrupt, amid towering eucalyptus trees, Mr. Hearst had built the first modern Greek theatre, adapted under Roman influences from the fine example at Epidaurus, to seat 7,500. By 1927, also, the university grounds had been enlarged to embrace nearly 600 acres. In 1926, the people of California voted \$6,000,000 in bonds for university buildings. Two at Berkeley are an infirmary costing \$350,000 and a structure at \$2,000,000 to house 10 life science departments. The Los Angeles buildings—four, in the style known as Mediterranean, in terracotta and red—are the first upon the suburban Westwood site of 382 ac. given in 1926 by public-spirited individuals and groups to replace quarters outgrown. Between 1919, when the Los Angeles Normal school became the southern branch of the university, and 1926, when the regents named it formally the University of California at Los Angeles, its student roll increased from under 1,000 to nearly 6,000.

In San Francisco, in 1895, Adolph Sutro gave a hillside tract overlooking Golden Gate park, for the college of dentistry, the college of pharmacy and the medical school (with which later were associated the University hospital and the Hooper Foundation for Medical Research). Here, filled with invaluable ethnological material, stands the University Museum of Anthropology. On other premises are Hastings college of the Law and the California School of Fine Arts, affiliated with the university.

Two notable outposts are the Scripps Institution, endowed by the Scripps family, of Oceanography on a 168 ac. site at La Jolla, near San Diego; and the Lick observatory, gift of James Lick in 1875, on a 3,000 ac. site on Mt. Hamilton, 90 mi. south of Berkeley. The 36-in. refractor, the Crossley reflector (36½-in.), its almost ideal atmospheric conditions, its astronomers, have made the observatory one of the world's greater sources of cosmological knowledge. At Santiago, Chile, is a branch, the D. O. Mills observatory.

The unparalleled scope and variety of California farming cause the college of agriculture to be the university's largest and most complex department. Its annual budget exceeds \$2,000,000, nearly

one-eighth (\$227,060) coming from Federal sources. Its faculty numbers (1928) 350. Its largest unit, as also the university's, is the extension service, with a staff of 145 including 111 agents in 40 counties. The agricultural extension served 1,365 correspondence students in 1927, lectured to farm audiences numbering 630,197 persons, made upon invitation 51,713 calls at farms, had 95,913 office and 82,276 telephone discussions of farmers' problems, and answered 110,000 inquiries by letter. Its functions centre at Berkeley; its principal rural seat is 75 mi. north-east at Davis, in the Great Valley of California, where the university farm of 1,079 ac., with buildings worth \$1,250,000, engages experimenters and both matriculant and non-degree students. The college contains also the important Citrus experiment station and Graduate School of Tropical Agriculture at Riverside, occupying buildings valued at \$250,000 and 765 ac. of land. Including 135 ac. at Berkeley and 500 ac. in scattered parcels, the college uses more than 2,500 ac. in research and experimentation. It publishes *Hilgardia*, a technical journal, and many bulletins and reports.

At Berkeley are the schools of architecture, education, jurisprudence, librarianship and (in part) of medicine, and the colleges of letters and sciences, commerce, chemistry, civil engineering, mechanics and mining. The University of California at Los Angeles is in the main a college of letters and sciences; there is, besides, the teachers' college and, in affiliation, a graduate medical department. The faculties number, in all (excluding summer session and affiliated faculties), 1,700 professors and others engaged in teaching and research; of whom 800 are at Berkeley, 300 at Los Angeles, 300 at San Francisco, 300 at Davis, Riverside and elsewhere. The University of California was placed among the first five American universities by the editors of *American Men of Science* for 1927, with respect to strength of its scientific staff. For the year 1927-28, \$85,000 was appropriated for research projects in 35 departments, in addition to private gifts and endowment funds used for this purpose. The libraries contain nearly 1,000,000 vol., including the unique Bancroft collection of western Americana. Ten endowed chairs and 50 graduate scholarships and fellowships make also for productive scholarship. The university press expends \$50,000 annually in publishing the university's additions to knowledge. The university's assets, June 30, 1927, were \$43,210,458.96, including endowments, \$11,799,060.67. The year's income was \$12,056,106.02, covering \$6,201,957.93 State appropriation, \$475,599.20 from endowments, \$1,712,823.03 students' deposits. The year's private gifts amounted to \$2,129,414.18,—\$250,706.69 of which were for current use, \$745,195.41 for land, buildings, etc., and \$1,133,512.08 for endowment. Citizen residents of California are tuition-free at Berkeley, Los Angeles, and Davis, but all students pay small sessional fees in support of infirmary and certain services.

During the year 1926-27, the university conferred 2,658 degrees (1,281 upon women), including 211 masters of arts, 49 masters of science and 60 doctors of philosophy. By this time 37,027 degrees, in all, had been granted, nine-tenths of them since 1900. Nov. 1927 found enrolled 17,003 resident students; 9,997 (including 4,699 women) at Berkeley, 6,012 at Los Angeles (women 4,028), 860 in San Francisco (women 63), and 134 elsewhere. The Berkeley figure carries 1,996 in the graduate division, most of them candidates for teacher's certificates or advanced degrees. Many more thousands, mostly adults, are using the extension division, which during the year 1927-28 had 37,677 class enrolments throughout California and 6,690 throughout the world in correspondence courses, drew 285,000 persons to public lectures, and from its "film library," considered foremost of its kind, supplied cinema and stereopticon material for 5,263 public educational programmes.

Noteworthy recent benefactions are the bequest of William A. Clark, Jr., of his estate at Los Angeles, containing a library of 10,000 manuscripts and first editions; Mrs. Alexander F. Morrison's gift of 15,000 books for recreational reading, a memorial to her husband, in a room in the Doe library at Berkeley furnished and decorated by her at a cost of \$50,000; the men's dormitory at Berkeley, built by Mrs. Philip E. Bowles at a cost of \$350,000 in memory of her husband, a former regent; and \$1,750,000 from

John D. Rockefeller Jr., a gift prompted by the university's primacy in number of foreign students, to build at Berkeley an International House in which alien and native-born students might live together in furtherance of international understanding.

(R. G. S.)

**CALIFORNIA LILAC** (*Ceanothus thyrsiflorus*), a name given to a handsome North American tree of the buckthorn family (Rhamnaceae), called also blue blossom and blue myrtle. It grows on canyon sides from Monterey northward to Oregon and is especially abundant in the redwood belt. While usually a shrub, 3 ft. to 8 ft. high, it sometimes becomes a small tree 25 ft. in height with straight ascending branches. The small, smooth, oval or oblong leaves are green on both sides and shining above, with the edges minutely toothed. The showy blue or rarely white flowers are borne in dense clusters about 3 in. long. (See CEANOTHUS; NEW JERSEY TEA; OREGON TEA-TREE.)

**CALIFORNIA POPPY** (*Eschscholtzia californica*), a perennial herb of the poppy family (Papaveraceae), abundant in the valleys and foothills west of the Sierra Nevada. It has erect or diffusely spreading stems 1 ft. to 2 ft. long, bearing finely dissected leaves and large pale yellow to deep golden-orange flowers, 4 in. or more across, the petals glowing with a brilliant sheen. This plant, one of the most handsome and best-known representatives of the California flora, is now widely cultivated as an ornamental annual and has become extensively naturalized in India and Australia.

**CALIGULA (GAIUS CAESAR)** (A.D. 12-41), Roman emperor 37-41, youngest son of Germanicus and Agrippina the elder, was born on Aug. 31, A.D. 12. He grew up in his father's camp among the soldiers, and was called Caligula from the *caligae*, or soldiers' boots which he used to wear. He accompanied his father to Syria and after his death returned to Rome. In 32 he was summoned by Tiberius to Capreae, and by skilful flattery managed to escape the fate of his relatives. After the death of Tiberius, mysterious no doubt, but by no means certainly a murder, Caligula succeeded to the exclusion of Tiberius Gemellus, son of Drusus. The traditional account shows him received with rejoicing, and for eight months delighting everybody by general concessions, and in particular by reversing Tiberius' policy. Then apparently he had a very severe illness, and for the rest of his life was the usual monster of cruelty and vice with whom we become so familiar in the history of the Roman emperors, with a few added extravagances, such as bestowing the consulship on his horse, that seem only explicable on the ground of madness. In the case of a good many emperors there is some material whereby we can discount some of the excesses of senatorial history; in Caligula's, very little. This much is clear, Caligula is the earliest of a tradition that eventually prevailed, the pioneer of the oriental type of monarchy. His upbringing tended that way; he was brought up by his grandmother Antonia, and Herod Agrippa was a frequent visitor. Hence his insistence on personal deification, the extravagant honours paid to the imperial family, the increasing importance of the women of the palace. But his anti-Roman tendencies, which made him, perhaps even more than his cruelties, an abomination to the senatorial class which furnished the histories of the time, produced effects favourable to the provinces. The strictness with which Augustus and Tiberius kept the citizenship closed was relaxed. We find provincial *equites* growing numerous, provincial senators even. He also reversed the policy of Tiberius towards Eastern religions, and rebuilt the temple of Isis that Tiberius had destroyed.

Caligula's reign was undisturbed externally; there is only the abortive expedition to the coast opposite Britain. He was murdered by Cassius Chaerea, a tribune in the guard, on Jan. 24, 41. That he was the savage tyrant that he appeared to senatorial Rome seems probable, in spite of attempts at rehabilitation. It is a pity, however, that there is not more to show whether he was not, in other directions, something more.

See Suetonius, *Caligula*; Tacitus, *Annals*, vi. 20 sqq.; Dio Cassius lix. See also S. Baring Gould, *The Tragedy of the Caesars* (3rd ed., 1892); J. B. Bury, *Students' Hist. of the Roman Empire* (1893). Mention may also be made of the pamphlet by L. Quidde, *Caligula, Eine Studie über römischen Cäsarenwahnsinn*, and an anonymous

supplement, *Ist Calīgula mit unserer Zeit vergleichbar?* (both 1894); and a reply by G. Sommerfeldt, *Fin-de-Siècle-Geschichtsschreibung* (1895).

**CALINGA**, one of the nine kingdoms of southern India in ancient times. Its exact limits varied, but included the eastern Madras coast from Pulicat to Chicacole, running inland from the bay of Bengal to the Eastern Ghats. The name at one time had a wider and vaguer meaning, comprehending Orissa, and possibly extending to the Ganges valley. Rajahmundry, Coringa, Singapur, Calingapatam and Chicacole, have all been the chief cities of Calinga at different periods; but the capital of Calinga under the Ganga dynasty was probably at Mukhalingam in the Ganjam district.

**CALIPASH** and **CALIPÉE**, the gelatinous substances in the upper and lower shells, respectively, of the turtle, the calipash being of a dull greenish and the calipée of a light yellow colour (possibly connected with *carapace*, the upper shell of a turtle). Both are highly esteemed by epicures.

**CALIPH**, a title of the head of the Muslim community, first applied to Abū Bakr, as successor of Muḥammad (Arab, *khaliḥ* lit. "successor," "viceregent"). For other meanings of the word, see T. W. Arnold, *The Caliphate* (1924), Appendix C. (See also ISLAMIC INSTITUTIONS.)

**CALIPHATE**. The history of the Muhammadan rulers in the East who bore the title of caliph (*q.v.*) falls naturally into three main divisions:—(a) The first four caliphs, the immediate successors of Muḥammad; (b) The Umayyad caliphs; (c) The Abbasid caliphs. To these three groups the present article is confined; for the Western caliphs, see SPAIN: *History* (and minor articles such as ALMOHADES, ALMORAVIDES); for the Egyptian caliphs, see EGYPT: *History* (§Muhammadan) and FATIMITES. The history of Arabia proper will be found under ARABIA: *History*.

#### A.—THE FIRST FOUR CALIPHS

After the death of Muḥammad, homage was paid to Abū Bakr, as his successor.

1. **Reign of Abū Bakr**.—Abū Bakr's first task was the crushing of the revolt of the Bedouins who were compelled to submit. But the internal consolidation of Islam in Arabia was mainly brought about by its diffusion abroad. The holy war against the border countries which Muḥammad had already inaugurated, was the best means for making the new religion popular among the Arabs, for opportunity was also afforded for gaining rich booty. After the subjugation of middle and north-eastern Arabia, Khālīd b. al-Walīd proceeded by order of the caliph to the conquest of the districts on the lower Euphrates. Thence he was summoned to Syria, where hostilities had also broken out.

2. **Reign of 'Umar**.—Abū Bakr (d. Aug. 22, 634) was succeeded by 'Umar, to whose reign belong for the most part the great conquests. Damascus fell late in the summer of 635, and on Aug. 20, 636, was fought the great decisive battle on the Hieromax (Yarmūk), which caused the emperor Heraclius (*q.v.*) finally to abandon Syria. Left alone, the Christians henceforward defended themselves only in isolated cases in the fortified cities. Meanwhile the war was also carried on against the Persians in 'Iraq, unsuccessfully at first, until the tide turned at the battle of Qādisiyyah (end of 637). In consequence of the defeat which they here sustained, the Persians were forced to abandon the western portion of their empire and limit themselves to Iran proper. The Muslims made themselves masters of Ctesiphon (Madāin), the residence of the Sasanids on the Tigris, and conquered in the immediately following years the country of the two rivers. In 639 the armies of Syria and 'Iraq were face to face in Mesopotamia. In a short time they had taken from the Aryans all the principal old Semitic lands—Palestine, Syria, Mesopotamia, Assyria and Babylonia. To these was soon added Egypt, which was overrun with little difficulty by 'Amr ibn-al-Ās in 640. (See EGYPT: *History* §Muhammadan.)

The lapse of the masses from Christianity to Islam, which took place during the first century after the conquest, is to be accounted for only by the fact that in reality they had no inward relation to the Gospel at all. They changed their creed merely to

acquire the rights and privileges of Muslim citizens. In no case were they compelled to do so.

It would have been a great advantage for the solidity of the Arabian empire if it had confined itself within the limits of those old Semitic lands, with perhaps the addition of Egypt. But the Persians were not so ready as the Greeks to give up the contest; they did not rest until the Muslims had subjugated the whole of the Sasanid empire. The most important event in the protracted war which led to the conquest of Iran, was the battle of Nihāwand in 641; the most obstinate resistance was offered by Persis proper, and especially by the capital, Istakhr (Persepolis). In the end, all the numerous and partly autonomous provinces of the Sasanid empire fell, one after the other, into the hands of the Muslims, and the young king, Yazdagird III. (*q.v.*), was compelled to retire to the farthest corner of his realm, where he came to a miserable end. But the subjection of the Persians was only external, nor did Islam ever succeed in assimilating them as the Syrian Christians were assimilated.

'Umar's military policy aimed at making the whole Arab nation an army of soldiers; his internal policy was directed chiefly towards financial questions—the incidence of taxation in the conquered territories, and the application of the vast resources which poured into the Treasury at Medina. In the mosque at Medina he was stabbed by a Kufan workman and died in Nov. 644.

3. **Reign of 'Uthmān**.—Under the weak 'Uthmān, who was elected to succeed 'Umar, the government of Islam fell entirely into the hands of the Meccan aristocracy. 'Uthmān did all in his power to press forward this development of affairs. He belonged to the foremost family of Mecca, the Umayyads, and that he should favour his relations and the Quraysh as a whole, in every possible way, seemed to him a matter of course. Every position of influence and emolument was assigned to them.

Against the rising tide of worldliness an opposition, however, now began to appear, led by what may be called the spiritual noblesse of Islam. Everywhere in the provinces there was agitation against the caliph and his governors, except in Syria, where 'Uthmān's cousin, Mu'āwiyah, carried on a wise and strong administration. The movement was most energetic in 'Irāq and in Egypt. Its ultimate aim was the deposition of 'Uthmān in favour of 'Alī, whose own services as well as his close relationship to the Prophet seemed to give him the best claim to the Caliphate.

The malcontents demanded the abdication of 'Uthmān, besieging him in his own house, where he was defended by a few faithful subjects. As he would not yield, they at last took the building by storm and put him to death, an old man of eighty.

4. **Reign of 'Alī**.—Controversy as to the inheritance at once arose among the leaders of the opposition. The mass of the mutineers summoned 'Alī to the Caliphate, and compelled even Talḥa and Zubayr, disappointed candidates for the Caliphate, to do him homage. But soon these two, along with 'Ā'ishah, the mother of the faithful, who had an old grudge against 'Alī, succeeded in making their escape to 'Irāq, where at Baṣra they raised the standard of rebellion. The new caliph, however, found means of disposing of their opposition, and at the battle of the Camel, fought at Baṣra in Nov. 656 Talḥa and Zubayr were slain, and 'Ā'ishah was taken prisoner.

But even so 'Alī had not secured peace. With the murder of 'Uthmān the dynastic principle gained the twofold advantage of a legitimate cry—that of vengeance for the blood of the grey-haired caliph—and a distinguished champion, the governor Mu'āwiyah, whose position in Syria was impregnable. He exhibited 'Uthmān's blood-stained garment in the mosque at Damascus, and incited his Syrians to vengeance.

'Alī's position in Kūfa was much less advantageous. The population of 'Irāq was already mixed up with Persian elements; it fluctuated greatly, and was largely composed of fresh immigrants. Islam had its headquarters here; Kūfa and Baṣra were the home of the pious and of the adventurer, the centres of religious and political movement. This movement it was that had raised 'Alī to the Caliphate, but yet it did not really take any personal interest in him. Religion proved for him a less trustworthy and more dangerous support than did the conservative and secular feeling of

Syria for the Umayyads. Mu'āwiyah could either act or refrain from acting as he chose, secure in either case of the obedience of his subjects. 'Alī, on the other hand, was unable to convert enthusiasm for the principle inscribed on his banner into enthusiasm for his person. It was necessary that he should accommodate himself to the wishes of his supporters, who compelled him suddenly to break off the battle of Siffin, which he was apparently on the point of gaining over Mu'āwiyah because the Syrians fastened copies of the Qur'ān to their lances to denote that not the sword, but the word of God should decide the contest. But in yielding to the will of the majority he excited the displeasure of the minority, the genuine zealots; so when the negotiations failed and war was resumed, the Kharijites refused to follow 'Alī's army, and he had to turn his armies in the first instance against them. He defeated them at the battle of Nahrawān, but in his success he lost the soul of his following.

## B.—THE Umayyad Caliphs

1. **Reign of Mu'awiyah.**—Mu'āwiyah was a born ruler; Syria was the best administered province of the whole empire, and he was loved and honoured by the Syrians. On the murder of 'Alī in 661, his son Ḥasan was chosen caliph, but he recoiled before the prospect of a war with Mu'āwiyah, and resigning his position retired to Medina, where he died eight or nine years afterwards.

Mu'āwiyah now made his entry into Kūfa in the summer of 661 and received the oath of allegiance as Prince of the Believers. Just as soon as Mu'āwiyah had his hands free, he directed all his forces against the Greeks, and no year passed without a campaign. Twice he made a serious effort to conquer Constantinople, in 669 when he besieged it for three months, and in 674. In Africa also the extension of Muhammadan power was pursued energetically. In 670 took place the famous march of 'Uqbah b. Nāfi' and the foundation of Qayrawān, where the great mosque still bears his name.

The talented prefect of Kūfa, Mughīra broke down the resistance of Ziyād, who had been a faithful servant of 'Alī, and was said to be a bastard of Mu'āwiyah's father. Mu'āwiyah acknowledged him as the son of Abū Sufyān, and thus as his brother; in 664 this recognition was openly declared. In the next year Ziyād was appointed governor of Baṣra and the eastern provinces belonging to it. Mughīra died about 670, and the province of Kūfa also was entrusted to Ziyād. Kūfa and Baṣra were military colonies, and each tribe had its own quarter of the city. The policy of eastern expansion, which had been interrupted by the civil war, was resumed. The first army sent by Ziyād into Khurasan recaptured Merv, Herat and Balkh, conquered Tukhāristān and advanced as far as the Oxus. In 673 the son of Ziyād, crossed the river, occupied Bokhara, and returned laden with booty taken from the wandering Turkish tribes of Transoxiana. Other generals penetrated as far as the Indus and conquered Kabul, Sijistan, Makrān and Kandahar.

Ziyād governed 'Irāq with the greatest vigour, but as long as discontent did not issue in action, he let men alone. At his death (672-673), order was so generally restored that "nobody had any more to fear for life or estate, and even the unprotected woman was safe in her house without having her door bolted."

Mu'āwiyah was a typical Arab *sayyid* (gentleman). He governed, not by force, but by his superior intelligence, his self-control, his mildness and magnanimity. Mu'āwiyah was desirous of securing the Caliphate for his son Yazīd. The leadership with the Arabic tribes was, as a rule, hereditary, the son succeeding his father, but only if he were personally fit for the position, and were acknowledged as such by the principal men of the tribe. The hereditary principle had not been recognized by Islam in the cases of Abū Bakr, 'Umar and 'Uthmān, but had been adopted entirely for the election of Ḥasan. Mu'āwiyah succeeded in getting the succession of Yazīd generally acknowledged before his own death, except in Medina. He died in 680.

2. **Reign of Yazīd.**—On the news of Yazīd's accession, the numerous partisans of the family of 'Alī in Kūfa sent addresses to Ḥusayn, inviting him to take refuge with them, and promising to

have him proclaimed caliph in 'Irāq. Ḥusayn, having learned that the majority of the inhabitants were apparently ready to support him strenuously, prepared to take action. Meanwhile Yazīd, having been informed of the riotous behaviour of the Shi'ites in Kūfa, sent 'Ubaydallāh, son of the famous Ziyād and governor of Baṣra, to restore order. Using the same tactics as his father had used before, 'Ubaydallāh summoned the chiefs of the tribes and made them responsible for the conduct of their men. On the 8th of Dhu'l-Hijja Ḥusayn set out from Mecca with all his family, expecting to be received with enthusiasm by the citizens of Kūfa, but on his arrival at Karbala, west of the Euphrates, he was confronted by an army sent by 'Ubaydallāh under the command of 'Umar, son of the famous Sa'd b. Abi Waqqās, the founder of Kūfa. Ḥusayn gave battle, vainly relying on the promised aid from Kūfa, and fell, with almost all his followers, on Oct. 10, 680.

No other issue of this rash expedition could have been expected. But, as it involved the grandson of the Prophet, the son of 'Alī, and so many members of his family, Ḥusayn's devout partisans at Kūfa, who by their overtures had been the principal cause of the disaster, regarded it as a tragedy, and the facts gradually acquired a wholly romantic colouring. 'Umar b. Sa'd and his officers, 'Ubaydallāh and even Yazīd, came to be regarded as murderers, and their names have ever since been held accursed by all Shi'ites. They observe the 10th of Muharram, the day of 'Ashūra, as a day of public mourning. Among the Persians, stages are erected on that day in public places, and plays are acted, representing the misfortunes of the family of 'Alī. "Revenge for Ḥusayn" become the watchword of all Shi'ites, and the Mashhad Ḥusayn (Tomb of the martyr Ḥusayn) at Karbala is to them the holiest place in the world. 'Ubaydallāh sent the head of Ḥusayn to Damascus, together with the women and children. Yazīd was very sorry for the issue, and sent the prisoners under safe-conduct to Medina.

Ibn Zubayr profited greatly by the distress caused by Ḥusayn's death. He had himself secretly addressed as caliph, and many of the citizens of Medina acknowledged him as such. Yazīd, when informed of this, sent an army with orders first to exact submission from the Medinians, if necessary by force, and then to march against Ibn Zubayr. The Medinians fought valiantly, but could not hold out against the well-disciplined Syrians, and for three days the city was given up to plunder. But the city recovered very soon from the disaster, and remained the seat of holy tradition and jurisdiction, and of the Arabic aristocracy.

The army arrived before Mecca in Sept. 683 and found Ibn Zubayr ready to defend it. The siege had lasted 65—others say 40—days, when the news came of the death of Yazīd, which took place presumably on Nov. 12, 683; whereupon the army returned to Syria. Ibn Zubayr now openly assumed the title of caliph and invited men to take the oath of allegiance. He was soon acknowledged throughout Arabia, in Egypt and in 'Irāq.

3. **The Son of Yazīd.**—Mu'āwiyah II. had reigned a very short time when he fell sick and died. Marwān b. Ḥakam, of another branch of the Umayyads, who had been 'Uthmān's right-hand man, was proclaimed caliph and defeated the supporters of Ibn Zubayr in a battle (A.D. 684) which ensued at Marj Rāḥit, near Damascus.

4. **Reign of Marwān I.**—After the victory of Marj Rāḥit, Marwān conquered Egypt, and installed as governor his second son. An army sent to the rescue by Ibn Zubayr under the command of his brother Muṣ'ab was beaten in Palestine.

Meanwhile Mukhtār, a man of great talents and still greater ambition, after having supported Ibn Zubayr in the siege of Mecca, had gone to Kūfa, where he joined the Shi'ites, mostly Persians, and acquired great power. He claimed to be the vice-regent of 'Alī's son, Muḥammad ibn al-Hanafīyya, who after the death of Ḥusayn was recognized by the Shi'ites as their Mahdī. Ibn Zubayr's representative in Kūfa was compelled to flee, and all those who had participated in the battle of Karbala were put to death. Ibn Zubayr, determined to get rid at all costs of so dangerous an enemy, named his brother Muṣ'ab governor of Baṣra and ordered him to march against Kūfa. Mukhtār fell, and with him the ephemeral dominion of the Persian Shi'ites. This had

been their first attempt to dispute the authority of their Arabian conquerors, but it was not to be the last.

5. **Reign of 'Abdalmalik.**—Marwān died on May 7, 685. The accession of his son, 'Abdalmalik, was attended with no difficulty, but the first years of his reign were occupied by troubles in northern Syria, and it was not until 689 that he made an expedition into 'Irāq to break Muṣ'ab, who in 691 was slain, sword in hand, by a Shi'ite of Kūfa.

This victory opened the gates of Kūfa to 'Abdalmalik, and all 'Irāq received him with acclamation. Thence, a few days later, he sent Ḥajjāj b. Yūsuf at the head of 2,000 Syrians against Ibn Zubayr in Mecca. In 692 Mecca was invested. The blockade lasted more than six months, during which the city was a prey to all the horrors of siege and famine, which at length triumphed over the last adherents of Ibn Zubayr; he resolved to die, and, when the Umayyad troops made their way into the city, attacked them furiously, notwithstanding his advanced age, and was slain. His head was cut off, and sent by Ḥajjāj to Damascus.

The caliph committed to Ḥajjāj the government of the Hijāz, and, later, made him governor of 'Irāq also with the most extensive powers. In Kūfa Ḥajjāj ordered that every man capable of bearing arms should immediately join Muhallab in Khūzistān (Susiana), and swore that all who should be found in the town after the third day should be beheaded. This threat had its effect, and Ḥajjāj proceeded to Baṣra, where his presence was followed by the same results. Muhallab, reinforced by the army of 'Irāq, at last succeeded, after a struggle of 18 months, in subjugating the Khārijites, and was able in 697 to return to Ḥajjāj at Baṣra. The latter loaded him with honours and made him governor of Khurasan, whence he directed several expeditions into Transoxiana. In the east the realm of Islam had been very much extended under the reign of Mu'āwiyah, when Ziyād was governor of 'Irāq and Khurasan. Balkh and Tokhāristān, Bokhara, Samarkand and Khwarizm (modern Khiva), even Kabul and Kandahar had been subdued; but in the time of the civil war a great deal had been lost again. Now at last the task of recovering the lost districts could be resumed. When, in 697, Ḥajjāj gave the government of Khurasan to Muhallab, he committed that of Sijistān (Seistan) to 'Ubaydallāh, a cousin of Ziyād. This prefect allowed himself to be enticed by Zanbīl, prince of Zabulistan, to penetrate into the country far from his base, and narrowly escaped, not without severe losses. The command over Sijistān was now given to Ibn Ash'ath, who soon after his arrival in Sijistān, exasperated by the masterful tone of Ḥajjāj towards himself, decided to revolt. The soldiers of 'Irāq, who did not love the governor, and disliked the prospect of a long and difficult war far from home, eagerly accepted the proposition of returning to 'Irāq, and even proclaimed the dethronement of 'Abdalmalik, in favour of Ibn Ash'ath. When Ḥajjāj came up with him, Ibn Ash'ath drove him back to Baṣra, entered the city, and then turned his arms against Kūfa, of which he took possession with aid from within. In July 702, a decisive action took place at Dayr al-Jamājim. Ibn Ash'ath, defeated, fled to Baṣra; but having been again beaten in a furious battle that took place at Maskin near the Dujail, he sought an asylum with the king of Kabul, who betrayed him; so he killed himself. His head was sent to Ḥajjāj and then to Damascus. This happened in the year 703 or 704.

The struggle of Ibn Ash'ath was primarily a contest for hegemony between 'Irāq and Syria. The proud lords could not acquiesce in paying to a plebeian like Ḥajjāj, invested with absolute power by the caliph, the strict obedience he required. They considered it further as an injustice that the Syrian soldiers received higher pay than those of 'Irāq. Moreover, Ḥajjāj, in order to maintain the regular revenue from taxation, had been obliged to introduce stringent regulations, and had compelled a great many villagers who had migrated to the cities to return to their villages.

Immediately after the victories of Dayr al-Jamājim and Maskin, in 702, Ḥajjāj, built a new residence on the Tigris, between Baṣra and Kūfa, which he called Wāsiṭ ("Middle"). There his Syrian soldiers were not in contact with the turbulent

citizens of the two capitals, and were at any moment ready to suppress any fresh outburst.

As soon as the expedition to 'Irāq against Muṣ'ab had terminated, the holy war against the Greeks was renewed. From this time forth the Muslims made yearly raids, the chief advantage of which was that they kept the Syrian and Mesopotamian Arabs in continual military exercise. In the year 696 'Abdalmalik sent into Africa a numerous army, which swept the coast as far as Carthage, expelling the Greek garrisons from all the fortified places; and then turned against the Berbers, who when they were ultimately subdued henceforward remained faithful to the Arabs.

In the meantime 'Abdalmalik reconstituted the administration of the empire on Arabic principles. Up to the year 693 the Muslims had no special coinage of their own, and chiefly used Byzantine and Persian money, either imported or struck by themselves. 'Abdalmalik instituted a purely Islamic coinage. A still greater innovation was that Arabic became the official language of the State. In the conquered countries till then, not only had the Greek and Persian administration been preserved, but Greek remained the official language in the western, Persian in the eastern provinces. All officials were now compelled to know Arabic and to conduct their administration in that language. Lastly, a regular post service was instituted from Damascus to the provincial capitals, especially destined for governmental dispatches. The postmasters were charged with the task of informing the caliph of all important news in their respective countries.

'Abdalmalik died on Oct. 9, 705, at the age of about sixty. His reign was one of the most stormy in the annals of Islam, but also one of the most glorious; he not only brought triumph to the cause of the Umayyads, but also extended and strengthened the Muslim power as a whole.

6. **Reign of Walid I.**—This is the most glorious epoch in the history of Islam. In Asia Minor and Armenia, Walid's generals obtained numerous successes against the Greeks, and in Armenia advanced even as far as the Caucasus. In Africa, Mūsā in a short time carried his conquests as far as Fez, Tangier and Ceuta, and one of his captains even made a descent on Sicily and plundered Syracuse. When he returned from the west to Kairawān, he made his client Tāriq governor of Tangier and of the whole western part of Africa. In the beginning of A.D. 711, Tāriq passed over into Spain with an army composed mainly of Berbers. The spot where he landed thence acquired the name of Jabal Tāriq, "Mountain of Tāriq," afterwards corrupted into Gibraltar. Having made himself master of Algeciras and thereby secured his communication with Africa, Tāriq set out at once in the direction of Cordova, and after a brilliant campaign, in 712, proclaimed the caliph of Damascus as sole ruler of the whole peninsula.

In the East the Muslim armies gained the most astonishing successes. In the course of a few years Qutaybah b. Muslim conquered Paikand, Bokhara, Samarkand, Khwarizm (modern Khiva), Ferghana and Shāsh (Tashkent), and even Kashgar on the frontiers of China. Meanwhile Muḥammad b. Qāsim invaded Makran, took Daibal, passed the Indus, and marched, after having beaten the Indian king, Dahar, through Sind upon Multān, which he conquered and whence he carried off an immense booty.

Towards the end of this reign, died Ḥajjāj, the great viceroy of the Orient. He was a man of extraordinary ability, and accomplished the task committed to him with vigour and energy. To his unflinching constancy was due the suppression of the dangerous rebellion of Ibn Ash'ath. After the restoration of peace his capacity for organization was displayed in all directions. The draining and tilling of submerged or uncultivated land on a large scale, the promotion of agriculture in every way, in particular by the digging of channels, and the regulation of the system of taxation, were carried out on his initiative. He showed the utmost wisdom in the selection of his lieutenants. The fear of his name was so great that even in the desert there was security for life and property, and his brilliant military successes were unquestionably due in a great measure to the care which he bestowed on equipment and commissariat. The heavy expenses entailed thereby were largely met by the booty which he won.

7. **Reign of Sulaymān.**—Sulaymān succeeded on the death of his brother, Jumāda II. 96 (Feb. 715). Walīd had, in his last years made preparations against Constantinople. Sulaymān carried them on with energy, and as early as the autumn of A.D. 715 Maslama invaded Asia Minor at the head of a numerous army, whilst a well-equipped fleet sailed out to second him. The first year of the expedition was not unsuccessful. The siege of Amorium in Phrygia was broken up, but Pergamum and Sardis were taken. On Aug. 25, 716, the blockade of Constantinople began from the land side, and two weeks later from the sea side. The siege lasted about a year. The besieged were hard pressed, but the besiegers suffered by the severe winter, and were at last obliged to raise the siege. Maslama brought back the rest of his army in a pitiful state, while the fleet, on its return, was partly destroyed by a violent tempest. Maslama was still on his way back when Sulaymān died at Dābiq in northern Syria, which was the base of the expeditions into Asia Minor.

8. **Reign of 'Umar II.**—Sulaymān was succeeded by his devout cousin, 'Umar b. 'Abd al-'Azīz, who did his best to imitate his grandfather 'Umar in all things, and especially in maintaining the simple manner of life of the early Muslims. He was, however, born in the midst of wealth; thus frugality became asceticism, and in so far as he demanded the same rigour from his relatives, he grew unjust and caused uneasiness and discontent. In the matter of taxes, though actuated by the most noble designs, he did harm to the public revenues. The principle of Islam was, that no Muslim, whatever might be his nationality, should pay any tax other than the *zakāt* or poor-rate. (See ISLAMIC INSTITUTIONS.) In practice, this privilege was confined to the Arabic Muslims. 'Umar wished to maintain the principle. The original inhabitants had been left on the conquered lands as agriculturists, on condition of paying a fixed sum yearly for each district. If one of these adopted Islam, 'Umar permitted him to leave his place, which had been strictly forbidden by Ḥajjāj in 'Irāq and the eastern provinces, because by it many hands were withdrawn from the tilling of the ground, and those who remained were unable to pay the allotted amount. 'Umar's system not only diminished the actual revenue, but largely increased in the cities the numbers of the *maulā's* (clients), mainly Persians, who were weary of their dependency on their Arabic lords, and demanded equal rights for themselves. In north Africa particularly, and in Khurasan the effect of 'Umar's proclamation was that a great multitude embraced Islam. When it became necessary to impose a tribute upon the new converts, great discontent arose, which largely increased the number of those who followed the Shi'ite preachers of revolt. Conversion to Islam was promoted by the severe regulations which 'Umar introduced for the non-believers, such as Christians and Jews. It was he who issued those humiliating rescripts, which are commonly but unjustly attributed to 'Umar I. But he forbade extortion and suppressed more than one illegal impost. He followed the guidance of divines and devotees, in whose congenial company he delighted. It is, therefore, not to be wondered at that these men saw in 'Umar the ideal of a prince, and that in Muslim history he has acquired the reputation of a saint.

9. **Reign of Yazīd II.**—'Umar's reign was as short as that of his predecessor. He died on Feb. 9, 720. Yazīd II., son of 'Abdalmalik and, by his mother 'Ātika, grandson of Yazīd I., ascended the throne without opposition. He had at once, however, to put down a dangerous rebellion, which, commencing in Baṣra, spread to Ahwāz (Khūzistān), Fārs and Kirmān. As the rebellion threatened to spread far and wide, Yazīd II. was obliged to appeal to his brother, the celebrated Maslama, who with his Syrian troops completely defeated the rebels and ruthlessly hunted them to death.

Maslama was rewarded with the governorship of 'Irāq and Khurasan, but was soon replaced by Ibn Hubayra, who under 'Umar II. had been governor of Mesopotamia. He belonged to the tribe of Qays, and was very severe against the Azd and other Yemenite tribes, who had more or less favoured the rebellion. In these years the antagonism between Qays (Mudar) and Yemenites became more and more acute, especially in Khurasan, where Ibn

Hubayra caused large sums of money to be extorted from several of the most respectable Khurasanians. The discontent roused thereby became one of the principal causes of the fall of the Umayyads.

In Africa serious troubles arose from the same cause, when the governor issued orders that the villagers who, having adopted Islam, were freed from tribute according to the promise of 'Umar II., and had left their villages for the towns, should return to their domiciles and pay the same tribute as before their conversion. The Berbers rose in revolt, slaughtered the unfortunate governor, and put in his place the former governor. Yazīd II., died on Jan. 26, 724, according to the chroniclers, from grief for the loss of a favourite singing-girl. As his successor he had appointed in the first place his brother Hishām, and after him his own son Walīd.

10. **Reign of Hishām.**—Hishām was a wise and able prince and an enemy of luxury, not an idealist like 'Umar II., nor a worldling like Yazīd II., but more like his father 'Abdalmalik, devoting all his energy to the pacification of the interior, and to extending and consolidating the empire of Islam. But the discontent, which had been sown under his predecessors, had now developed to such an extent that he could not suppress it in detail.

In 'Irāq Zayd b. 'Alī, grandson of Ḥusayn b. 'Alī, who had come to Kūfa for a lawsuit, was persuaded by the chiefs of the Shi'a to organize a revolt in 740, but he was deserted by his troops and slain. His son Yaḥyā, still a youth, fled to Balkh in Khurasan, but was hunted down, till he fell, sword in hand, under Walīd II. Abū Muslim, the founder of the Abbasid dynasty, proclaimed himself his avenger, and on that occasion adopted the black garments, which remained the distinctive colour of the dynasty.

In Khurasan also there were very serious disturbances. The Sogdians implored the assistance of the Turks, who had long been contending earnestly against the Arabs for the dominion of Transoxiana. The Government troops suffered more than one defeat, but in 736 a brilliant victory over the Turks finally caused them to retreat. Hishām separated Khurasan from 'Irāq and chose as governor of the former Naṣr b. Sayyār, a valiant soldier who had grown grey in war. Naṣr instituted a system of taxation, which, if it had been introduced earlier, would perhaps have saved the Arabic domination. It was that which later on was generally adopted, viz., that all possessors of conquered lands (*i.e.*, nearly the whole empire except Arabia), whether Muslims or not, should pay a fixed tax, the latter in addition to pay a poll-tax, from which they were relieved on conversion to Islam. During the reign of Hishām, Naṣr made a successful expedition against the Turks. The propaganda of the Shi'a by the Abbasids was continued in these years with great zeal.

In India several provinces which had been converted to Islam under the Caliphate of 'Umar II. declared themselves independent, because the promise of equal rights for all Muslims was not kept under the reign of his successors. This led to the evacuation of the eastern part of India (called Hind by the Arabs, Sind being the name of the western part), and to the founding of the strong cities of Maḥfūza and Manṣūra for the purpose of controlling the land.

In the north and north-west of the empire there were no internal disorders, but the Muslims had hard work to maintain themselves against the Alans and the Khazars. The war against the Byzantines was continued with energy during the whole of Hishām's reign.

In Africa the hand of government pressed heavily. The Berbers, though they had pledged themselves to Islam and had furnished the latest contingents for the Holy War, were treated as tributary serfs. The Kharijites, of whom a great many had emigrated to Africa, found them eager listeners, and a fierce insurrection broke out which was not easily suppressed.

Hishām died in Feb. 743, after a reign of 20 years. He had not been wanting in energy and ability, and kept the reins of the government in his own hands. His financial administration was sound and he guarded against any misuse of the revenues of

the State. But he was not popular. Hishām tried to keep himself free from and above the rival parties, but his vicereagents were inexorable. Notwithstanding his activity and his devotion to the management of affairs, the Muslim power declined rather than advanced, and signs of the decay of the Umayyad dynasty began to show themselves. The history of his four successors, Walid II., Yazid III., Ibrāhīm and Marwān II., is but the history of the fall of the Umayyads.

11. **Reign of Walid II.**—Walid II. was a handsome man, possessed of extraordinary physical strength, and a distinguished poet. His first public action was to increase the pay of all soldiers by 10 dirhems, that of the Syrians by 20. The Umayyads who came to pay their respects to him received large donations.

But he made the mistake of designating his two sons as heirs to the Caliphate. These were still under age and were not the children of a free-born, noble mother. A conspiracy arose, headed by Yazid b. Walid I., and joined by the majority of the Marwanid princes and many Kalbites and other Yemenites. The conspirators met with slight opposition. Without difficulty, Yazid made himself master of Damascus, and the caliph was murdered on April 17, 744.

12. **Reign of Yazid III.**—Yazid III., on his accession, made a fine speech, in which he promised to do all that could be expected from a good and wise ruler, even offering to make place immediately for the man whom his subjects should find better qualified for the Caliphate than himself. But the distant provinces, with the exception of Sind and Sijistan, renounced his authority. In Africa ‘Abdarrahman b. Ḥabīb was almost independent. In Spain every amir tried to free himself from a suzerainty which appeared to him only nominal. Naṣr b. Sayyār, the governor of Khurasan, had not yet decided whether he ought to take the oath of allegiance when Yazid died, after a reign of only five months and a half in 744.

13. **Yazid III.** left his brother Ibrāhīm as his successor. He was acknowledged as caliph only in a part of Syria, and reigned no longer than two months, when he was obliged to abdicate and to submit to the authority of Marwān II.

14. **Marwan II.**, the son of Muḥammad b. Marwān and cousin of Maslama, was a man of energy, and might have revived the strength of the Umayyad dynasty, but for the general disorder which pervaded the whole empire. Marwān did all he could to pacify Syria, permitting the Arabs of the four provinces to choose their own prefects. He did not, however, wish to reside in Damascus, but transplanted the seat of government to his own town, Harran in Mesopotamia.

But the pacification was only on the surface. Many Umayyad princes considered Marwān as an upstart, his mother being a slave-girl; the Damascenes were angry because he had chosen Harran for his residence; the Kalbites felt themselves slighted, as the Qaisites predominated. Marwān, who wanted to march against ‘Irāq, was obliged to return to Syria, where he put an end to the troubles. Shortly afterwards Sulaymān b. Hishām persuaded the Syrians to proclaim him caliph. But Marwān utterly defeated him at Khosāf in the district of Kinnesrin, and then besieged his brother Sa‘id in Homs. After the victory the walls were demolished, and likewise those of Baalbek, Damascus, Jerusalem and other towns. Syria was utterly crushed, and therewith the bulwark of the dynasty was destroyed. Not until 746 could Marwān resume his campaign against ‘Irāq. Here the Kharijites had set up a rival caliph and had captured (in Aug. 745) Hira, the residence of the governor of the province.

Whilst Marwān besieged Homs, the Kharijite army, which now numbered 120,000 men, returned to Mesopotamia, took Mosul, and threatened Nisibis. Mesopotamia itself was in danger, when Marwān at last was able to march against the enemy. In a furious battle at Kafartūtha (Sept. A.D. 746) the Kharijites were defeated; and their rebellion was crushed during the campaign of the following year. Thus, at last, the western and south-eastern parts of the empire lay at the feet of Marwān. But in the north-east, in Khurasan, meanwhile a storm had arisen, against which his resources and his wisdom were alike of no avail.

When the news of the murder of Walid II. reached Khurasan,

Naṣr b. Sayyār did not at once acknowledge the Caliphate of Yazid III., but induced the Arab chiefs to accept himself as amir of Khurasan, until a caliph should be universally acknowledged. But Naṣr had a personal enemy, the chief of the Azd (Yemenites), Kirmānī, a very ambitious man. A quarrel arose, and in a short time the Azd under Kirmānī, supported by the Rabi‘a, who always were ready to join the opposition, were in insurrection; Naṣr tried in vain to put it down by concessions, and finding that he could hold Merv no longer, retired to Nishapur.

Since the days of ‘Alī there had been two tendencies among the Shi‘ites. The moderate party distinguished itself from the other Muslims only by its doctrine that the imamate belonged legally to a man of the House of the Prophet. The other party, that of the ultra-Shi‘ites, named Hashimiya after Abū Ḥāshim, the son of Muḥammad b. al-Ḥanafiya, preached the equality of all Muslims, Arabs or non-Arabs, and taught that the same divine spirit that had animated the Prophet incorporated itself again in his heirs. After the death of Ḥusayn, they chose for their Imām Muḥammad b. al-Ḥanafiya, and at his decease his son, Abū Ḥāshim, from whom Muḥammad b. ‘Alī, the grandson of ‘Abdallah b. ‘Abbās, who resided at Ḥomaima in the south-east of Syria, obtained the secrets of the party and took the lead. This Muḥammad, the father of the two first Abbasid caliphs, was a man of unusual ability and great ambition. He directed his energies primarily to Khurasan. The missionaries were charged with the task of undermining the authority of the Umayyads, by drawing attention to all the injustices that took place under their reign, and to all the luxury and wantonness of the court, as contrasted with the misery of many of their subjects. God would not suffer it any longer. As soon as the time was ripe He would send a saviour out of the House of the Prophet, the Mahdī, who would restore Islam to its original purity. The missionaries had great success, especially among the non-Arabic inhabitants of Khurasan and Transoxiana.

When Muḥammad b. ‘Alī died, his son Ibrāhīm, the Imām, took his place. Ibrāhīm had a confidant about whose antecedents one fact alone seems certain, that he was a *maulā* (client) of Persian origin. This man, Abū Muslim by name, was a man of real ability and devoted to his master's cause. To him, in 745-746, the management of affairs in Khurasan was entrusted. At first the chiefs of the mission were by no means prepared to recognize Abū Muslim as the plenipotentiary of the heir of the Prophet. In the year 749 he judged that the time for open manifestation had arrived. His partisans were ordered to assemble from all sides on a fixed day at Siqadanj in the province of Merv. Then, on June 15, 747, the first solemn meeting took place and the black flags were unfolded. By the end of the year Abū Muslim, whom the majority believed to belong himself to the family of the Prophet, was the acknowledged head of a strong army. Meantime, Naṣr had moved from Nishapur to Merv, and here the two Arabic armies confronted each other. Then, at last, the true significance of Abū Muslim's work was recognized. Naṣr warned the Arabs against their common enemy, "who preaches a religion that does not come from the Envoy of God, and whose chief aim is the extirpation of the Arabs." In vain he had entreated Marwān to send him troops before it should be too late. When at last it was possible to them to fulfil his wish, it was, in fact, too late. But Abū Muslim made himself master of Merv, in Dec. 747. Naṣr escaped only by a headlong flight to Nishapur. This was the end of the Arabic dominion in the East.

As soon as Abū Muslim had consolidated his authority, he sent his chief general, Qaḥṭaba, against Nishapur. Naṣr could not further resist. He reached Sāwā in the vicinity of Hamadan, where he died quite exhausted, at the age of 85 years. Rayy and Hamadan were taken without serious difficulty. In June 749 Nihāwand surrendered, and thereby the way to ‘Irāq lay open to Qaḥṭaba. Qaḥṭaba himself perished in the combat, but his son Ḥasan entered Kūfa without any resistance on Sept. 2, 749.

Marwān had at last discovered who was the real chief of the movement in Khurasan, and had seized upon Ibrāhīm the Imām and imprisoned him at Harran. There he died, probably from the plague, though Marwān was accused of having killed him.

The other Abbasids arrived at Kūfa in the latter half of Sept. 749, where in the meantime the head of the propaganda, Abū Salama, had previously undertaken the government. This Abū Salama seems to have had scruples against recognizing Abu'l-'Abbās as the successor of his brother Ibrāhīm, and to have expected that the Mahdī, whom he looked for from Medina, would not be slow in making his appearance, little thinking that an Abbasid would present himself as such. But Abū Jahm, on the instructions of Abū Muslim, declared to the chief officers of the Khurasanian army that the Mahdī was in their midst, and brought them to Abu'l-'Abbās, to whom they swore allegiance. Abū Salama also was constrained to take the oath. On Nov. 28, 749, Abu'l-'Abbās was solemnly proclaimed caliph in the principal mosque of Kūfa. The trick had been carried out admirably. On the point of gathering the ripe fruit, the Alids were suddenly pushed aside, and the fruit was snatched away by the Abbasids. The latter gained the throne and they took good care never to be deprived of it.

The advancing Abbasid army completely defeated Marwān near the Greater Zab, an affluent of the Tigris, in a battle which lasted 11 days. Marwān retreated to Harran, thence to Damascus, and finally to Egypt, where he fell in a last struggle (Aug. 750). His head was cut off and sent to Kūfa. In Syria, the Umayyads were persecuted with the utmost rigour. Even their graves were violated, and the bodies crucified and destroyed. Only a few Umayyads escaped the massacre. A grandson of Hishām, 'Abdarrahmān, reached Africa and founded in Spain the Umayyad dynasty of Cordova.

With the dynasty of the Umayyads the hegemony passes finally from Syria to 'Irāq. At the same time the supremacy of the Arabs came to an end. Thenceforth it is not the contingents of the Arabic tribes which compose the army, and on whom the Government depends; the new dynasty relies on a standing army, consisting for the greater part of non-Arabic soldiers. The barrier that separated the Arabs from the conquered nations begins to crumble away. Only the Arabic religion, the Arabic language, and the Arabic civilization maintain themselves, and spread more and more over the whole empire.

### C.—THE ABBASID CALIPHS

We now enter upon the history of the new dynasty, under which the power of Islam reached its highest point.

1. **Abu'l-'Abbās** inaugurated his Caliphate by a harangue to the people of Kūfa, in which he announced the era of concord and happiness which was to begin now that the House of the Prophet had been restored to its right. He asserted that the Abbasids were the real heirs of the Prophet, as the descendants of his oldest uncle 'Abbās. He did not, however, trust the Kufians. He resided outside the town with the Khurasanian troops, and with them went first to Hira, then to Hāshimiya, which he caused to be built in the neighbourhood of Anbar.

The ruin of the Umayyad empire and the rise of the new dynasty did not take place without mighty convulsions. In Bathaniya and the Ḥaurān, in the north of Syria, in Mesopotamia and 'Irāq Khurasan insurrections had to be put down with fire and sword. The new caliph then distributed the provinces among the principal members of his family and his generals. Africa and Spain are omitted from this catalogue, because the Abbasids never gained any real footing in Spain, while Africa remained, at least in the first years, in only nominal subjection to the new dynasty. In 754 Abū Muslim came to 'Irāq to visit Abu'l-'Abbās and was received with great honour.

Abu'l-'Abbās died on June 5, 754. He seems to have been a man of limited capacity, and had very little share in the achievements accomplished in his name. In the few cases where he had to decide, he acted under the influence of his brother Abū Ja'far.

2. **Reign of Mansur.**—Abu'l-'Abbās had designated as his successors first Abū Ja'far, surnamed al-Manṣūr (the victorious), and after him his cousin 'Isā b. Mūsā.

The first care of Manṣūr was now to get rid of the powerful Abū Muslim. On pretence of conferring with him on important business of state, Manṣūr induced him to come to Madāin (Ctesiphon), and in the most perfidious manner caused him to be

murdered by his guards.

About the same time Africa and Spain escaped from the dominion of the eastern Caliphate; the former for a season, the latter permanently. But in the year 761 Muḥammad b. Ash'ath, the Abbasid general, entered Kairawan and regained possession of Africa in the name of the eastern caliph. From the year 800, it must be added, Africa only nominally belonged to the Abbasids; for, under the reign of Hārūn al-Rashīd, Ibrāhīm b. al-Aghlab, who was invested with the government of Africa, founded in that province a distinct dynasty, that of the Aghlabites.

At the same time as the revolt in Africa, the independent Caliphate of the western Umayyads was founded in Spain by one of the last survivors of the Umayyads, 'Abdarrahmān b. Mu'āwiyah, grandson of the caliph Hishām. (*See SPAIN: History.*)

While Manṣūr was thus losing Africa and Spain, he was trying to redeem the losses which the Byzantines had inflicted on the empire on the northern frontier. But from 758 till 763 Manṣūr was so occupied with his own affairs that he could not think of further raids.

In 758 (others say in 753 or 754) a body of 600 sectaries, called the Rāwandīs, went to Hāshimiya, the residence of the caliph, and began to pay him divine honours. These fanatics, having later risen in revolt, were hunted down and massacred to the last man, and thereby the ties that bound the Abbasids to the ultra-Shi'ites were severed. From that time forward the Abbasid caliphs became the maintainers of orthodox Islam, just as the Umayyads had been.

A much greater danger now threatened Manṣūr. In the last days of the Umayyads, the Shi'ites had chosen as caliph, Muḥammad b. 'Abdallāh b. Ḥasan, whom they called the Mahdī, and Manṣūr had been among those who pledged themselves to him by oath. Not unnaturally, the Alids in Medina were indignant at being supplanted by the Abbasids, and Manṣūr's chief concern was to get Muḥammad into his power. In 758 Manṣūr, informed that a revolt was in preparation, came himself to Medina and ordered 'Abdallāh to tell him where his sons were. As he could not or would not tell, he together with all his brothers and some other relatives were seized and transported to 'Irāq where 'Abdallāh and his brother 'Alī were beheaded and the others imprisoned. Notwithstanding all these precautions, a vast conspiracy was formed. In 762 Muḥammad took Medina and had himself proclaimed caliph, but was defeated and slain. In the meanwhile Ibrāhīm had not only gained possession of Baṣra, Ahwāz and Fārs, but had even occupied Wāsit. The empire of the Abbasids was in great jeopardy. Had Ibrāhīm marched at once against Kūfa he might have crushed Manṣūr, but he let slip the opportunity. A terrible conflict took place at Bā-Khamra, 48m. from Kūfa, and Ibrāhīm was finally defeated. His head was cut off and brought to Manṣūr.

Manṣūr could now give his mind to the founding of the new capital. He made choice of the admirable site of the old market-town of Baghdad on the western bank of the Tigris. Strictly it was a huge citadel, in the centre of which was the palace of the caliph and the great mosque. But around this nucleus there soon grew up the great metropolis which was to be the centre of the civilized world as long as the Caliphate lasted. The building lasted three years and was completed in the year 766.

'Isā b. Mūsā had been designated, as we have seen, by Abu'l-'Abbās as successor to Manṣūr. The latter having vainly tried to compel 'Isā to renounce his right of succession, in favour of Manṣūr's son, Muḥammad al-Mahdī, produced false witnesses who swore that he had done so. However unwillingly, 'Isā was obliged at last to yield. One of the false witnesses was, it is asserted, Khālid b. Barmak, the head of that celebrated family, the Barmecides (*q.v.*), who played so important a part in the reign of Hārūn al-Rashīd. This Khālid, who was descended from an old sacerdotal family in Balkh, and had been one of the trusty supporters of Abū Muslim, Manṣūr appointed as minister of finance.

In 775 Manṣūr died after having reigned for 22 years. He was a man of rare energy and strength of mind. His ambition was boundless and no means, however perfidious, was despised by him. But he was a great statesman and knew how to choose able officers for all places.

3. **Reign of Mahdī.**—As soon as Maṣṣūr was dead, Rabī', his client and chamberlain, induced all the princes and generals who accompanied the caliph, to take the oath of allegiance to his son Muḥammad al-Mahdī, who was then at Baghdad. In 161, Mahdī was menaced by a dangerous revolt, led by a sectary, known generally as Muqanna' (*q.v.*), or "the veiled one," because he always appeared in public wearing a mask. He took up his abode in the Transoxianian province of Kish and Nakhshab, where he gathered around him a great number of adherents. After some successes, the pretender was ultimately cornered at the castle of Sanām near Kish, and took poison together with all the members of his family. His head was cut off and sent to Mahdī.

During the reign of Maṣṣūr the annual raids against the Byzantines had taken place almost without intermission, but the only feat of importance had been the conquest of Laodicea, called "the burnt" (*ἡ κατακεκαυμένη*) by Ma'yūf b. Yahyā in the year 770. At first the armies of Mahdī were not successful. The Greeks even conquered Marash (Germanicia) and annihilated the Muslim army sent from Dābiq. In 778, however, Ḥasan b. Qaṭṭaba made a victorious raid as far as Adhrūliya (Dorylaeum); it was on his proposition that Mahdī resolved on building the frontier town called Ḥadath (Adata), which became an outpost. In 779 the caliph decided on leading his army in person. Traversing Mesopotamia and Syria, he entered Cilicia, and established himself on the banks of the Jihan (Pyramus). Thence he despatched an expeditionary force, nominally under the command of Hārūn, but in reality under that of his tutor, the Barmecide Yahyā b. Khālīd. Hārūn captured the fortress Samālu after a siege of 38 days. In consequence of this feat, Mahdī made Hārūn governor of the whole western part of the empire, including Azerbaijan and Armenia. Two years later war broke out afresh between the Muslims and the Greeks. The Muslims invaded Cilicia under the orders of 'Abdalkabīr who, being afraid of encountering the enemy, retired with his troops. Irritated by this failure, the caliph in 781 sent Hārūn, accompanied by his chamberlain Rabī', with an army of nearly 100,000 men, with orders to carry the war to the very gates of Constantinople. Hārūn marched against Nicomedia, where he vanquished the domesticus, the chief commander of the Greek forces, and pitched his camp on the shores of the Bosphorus. The regent, Irene, sued for peace, and obtained a truce for three years, but only on the humiliating terms of paying an annual tribute of 90,000 denarii, and supplying the Muslims with guides and markets on their way home. This brilliant success so increased Mahdī's affection for Hārūn that he appointed him successor-designate after Mūsā and named him *al-Rashīd* ("the follower of the right cause"). Three years later, he died suddenly, at the age of only 43.

The reign of Mahdī was a time of great prosperity. Much was done for the organization of the huge empire; agriculture and commerce flourished; the revenues were increasing, whilst the people fared well. The power of the State was acknowledged even in the Far East: the emperor of China, the king of Tibet, and many Indian princes concluded treaties with the caliph. He was an ardent champion of the orthodox faith, and persecuted mercilessly the Manichaeans and all kinds of freethinkers.

4. **Reign of Hādī.**—On the death of Mahdī, Hārūn, following the advice of Yahyā b. Khālīd, sent the insignia of the Caliphate, with letters of condolence and congratulation, to Mūsā and brought the army which had accompanied Mahdī peacefully back from Media to Baghdad. Mūsā returned in all haste to the capital, and assumed the title of *al-Hādī* ("he who directs").

Hādī, who had never been able to forget that he had narrowly escaped being supplanted by his brother, formed a plan for excluding him from the Caliphate and transmitting the succession to his own son Ja'far. To this he obtained the assent of his ministers and the principal chiefs of his army, with the exception of Yahyā b. Khālīd, Hārūn's former tutor, who showed such firmness and boldness that Hādī cast him into prison and resolved on his death. Some historians say that he had already given orders for his execution, when he himself was killed (Sept. 14, 786) by his mother Khaizurān, who had systematically and successfully intrigued against him with the object of gaining the real power for herself.

5. **Reign of Hārūn al-Rashīd.**—Hārūn ascended the throne without opposition. His first act was to choose as prime minister his former tutor, the faithful Yahyā b. Khālīd, and to confide important posts to the two sons of Yahyā, Faḍl and Ja'far, of whom the former was his own foster-brother, the latter his intimate friend. Loaded with all the burdens of government, Yahyā brought the most distinguished abilities to the exercise of his office. He put the frontiers in a good state of defence; he filled the public Treasury, and carried the splendour of the throne to the highest point. His sons, especially Faḍl, were worthy of their father.

Although the administration of Hārūn's States was committed to skilful hands, yet the first years of his long reign were not free from troubles. Towards the year 793 a man of the house of 'Alī, named Yahyā b. 'Abdallāh, another brother of Muḥammad and Ibrāhīm, publicly claimed the Caliphate, but he was induced to submit by a promise of safety and a brilliant position at the court of Baghdad. At the end of some months, however, he was calumniously accused of conspiracy, and the caliph, seizing the opportunity of ridding himself of a possible rival, threw him into prison, where he died, according to the majority of the historians, of starvation. Others say that Ja'far b. Yahyā b. Khālīd, to whose care he had been entrusted, suffered him to escape, and that this was the real cause of Hārūn's anger against the Barmecides (*q.v.*). Dreading fresh insurrections of the Alids, Hārūn secured the person of another descendant of 'Alī, Mūsā b. Ja'far, surnamed al-Kāzīm, who enjoyed great consideration at Medina, and had already been arrested and released again by Mahdī. The unfortunate man was brought by the caliph himself to Baghdad and there died, apparently by poison.

Meanwhile Hārūn did not forget the hereditary enemy of Islam. Almost every year successful raids were made into Asia Minor, in the year 797 under the command of the caliph himself, so that Irene was compelled to sue for peace. Even in the midst of the cares of war, Hārūn was assiduous in his religious duties, and few years passed without his making the pilgrimage.

It was in the beginning of the following year, at the very moment when the Barmecides thought their position most secure, that Hārūn brought sudden ruin upon them. The causes of their disgrace have been differently stated by the annalists. (*See BARMECIDES.*) The principal cause appears to have been that they abused the sovereign power which they exercised. Not a few were jealous of their greatness and sought for opportunities of instilling distrust against them into the mind of Hārūn, and of making him feel that he was caliph only in name. The secret dissatisfaction thus aroused was increased, according to some apparently well-informed authorities, by the releasing of the Alid Yahyā b. 'Abdallāh, already mentioned. Finally Hārūn resolved on their destruction, and Ja'far b. Yahyā was arrested and beheaded. The following day, his father Yahyā, his brother Faḍl, and all the other Barmecides were arrested and imprisoned; all their property was confiscated. The only Barmecide who remained unmolested with his family was Muḥammad the brother of Yahyā, who had been the chamberlain of the caliph till 795, when Faḍl b. Rabī' got his place. This latter had henceforward the greatest influence at court.

In the same year hostilities broke out again with the Greeks, and the new emperor, Nicephorus, was so completely beaten that he was compelled to submit to very harsh conditions.

The disturbances in Khurasan were caused by the malversations of the governor of that province, 'Alī b. 'Isa b. Māhān. The caliph went in person to Merv, in order to judge of the reality of the complaints which had reached him, but confirmed 'Alī in his post, and, after having received the chiefs of Tabaristān who came to tender their submission, returned through Baghdad to Rakka on the Euphrates, which city was his habitual residence. In the following year Rāfi' b. Layth, a grandson of Naṣr b. Sayyār, raised the standard of revolt in Samarkand. The caliph's hope that Rāfi' would submit on condition of receiving a free pardon was not fulfilled, and he resolved to set out himself to Khurasan, taking with him his second son Ma'mūn. On the journey he was attacked by an internal malady, from which he died, ten months

after his departure from Baghdad in March 809, just on his arrival at the city of Tūs. Hārūn was only 45 years of age. As long as the Barmecides were in office, he acted only on their direction. After their disgrace he was led into many impolitic actions by his violent and often cruel propensities. But the empire was, especially in the earlier part of his reign, in a very prosperous state, and was respected widely by foreign Powers. Embassies passed between Charlemagne and Hārūn in the years 797 and 801, by which the former obtained facilities for the pilgrims to the Holy Land, the latter probably concessions for the trade on the Mediterranean ports.

Under the reign of Hārūn, Ibrāhīm b. al-Aghlab, the governor of Africa, succeeded in making himself independent of the Central Government, on condition of paying a fixed annual tribute to his suzerain the caliph. This was, if we do not take Spain into account, the first instance of dismemberment, later to be followed by many others.

**6. Reign of Amīn.**—On the death of Hārūn his minister, Faḍl b. Rabi', with the view of gaining the new caliph's confidence, hastened to call together all the troops of the late caliph and to lead them back to Baghdad, in order to place them in the hands of the new sovereign, Amīn. War soon broke out between the two brothers, and their respective armies met under the walls of Rayy (May 811), where Ma'mūn's general Ṭāhir gained a brilliant victory. Ma'mūn now no longer hesitated to take the title of caliph.

Ṭāhir continued his victorious march and one after the other the provinces fell away from Amīn, and he soon found himself in possession of Baghdad alone. The city, though blockaded on every side, made a desperate defence for nearly two years. Ultimately the eastern part of the city fell into the hands of Ṭāhir, and Amīn, deserted by his followers, was compelled to surrender and was put to death. His head was sent to Ma'mūn (Sept. 813). Amīn was only 28 years old. As a ruler he was wholly incompetent, and the five years of his reign were disastrous to the empire, and in particular to Baghdad, which never entirely recovered its old splendour.

**7. Reign of Ma'mūn.**—On the day following the death of Amīn, Ṭāhir caused Ma'mūn to be proclaimed at Baghdad, and promised in his name a general amnesty. The accession of this prince appeared likely to restore to the empire the order necessary for its prosperity. It was not so, however. The reign of Ma'mūn had a very stormy beginning; he was in no haste to remove to Baghdad, but continued to reside at Merv. The Alids seized on his elevation as a pretext for fresh revolts, and Mecca, Medina and Yemen fell into their hands, and several cities of 'Irāq were occupied by rebels, but at last the tide of disaster was checked. The troops of the Alids were everywhere driven back, and the whole of 'Irāq fell again into the hands of the Abbasids, and peace seemed within reach. This, however, was by no means the case. The disorder of civil war had caused a multitude of robbers and vagabonds to emerge from the purlieus of Baghdad. These ruffians proceeded to treat the capital as a conquered city, and it became necessary for all good citizens to organize themselves into a regular militia.

Meanwhile, at Merv, Ma'mūn was adopting a decision which fell like a thunderbolt on the Abbasids. In 817 under pretence of putting an end to the continual revolts of the partisans of 'Alī, he publicly designated as his successor in the Caliphate 'Alī ar-Riḍā, a son of that Mūsā al-Kāzīm who perished in the prison of Mahdī. The people of Baghdad refused to take the oath to 'Alī b. Mūsā, declared Ma'mūn deposed, and elected his uncle, Ibrāhīm, son of Mahdī, to the Caliphate. Ma'mūn was much incensed and wrote that he was coming to Baghdad in a short time. From that moment the pseudo-caliph Ibrāhīm found himself deserted, and was obliged to seek safety in concealment. His precarious reign had, however, lasted nearly two years. Having taken all precautions, Ma'mūn now made his solemn entry into Baghdad in Aug. 819.

When welcoming Ṭāhir, Ma'mūn bade him ask for any reward he might desire. Ṭāhir, fearing lest the caliph, not being able to endure the sight of the murderer of his brother, should change

his mind towards him, contrived to get himself appointed governor of Khurasan. Like most of the great Muslim generals, Ṭāhir, it is said, had conceived the project of creating an independent kingdom for himself. His death (A.D. 822), prevented its realization; but as his descendants succeeded him one after the other in the post of governor, he may be said in reality to have founded a dynasty in Khurasan.

The pseudo-caliph, Ibrāhīm was eventually arrested, but Ma'mūn generously pardoned him.

Tranquillity being now everywhere re-established, Ma'mūn gave himself up to science and literature. He caused works on mathematics, astronomy, medicine and philosophy to be translated from the Greek, and founded in Baghdad a kind of academy, called the "House of Science," with a library and an observatory. Ma'mūn interested himself, too, in questions of religious dogma. He had embraced the Mu'tazilite doctrine about free will and predestination, and in 827 he published an edict by which the Mu'tazilite doctrine was declared to be the religion of the State, the orthodox faith condemned as heretical. At the same time he ordered all his subjects to honour 'Alī as the best creature of God after the Prophet, and forbade the praise of Mu'āwiyah. In 833 a new edict appeared by which all judges and doctors were summoned to renounce the error of the uncreated word of God. In the reign of Mutawakkil the orthodox faith was restored, never to be assailed again.

In spite of these manifold activities Ma'mūn did not forget the hereditary enemy of Islam. In the years 830, 831 and 832 he made expeditions into Asia Minor with such success that Theophilus, the Greek emperor, sued for peace, which Ma'mūn haughtily refused to grant. Accordingly, he decided on marching in the following year against Amorium, and thence to Constantinople itself. He set out for Asia Minor to put himself at the head of the army, but died of a fever brought on by bathing in the chill river, Pedendon, 40m. from Tarsus, in Aug. 833, at the age of forty-eight.

Ma'mūn was a man of rare qualities, and one of the best rulers of the whole dynasty after Maṣṣūr. By him the ascendancy of the Persian element over the Arabian was completed. Moreover, he began to attract young Turkish noblemen to his court, an example which was followed on a much larger scale by his successor and led to the supremacy of the Turks at a later period.

**8. Reign of Mu'tasim.**—Abū Ishāq al-Mu'tasim had for a long time been preparing himself for the succession. Every year he had bought Turkish slaves, and had with him in the last expedition of Ma'mūn a bodyguard of 3,000. Backed by this force he seems to have persuaded the ailing caliph to designate him as his successor. He made his public entry into Baghdad on Sept. 20, 833.

Mu'tasim wanted officers for his bodyguard. Immediately after his coming to Baghdad, he bought all the Turkish slaves living there who had distinguished themselves. But the excesses of his Turkish soldiery so stirred up the anger of the inhabitants of Baghdad, that he resolved to move the capital, and having bought in 834 territories at Sāmarrā, a small place situated a few leagues above Baghdad, he established himself there in 836. This resolution of Mu'tasim was destined to prove fatal to his dynasty; for it placed the caliphs at the mercy of their praetorians. In fact, from the time of his son, Wāthiq, the Caliphate became the plaything of the Turkish guard, and its decline was continuous.

Mu'tasim was faced with the difficult task of suppressing the revolt of Bābak al-Khurramī in Azarbaijan. The Khurrami were not really Muslims, but Persian Mazdaqites, or communists. Their object was to abolish Islam and to restore "the white religion." During the civil war their power was steadily increasing, and spread not only over Azarbaijan, but also over Media (Jabal) and Khurasan. The numerous efforts of Ma'mūn to put them down had been all in vain, and they were now in alliance with the Byzantine emperor. Therefore, in the year 835, Mu'tasim made Afshīn, a Turkish prince, governor of Media, with orders to take the lead of the war against Bābak. After three years' fighting, Bābak was taken prisoner, carried to Sāmarrā, and put to death.

In the hope of creating a diversion in Bābak's favour, Theophilus in 837 fell upon and laid waste the frontier town of Zibatra. There and in several other places he took a great number of prisoners, whom he mutilated. The news arrived just after that of the capture of Bābak, and Mu'tasim swore to take exemplary vengeance. He assembled a formidable army, penetrated into Asia Minor, and took the city of Amorium, where he gained rich plunder.

Mu'tasim had just returned to Sāmarrā when a serious revolt broke out in Tabaristān, which was suppressed with great difficulty. Mu'tasim died a year later, in Jan. 842.

9. **Reign of Wāthiq.**—His son Wāthiq, who succeeded, though not in the least to be compared with Ma'mūn, had yet in common with him a thirst for knowledge and an intolerant adherence to the doctrine of the created Qur'ān. He carried his zeal to such a point that, on the occasion of an exchange of Greek against Muslim prisoners in 845, he refused to receive those Muslim captives who would not declare their belief that the Qur'ān was created. The only other event of importance in the reign of Wāthiq was a rising of the Arabian tribes in the environs of Medina, which the Turkish general, Boghā, with difficulty repressed. When he reached Sāmarrā with his prisoners, Wāthiq had just died (Aug. 846). That the predominance of the praetorians was already established is clear from the fact that Wāthiq gave to two Turkish generals, Ashnās and Itākh respectively, the titular but lucrative supreme government of all the western and all the eastern provinces. In his days the soldiery at Sāmarrā was increased by a large division of Africans (Maghribis).

10. **Reign of Mutawakkil.**—Wāthiq was succeeded by his brother Ja'far, who at his installation adopted the name of *al-Mutawakkil 'ala'llāh* ("he who trusts in God").

One of the first acts of Mutawakkil was the release of all those who had been imprisoned for refusing to admit the dogma of the created Qur'ān, which was declared heresy; therewith began a persecution of all the adherents of that doctrine and other Mu'tazilite tenets. Orthodoxy triumphed, never again to lose its place as the State religion. Hand in hand with these reactionary measures came two others, one against Jews and Christians, one against the Shi'ites. Mutawakkil, in 850, formulated an edict by which these sectaries were compelled to wear a distinctive dress and to distinguish their houses by a figure of the devil nailed to the door, excluding them at the same time from all public employments, and forbidding them to send their children to Muslim schools. He showed his hatred for the Shi'ites by causing the mausoleum erected over the tomb of Ḥusayn at Karbala, together with all the buildings surrounding it, to be levelled to the ground and the site to be ploughed up, and by forbidding anyone to visit the spot.

In the year 848–849 a revolt broke out in Azerbaijan and another, in 851–852, in Armenia. The annual raids of Muslims and Greeks in the border districts of Asia Minor were attended with alternate successes, though on the whole the Greeks had the upper hand. In 856 they penetrated as far as Amid (Diyārbakr), and returned with 10,000 prisoners. But in the year 859 the Greeks suffered a heavy defeat with losses of men and cattle, the emperor, Michael, himself was in danger, whilst the fleet of the Muslims captured and sacked Antalia. This was followed by a truce and an exchange of prisoners in the following year.

In 855 a revolt broke out in Homs (Emesa), where the harsh conditions imposed by the caliph on the Christians and Jews had caused great discontent. It was repressed after a vigorous resistance. A great many leading men were flogged to death, all churches and synagogues were destroyed and all the Christians banished.

About this time Sijistan liberated itself from the supremacy of the Tāhirids. Ya'qūb b. Layth al-Saffār proclaimed himself amīr of that province in the year 860, and was soon after confirmed in this dignity by the caliph.

In 858 Mutawakkil, hoping to escape from the arrogant patronage of the Turkish guard, contrived to enrol in his service nearly 12,000 men, for the greater part Arabs, in order to crush the Turks. The day had been fixed on which Muntaṣir, Waṣif and

several other Turkish generals were to be assassinated. But Waṣif and Muntaṣir had been informed, and resolved to anticipate him. In the night before Dec. 10, 861, Mutawakkil was murdered.

11. **Reign of Muntaṣir.**—On the very night of his father's assassination Muntaṣir had himself proclaimed caliph. He was a man of very feeble character, and a mere puppet in the hands of his vizier and the Turkish generals. He died six months after, by poison, it is said.

12. **Reign of Musta'in.**—The Turkish soldiery, now the chief power in the State, chose in succession to Muntaṣir, his cousin, Aḥmad, who took the title of *al-Musta'in billāh* ("he who looks for help to God"). In the reign of this feeble prince the Greeks inflicted serious losses on the Muslims in Asia Minor. In 865 the caliph's brother, Mu'tazz, was proclaimed caliph at Sāmarrā. A terrible war ensued; Musta'in was obliged to abdicate, and was killed in the following year.

In 864 a descendant of 'Alī, named Ḥasan b. Zayd, gained possession of Tabaristān and occupied the great city of Rayy near Teheran. A year later the province was reconquered by the Tāhirid governor of Khurasan, so that Ḥasan was obliged to retreat for refuge to the land of the Dailam. But he returned soon, and after many reverses ruled over Tabaristān and Jurjān for many years.

13. **Reign of Mu'tazz.**—Mu'tazz, proclaimed caliph at Baghdad in Jan. 866, devoted himself to the object of freeing himself from the omnipotent Turkish generals, especially Waṣif and Boghā, who had opposed his election. But such a task demanded an ability and energy which he did not possess. He was obliged to grant them amnesty and to recall them to Sāmarrā. But a more difficult problem was the payment of the Turkish, Persian and African guards, which was said to have amounted in A.H. 252 to 200,000,000 dirhems (about £6,500,000), or apparently twice the revenue derived from the land-tax. As the provincial revenues annually decreased, it became impossible to pay this sum. Upon a further demand, Mu'tazz, having failed to procure the money, was seized upon and tortured, and died of starvation in prison (July 868).

The dismemberment of the empire continued fast in these years, and the caliph was compelled to recognize the virtual independence of the governors Ya'qūb the Saffārid (*see* SAFFĀRIDS and PERSIA, HISTORY, § B) in Sistān, and Aḥmad b. Ṭulūn in Egypt.

14. **Reign of Muhtadī.**—Immediately after the seizure of Mu'tazz, the Turks proclaimed as caliph one of the sons of Wāthiq with the title of *al-Muhtadī billāh* ("the guided by God"), who, however, refused to occupy the throne until his predecessor had solemnly abdicated. Muhtadī, who was a man of noble and generous spirit and had no lack of energy, began by applying the precarious measure of power which was left him to the reform of the court. He devoted himself to the administration of justice, and gave public audiences to the people for the redress of their grievances, and endeavoured to break the supremacy of the Turks and other mercenaries. But Muhtadī came too late, and the Turks did not leave him time to finish his work. The soldiery he had gained over for himself were not strong enough. Muhtadī was overwhelmed and killed by the Turks (June 870).

15. **Reign of Mu'tamid.**—A son of Mutawakkil was brought out of prison to succeed his cousin, and reigned for 23 years under the name of *al-Mu'tamid 'ala'llāh* ("he whose support is God"). During his reign the Tāhirids were crushed in 873 by Ya'qūb the Saffārid, whose short-lived empire in 900 passed into the hands of the Sāmānids, who had been governors of Transoxiana from the time of Ma'mūn, and after the fall of the Tāhirids, had been confirmed in this office by the caliph. After 900 they were independent princes, and under their dominion these districts attained to high prosperity.

Mu'tamid had also to deal with a rising of the negro slaves in the province of Baṣra; it lasted from 869 to 883, and tasked the Government to its utmost. He died in Oct. 892. The seat of the Caliphate had already been restored to Baghdad.

16. **Reign of Mu'tadīd.**—Mu'tadīd may be called, after Maṣṣūr, the most able and energetic of all the Abbasid rulers. He took good care of the finances, reformed the administration,

was an excellent commander in war, and maintained order as far as possible.

Almost simultaneously with the rising of the negro slaves in Baṣra there arose in the province of Kūfa the celebrated sect of the Carmathians (*q.v.*), Fātimites or Ismā'īlites. The founder of a Carmathian state in Bahrein, the north-eastern province of Arabia (actually called Laḥsā) in the year 900 routed an army sent against him by Mu'taḍid.

Mu'taḍid died in March 902 leaving the Caliphate to his son.

17. **Reign of Muqtafi.**—Muqtafi inherited his father's intrepidity, and seems to have had high personal qualities, but his reign of six years was a constant struggle against the Carmathians. But, to avenge their defeat, they lay in wait for the great pilgrim caravan on its return from Mecca in 906 and massacred 20,000 pilgrims, making an immense booty. This horrible crime raised the whole Muslim world against them.

The war with the Byzantines was conducted with great energy during the reign of Muqtafi, and the dominion of the Tūlūnids in Egypt was overthrown.

18. **Reign of Muqtadir.**—The sudden death of Muqtafi in Aug. 908 was a fatal blow to the prestige of the Caliphate, for the new caliph, his brother, *al-Muqtadir billāh* ("the powerful through God") was only 13 years of age when he ascended the throne, and allowed himself to be governed by his mother and her ladies and eunuchs. The 24 years of Muqtadir's reign are a period of rapid decay. The most important event in the reign was the foundation of the Fātimite dynasty, which reigned first in the Maghrib and then in Egypt for nearly three centuries. (See FĀTIMITES and EGYPT: *History*, "Muḥammadan.")

Far more dangerous, however, for the Caliphate of Baghdad at the time were the Carmathians of Bahrein. In 923 they took and ransacked Baṣra; in the first month of the following year the great pilgrim caravan on its return from Mecca was overpowered; 2,500 men perished, while an even larger number were made prisoners and brought to Laḥsā, the residence of the Carmathian princes, together with an immense booty. Then Kūfa underwent the fate that had befallen Baṣra.

In 926 the caravan was allowed to pass on payment of a large sum of money. The Government of Baghdad resolved to crush the Carmathians, but a large army was utterly defeated in 927 and Baghdad was seriously threatened. Next year Mecca was taken and plundered; even the sacred Black Stone was transported to Laḥsā, where it remained till 950, when by the express order of the Imām, the Fātimite caliph, it was restored to the Ka'bah. Muqtadir fell in battle against a rebel commander in Oct. 932 at the age of 38 years. His reign, which lasted almost 25 years, was in all respects injurious to the empire.

19. **Reign of Qāhir.**—A brother of Muqtadir, named Qāhir, succeeded him; he was a drunkard, and derived the money for his excesses from promiscuous confiscation. In April 934 he was dethroned and blinded, and died in poverty seven years later.

During the last years of Muqtadir and the reign of Qāhir a new dynasty rose in the north of Persia, the Būyids. (See PERSIA: *History*.)

20. **Reign of Rāḍī.**—Muqtadir's son, who was then proclaimed caliph under the name of *ar-Rāḍī billāh* ("the content through God"), was pious and well-meaning, but inherited only the shadow of power. He created the office of Amīr al-Umarā, which nearly corresponds to that of Mayor of the Palace among the Franks. The empire was by this time practically reduced to the province of Baghdad; Khurasan and Transoxiana were in the hands of the Sāmānids, Fārs in those of the Būyids; Kirman and Media were under independent sovereigns; the Hāmdānids possessed Mesopotamia; the Sājids Armenia and Azerbaijan; the Ikshidites Egypt; as we have seen, the Fātimites Africa, the Carmathians Arabia.

21. **Reign of Muttaqī.**—Rāḍī died in Dec. 940. Another son of Muqtadir was then proclaimed caliph under the name of *al-Muttaqī billāh* ("he who guards himself by God"). At the time of his accession the Amīr al-Umarā was the Turkish general, Bajkam. Unfortunately Bajkam died soon after, and his death was followed by general anarchy. A certain Barīdī, who had

carved out for himself a principality in the province of Baṣra, laid siege to Baghdad, and Muttaqī fled to the Hāmdānīd, prince of Mosul, who then marched against Baghdad, and succeeded in repelling Barīdī. In return he obtained the office of Amīr al-Umarā. But the Dailamite and Turkish soldiery did not suffer him to keep this office longer than several months. Tūzūn, a former captain of Bajkam, compelled him to return to Mosul and took his place. Muttaqī fled again to Mosul and thence to Rakka. Tūzūn found means to entice him to his tent, and had his eyes put out (Oct. 944).

22. **Reign of Mustakfi.**—As successor Tūzūn chose *al-Mustakfi billāh* ("he who finds full sufficiency with God"), a son of Muktafi. This prince, still more than his predecessors, was a mere puppet. One of the Būyid princes marched about this time against Baghdad, which he entered in Dec. 945 and was acknowledged by the caliph as legal sovereign, under the title of sultan. He assumed at this time the name of Mu'izz addaula. Mustakfi was soon weary of this new master, and plotted against him. At least Mu'izz addaula suspected him and deprived him of his eyesight (Jan. 946). There were thus in Baghdad three caliphs who had been dethroned as well as blinded, namely, Qāhir, Muttaqī and Mustakfi.

23. **Reign of Muṭī'.**—Mu'izz addaula's choice fell on a son of Muqtadir, who took the title of *al-Muṭī' billāh* ("he who obeys God"). The sultan, reserving to himself all the powers and revenues of the Caliphate, allowed the caliph merely a secretary and a pension of 5,000 dirhems a day. Muṭī' was compelled to abdicate in Aug. 974.

24. **Reign of Ṭā'ī.**—Muṭī' left the empty title of caliph to his son *al-Ṭā'ī 'l-lā-amrī' llāh* ("the obedient to the command of God"). Under 'Aḍud addaula the power of the Būyids reached its zenith. His empire stretched from the Caspian to the Persian sea, and in the west to the eastern frontier of Syria. But after his death in the year 983 his sons fought one against the other. In 990 the youngest of them, Bahā addaula, had the upper hand, and wishing to deprive the caliph Ṭā'ī of his possessions, compelled him to abdicate (A.D. 991).

25. **Reign of Qāḍir.**—A grandson of Muqtadir was then made caliph under the name of *al-Qāḍir billāh* ("the powerful through God"). During this Caliphate the Būyid princes were in continual war with one another. Meanwhile events were preparing the fall of their dynasty. In 961 a Turkish general of the Sāmānids had founded for himself a principality in Ghazni, and one of his successors, Maḥmūd, conquered the whole of Khurasan and Sijistān, with a great part of India. He then attacked the Būyids, and would have destroyed their dynasty but for his death in the year 1030. Qāḍir died in Nov. 1031.

26. **Reign of Qā'im.**—He was succeeded by his son, who at his accession took the title of *al-Qā'im bi-amrī' llāh* ("he who maintains the cause of God"). During the first half of his long reign took place the development of the power of the Seljuk Turks. In 1038 Tughril Beg, their chief, beat the army of the Ghaznavids and made his entry into Nishapur. Thenceforth his progress was rapid. (See SELJUKS.) The situation in Baghdad had become so desperate that the caliph called Tughril to his aid. This prince entered Baghdad in Dec. 1055, and overthrew finally the dynasty of the Būyids. In 1058 he received from the caliph the title of "King of the East and West"; he was succeeded by his nephew, Alp Arslān, who died in 1072. Qā'im died two years later, April 1075.

27. **Reign of Muqtadī.**—In the first year of the Caliphate of *al-Muqtadī bi-amrī' llāh* ("he who follows the orders of God"), a grandson of Qā'im, the power of the Seljuk empire reached its zenith. All the eastern provinces, a great part of Asia Minor Syria with the exception of a few towns on the shore, the main part of West Africa acknowledged the caliph of Baghdad as the Imām. Yemen had been subjected, and at Mecca and Medina his name was substituted in the public prayers for that of the Fātimite caliph. But after the death of Malik Shah a contest for the sultanate took place; the day after his son, Barkiyāroq entered Baghdad in triumph (Feb. 1094) the caliph died suddenly, apparently by poison.

28. **Reign of Mustazhir.**—*Al-Mustazhir billāh* ("he who seeks to triumph through God"), son of Muqtadī, was only 16 years old when he was proclaimed caliph. His reign is memorable chiefly for the growing power of the Assassins (*q.v.*) and for the first crusade. (See CRUSADES.) After the death of Barkiyāroq in Nov. 1104, his brother, Muhammad, reigned till April 1118. His death was followed about four months later by that of Mustazhir.

29. **Reign of Mustarshid.**—*Al-Mustarshid billāh* ("he who asks guidance from God"), who succeeded his father in Aug. 1118, distinguished himself by a vain attempt to re-establish the power of the caliph. In 1135 he was assassinated.

30. **Reign of Rāshid.**—*Al-Rāshid billāh* ("the just through God") tried to follow the steps of his father. But the Seljuk sultan, Mas'ūd took Baghdad and had Rāshid deposed (Aug. 1136). Rāshid escaped, but was murdered two years later.

31. **Reign of Muqtafi.**—His successor *Al-Muqtafi bi-amri'llāh* ("he who follows the orders of God"), son of Mustazhir, had better success. He was real ruler not only of the district of Baghdad, but also of the rest of 'Irāq, which he subdued by force. He died in March 1160. Under his reign the central power of the Seljuks was rapidly sinking. In the west, Zengī, the prince of Mosul, had extended his dominion over Mesopotamia and the north of Syria, where he had been the greatest defender of Islam against the Franks. At his death in 1146, his noble son, Nūraddin, continued his father's glorious career.

32. **Reign of Mustanjid.**—*Al-Mustanjid billāh* ("he who invokes help from God"), the son of Muqtafi, enlarged the dominion of the Caliphate by making an end to the State of the Mazyadites in Hillah. The greatest event towards the end of his Caliphate was the conquest of Egypt by the army of Nūraddin, the overthrow of the Fātimite dynasty, and the rise of Saladin. He was killed by his major-domo in Dec. 1170.

33. **Reign of Mustadī.**—His son and successor *al-Mustadī bi-amri'llāh* ("he who seeks enlightenment by the orders of God"), though in Egypt his name was now substituted in public prayers for that of the Fātimite caliph, was unable to obtain any real authority. By the death of Nūraddin in 1174 Saladin's power became firmly rooted. Mustadī died in the month of March 1180.

34. **Reign of Nāṣir.**—Quite a different man from his father was his successor *al-Nāṣir bi-dīni'llāh* ("he who helps the religion of God"). During his reign Jerusalem was reconquered by Saladin on Oct. 2, 1187. Nāṣir was very ambitious; he had added Khūzistān to his dominions, and desired to become also master of Media. Here, however, he came into conflict with the then mighty prince of Khwārizm (Khīva), and invoked the help of the Mongols against him. When Nāṣir died (Oct. 1225), the eastern provinces of the empire had been trampled down by the Mongol hordes under Jenghiz Khān, the towns burned, and the inhabitants killed without mercy.

35. **Reign of Zāhir.**—*Al-Zāhir bi-amri'llāh* ("the victorious through the orders of God") died within a year after his father's death, in July 1226.

36. **Reign of Mustanṣir.**—*Al-Mustanṣir billāh* ("he who asks help from God") was caliph till his death in Dec. 1242. In 1227 Jenghiz Khān died, but the Mongol invasion continued to advance with immense strides.

37. **Reign of Musta'sim.**—*Al-Musta'sim billāh* ("he who clings to God for protection"), the last caliph of Baghdad, was a narrow-minded, irresolute man, guided, moreover, by bad counsellors. In Jan. 1256 Hülāgū, the brother of the great khān of the Mongols, crossed the Oxus, and began by destroying all the strongholds of the Ismā'īlis. In Jan. 1258 Hülāgū arrived under the walls of Baghdad. Musta'sim was obliged to surrender and came with his retinue into the Mongol camp. The city was then given up to plunder and slaughter; the caliph, after having been compelled to bring forth all the hidden treasures of the family, was killed with two of his sons and many relations. With him expired the eastern Caliphate of the Abbasids, which had lasted 524 years, from the entry of Abu'l-'Abbās into Kūfa.

In vain, three years later, did Abu'l-Qāsim Aḥmad, a scion of the race of the Abbasids, who had taken refuge in Egypt with Baybars the Mameluke sultan, and who had been proclaimed

caliph under the title *al-Mustanṣir billāh* ("he who seeks help from God"), make an effort to restore a dynasty which was now for ever extinct. At the head of an army he marched against Baghdad, but was defeated and killed before he reached that city. Then another descendant of the Abbasids, who also had found an asylum in Egypt, was proclaimed caliph at Cairo under the name of *al-Hākim bi-amri'llāh* ("he who decides according to the orders of God"). His sons inherited his title, but, like their father, remained in Egypt without power or influence. (See EGYPT: History, "Muhammadan period.") This shadow of sovereignty continued to exist till the conquest of Egypt by the Turkish sultan, Selim I., who deposed the last of them, Mutawakkil. (See TURKEY: History.) He died at Cairo, a pensionary of the Ottoman Government, in 1538.

There has been much diversity of opinion in the Muslim world on the subject of the Caliphate since the 1st century of the Muhammadan era, but only one theory—that of Sunni orthodoxy—has obtained more than temporary or local realization. (See ISLAMIC INSTITUTIONS.) This theory of the Sunni Caliphate grew out of the actual political facts connected with the establishment of the vast Arab empire stretching from the shores of the Atlantic to Transoxiana; it assumed that all believers would always live under one Muslim ruler, who would be of the tribe of Quraysh (to which the Prophet himself had belonged), and for nearly nine centuries the caliph was actually a Qurayshite. But the empire remained undivided for little more than a century, and broke up into a number of independent states; so that by the 10th century the authority of the caliph in Baghdad hardly extended beyond the walls of that city, and he himself was a puppet in the hands of his Turkish mercenaries. The theory, however, survived its failure to realize itself and even independent monarchs recognized the caliph as the source of all authority, and would apply to him for a diploma of investiture or a title of honour, in order that their position might be legitimized and the tender consciences of their subjects satisfied. After the last Abbasid caliph in Baghdad was put to death by the Mongols in 1258, a shadowy continuation of the dynasty was set up in Cairo under the protection of the Mameluke sultans and, though the caliph was now powerless to exercise any influence on political affairs, he was still regarded in popular sentiment as the only legitimate source of authority, and requests still came for titles and diplomas from independent princes. On the other hand, particularly after the Mongol conquests, a new theory of sovereignty was devised by the Muslim legists, who began to represent the authority of the ruler as derived directly from God Himself, "Who giveth the kingdom to whomsoever He wills, and raiseth whomsoever He wills to honour." No authorization, therefore, from the caliph was any longer held to be necessary, and the legists impressed the duty of obedience to any ruler who had established his position by force of arms.

**Development from 13th Century.**—Accordingly from the latter part of the 13th century onwards, independent sultans—Maghrebins, Indians, Seljuks and even Turkomans and Shaybanids—began to assume to themselves the title of caliph in addition to other high-sounding titles, and this title, which in earlier ages had been considered to be the exclusive prerogative of one supreme sovereign, now came to be applied to any number of princes, some of whom were persons of quite insignificant status. The rising power of the Ottoman sultans naturally fell in with the prevailing fashion, and we accordingly find that the title Khalifah was applied as early as 1362 to Murād I., and afterwards to each one of his descendants on the Ottoman throne. There is, therefore, no justification for the legend that the first of the Ottoman sultans to assume this title was Selim I., and still less historical evidence is there for the story that after his occupation of Cairo in 1517 the dignity of the caliph was transferred to him by the last of the Abbasid caliphs, Mutawakkil. This legend was first put forward in 1787 by D'Osson and passed unchallenged from one European history to another, and was adopted by Turkish writers also, and in modern times it became a commonplace in the propagandist literature of the Muhammadan world in support of the Ottoman claim to the

Caliphate. As the Ottoman conquests extended the boundaries of their enormous empire, it became clear that the Turkish sultan was the only Muhammadan monarch possessing territories, power and wealth commensurate with the dignity of so exalted a title, and the same halo of glory gathered round Constantinople as in former centuries had been associated with the cities of Damascus and Baghdad.

**The Ottoman Diplomacy.**—The Ottoman sultans do not appear to have attached much importance to the title of Khalifah until in the 18th and 19th centuries Turkish diplomatists found it convenient in their relations with Christian Powers to make use of the false analogy current in Europe between the caliph and the pope, and to claim for the sultan spiritual authority over Muslims who were not actually his subjects. Abdul Hamid II. (1876–1908) especially emphasized this claim, and from the outset of his reign endeavoured to obtain recognition of himself as caliph by sending emissaries to Egypt, Tunis, India, Afghanistan, Java and China. His deposition in 1908 did not entail the abandonment of this policy, and in the treaties made between the new constitutional Government in Turkey and the States which between 1908 and 1913 annexed territories formerly provinces of the Turkish empire, e.g., Bosnia, Hercegovina, Libya, Bulgaria and Macedonia, it was stipulated (in regard to the first three) that the name of the sultan should continue to be mentioned in the public prayers as caliph, and that in all of them the appointment of Muslim ecclesiastics should be authorized by the Shaykh al Islam in Constantinople.

When Turkey entered into the World War in 1914 a further attempt was made to make political use of the Turkish claim to the Caliphate by the proclamation of a Jihād in which all Muslims were called upon to fight in defence of the Khalifah and were threatened with the punishment of hell if they supported his enemies. The lack of response to this appeal revealed the unreality of this assumption of authority, but many Muslims, especially in India, were undoubtedly distressed at the fact of hostilities between Turkey and the Governments under which they themselves lived, and after the Armistice in 1918 much sympathy was aroused for the Caliphate, and fears were expressed lest the terms of peace should cripple the power of Turkey.

**Abolition of Sultanate and Caliphate.**—In Nov. 1922 the National Assembly declared a republic and abolished the Sultanate; Muhammad VI. was deposed and his cousin, Abdul Majid, elected Khalifah of all the Muslims, but the exact nature of his functions had not been clearly defined before he was sent into exile in March 1924 and the Ottoman Caliphate abolished altogether. A few days later King Husayn of the Hijaz was proclaimed caliph in Mecca and Transjordan, and received some recognition also in Palestine and Syria; but in the following October he abdicated, just before the victorious Wahhabis entered Mecca. All three of these claimants have since died, and the recognition paid to any holders of this title is merely local, e.g., the sherif of Morocco is regarded as caliph by his own subjects, and four petty chiefs in the Malay archipelago enjoy the title.

**Future of the Caliphate.**—Meanwhile the problem that faces the Muslim world is being much discussed. The orthodox Sunni legists maintain that the Muslim world must always have a Khalifah as head of the community, and those in sympathy with this view held an international Caliphate Congress in Cairo in May 1926; but no practical conclusion was arrived at. The number of those Muslim theologians who brave orthodox opinion by declaring that there is no longer any need for such an institution, is small; but, outside theological circles, there is a growing readiness to accept the altered circumstances of the case.

**BIBLIOGRAPHY.**—A full bibliography is given in vol. ii. (chap. x., xi. and xii.) and vol. iv. (chap. x.) of the *Cambridge Medieval History* (1913, 1923). The outstanding works on this period are L. Caetani, *Annali dell' Islām* (up to the death of 'Alī, A.D. 661) (1905–26); H. Lammens, *Études sur le regne du calife Omayyade Mo'awia Ier* (1906–07); J. Wellhausen, *Das arabische Reich und sein Sturz* (1902; trans. M. G. Weir, 1927); A. Mez, *Die Renaissance des Islāms* (1922); T. W. Arnold, *The Caliphate* (1924); *Oriente Moderno* (1921–28); A. J. Toynbee, *Survey of International Affairs* (1925), vol. i. *The Islamic World* (1927). (T.W.A.)

**CALIVER**, a firearm used in the 16th century. The word is an English corruption of "calibre," and arises from the "arquebus of calibre," that is, of standard bore, which replaced the older arquebus. "Caliver," therefore, is practically synonymous with "arquebus." The heavier musket, fired from a rest, replaced the caliver or arquebus towards the close of the century.

**CALIXTUS or CALLISTUS**, the name of three popes.

**CALIXTUS I.**, pope from 217 to 222, was little known before the discovery of the book of the *Philosophumena*. From this work which is in part a pamphlet directed against him, we learn that Calixtus was originally a slave and engaged in banking. Falling on evil times, he was brought into collision with the Jews, who denounced him as a Christian and procured his exile to Sardinia. On his return from exile he was pensioned by Pope Victor, and, later, was associated with Pope Zephyrinus in the government of the Roman Church. On the death of Zephyrinus (217) he was elected in his place and occupied the papal chair for five years. His theological adversary Hippolytus, the author of the *Philosophumena*, accused him of having favoured the modalist or Patripassian doctrines and of certain relaxations of discipline. Calixtus died in 222. In the time of Constantine the Roman Church reckoned him officially among the martyr popes.

(L. D.)

**CALIXTUS II.** (d. 1124), pope from 1119 to 1124, was Guido, a member of a noble Burgundian family, who became archbishop of Vienne about 1088, and belonged to the party which favoured reform in the Church. In Feb. 1119 he was chosen pope at Cluny, succeeding Gelasius II., and in opposition to the anti-pope Gregory VIII., who was in Rome. Soon after his consecration he opened negotiations with the emperor Henry V., to dispose of the dispute over investiture. Terms of peace were arranged, but at the last moment difficulties arose and the treaty was abandoned; and in Oct. 1119 both emperor and anti-pope were excommunicated at a synod held at Reims. The journey of Calixtus to Rome early in 1120 was a triumphal march. He was received with great enthusiasm in the city, while Gregory having fled to Sutri, was delivered into his hands and treated with great ignominy. Through the efforts of some German princes negotiations between pope and emperor were renewed, and the important Concordat of Worms made in Sept. 1122 was the result. He died in Rome on Dec. 13 or 14, 1124.

See M. Maurer, *Papst Calixt II.* (Munich, 1889); U. Robert, *Histoire du pape Calixte II.* (Paris, 1891); and A. Hauck's *Realencyklopädie*, Band iii. (Leipzig, 1897).

**CALIXTUS III.** (c. 1378–1458), pope from 1455 to 1458, was a Spaniard named Alphonso de Borgia, or Borja. A native of Xativa, he gained a great reputation as a jurist, becoming professor at Lerida; in 1429 he was made bishop of Valencia, and in 1444 a cardinal, owing his promotion mainly to his close friendship with Alphonso V., king of Aragon and Sicily. Chosen pope in April 1455, he endeavoured fruitlessly to organize a crusade. Calixtus became involved in a quarrel with his former friend, Alphonso of Aragon, now also king of Naples, and after the king's death in June 1458 he refused to recognize his illegitimate son, Ferdinand, as king of Naples, asserting that this kingdom was a fief of the Holy See. Notorious for nepotism, he was responsible for introducing his nephew, Rodrigo Borgia, afterwards Pope Alexander VI., to Rome. He died on Aug. 6, 1458.

See A. Hauck's *Realencyklopädie*, Band iii. (Leipzig, 1897).

**CALIXTUS, GEORG** (1586–1656), Lutheran divine, was born at Medelbye, Schleswig, on Dec. 14, 1586. After studying philology, philosophy and theology at Helmstedt, Jena, Giessen, Tübingen and Heidelberg, he travelled through Holland, France and England, where he became acquainted with the leading reformers. On his return in 1614 he was appointed professor of theology at Helmstedt by the duke of Brunswick, who had admired the ability he displayed when a young man in a dispute with the Jesuit Augustine Turrianus. Calixtus held this post for 40 years, and made Helmstedt a centre of reasonableness in an age of bitter theological controversy. He constantly pressed for a milder treatment of confessional differences, and thought that a basis for the reunion of all the churches could be found in the

study of the Christian fathers. His ideas were those later advocated (also fruitlessly) by Leibnitz. In 1613 he published a book, *Disputationes de praecipuis religionis christianae capitibus*, which provoked the hostile criticism of orthodox scholars; in 1619 he published his *Epitome theologiae*, and some years later his *Theologia Moralis* (1634) and *De Arte Nova Nihusii*. Statius Buscher charged the author with a secret leaning to Romanism. Calixtus refuted the accusation of Buscher, but after the conference of Thorn (1645), a new charge was preferred against him, principally at the instance of Abraham Calovius (1612–1686), of a secret attachment to Calvinism. The disputes on the possibilities of the reconciliation desired by Calixtus known in the Church as the Syncretistic controversy, lasted during the whole lifetime of Calixtus, and distracted the Lutheran Church, till a new controversy arose with P. J. Spener and the Pietists of Halle. Calixtus died on March 16, 1656.

See E. L. T. Henke, *Georg Calixtus und seine Zeit* (1853–60); also Isaak Dorner, *Gesch. d. protest. Theol.* pp. 606–624; and especially Herzog-Hauck, *Realencyklopädie*.

**CALL.** A term used on the English and American stock exchanges for a contract by which, in consideration of a certain sum, an "option" is given by the person making or signing the agreement to another named therein or his order or to bearer, to "call" for a specified amount of stock at a certain day for a certain price. A "put," which is the reverse of a "call," is the option of selling (putting) stock at a certain day for a certain price. A combined option of either calling or putting is termed a "straddle," and sometimes on the American stock exchange a "spread-eagle."

The word is also used in connection with joint-stock companies, to signify a demand for instalments due on shares, when the capital of the company has not been demanded or "called" up at once. (See COMPANY: Options.)

**CALLA**, in botany, a genus of the arum family (Araceae), comprising only one species (*C. palustris*), known as arum lily, water arum or wild calla, found widely in bogs in cool north temperate and subarctic regions. It is a handsome plant, with heart-shaped leaves, showy white flowering spathes and a fruit cluster of brilliant red berries. The well-known calla or calla lily of the gardeners is a species of *Zantedeschia* (q.v.). (See ARACEAE.)

**CALLABLE**, a term relating to securities, meaning that the issuer retains the right to call in, repay, or redeem them under specified conditions. Callable or redeemable stock is that upon which the issuing company has retained the option, under the conditions and upon the terms specified in its certificate of incorporation, of redeeming it or buying it back from the stockholders. Callable or redeemable bonds are those which by the terms of their issue may be called for redemption by the issuing company before the date of their maturity.

**CALLAGHAN, SIR GEORGE ASTLEY** (1852–1920), British admiral, was born in London on Dec. 21, 1852, the son of an army captain, and entered the navy in 1866. He was promoted captain while on service on the China station in 1894, and was then (1894–97) naval adviser to the inspector of fortifications at the War Office. He was in command of the "Endymion" on the China station at the time of the Boxer rising in 1900, and commanded the naval brigade which entered Peking. He held various other important commands in the years 1900–14 and for the three years immediately before the World War was commander-in-chief of the home fleets, which he brought to a high state of efficiency and readiness. Callaghan was commander-in-chief at the Nore (Jan. 1915–March 1918), and was promoted admiral of the fleet in 1917. He died in London on Nov. 23, 1920.

**CALLANDER**, police burgh and parish, Perthshire, Scotland, 16 m. north-west of Stirling by the L.M.S.R. Pop. (1931), 1,572. Situated on the north bank of the Teith, here crossed by a three-arched bridge, and sheltered by a ridge of wooded hills, it is in repute as a health resort, and there is a large hydro on the south side of the river. A mile and a half north-east are the Falls of Bracklinn (Gael. "white-foaming pool"), while two miles north-west is the Pass of Leny. Callander owes much of its prosperity to the fact that it is the centre from which the Trossachs is usually visited, the route being that described in Scott's *Lady of*

*the Lake*. The ascent of Ben Ledi is commonly made from the town.

**CALLANDER-PEMBROKE ROAD**, a highway beginning at Pembroke on the Ottawa river and ending at Lake Nipissing in the province of Ontario, Canada. It forms part of the Trans-Canada highway and is about 140 m. in length, improved throughout. It passes through Algonquin Provincial park, which

is notable as a hunting and fishing region, while the Chalk river, Mackey and Mattawa also lie in its path.

CALLANDER-PEMBROKE ROAD

**CALLAO**, a city, chief port and constitutional province of Peru. Pop. (1927), 53,258, about 50,000 of whom were in the city. The province (area 14½ sq.m.), a low peninsula south of the Rimac river, includes the city and its suburbs, Bellavista to the east, with a large Anglo-American colony, La Punta, at the western extremity of the peninsula, a bathing resort with casino, pier, hotels, private houses and naval academy, and Chucuito, between La Punta and Callao; also the islands of San Lorenzo, Frontón, Los Palominos and other islets. San Lorenzo (1 by 4½ m. in extent, 1,050 ft. high) has an arsenal and submarine base, Los Palominos, a revolving light with a visibility of 18 miles. Though politically and administratively a province, Callao has the standing of a department. The climate is temperate and equable, although the sky is overcast for half the year. Agricultural products include sugar, maize, fruits and vegetables for local markets. The city (12° 4' S., 77° 13' W.) is the port of Lima, 8½ m. distant, with which it is connected by train, electric tramway and automobile. This section of the Central railway was opened in 1851, the first in South America. The Avenida del Progreso, built in 1924, is a modern, reinforced concrete highway.

The harbour of Callao, a bay sheltered by a tongue of land on the south (La Punta) and by San Lorenzo, is one of the best anchorages on the Pacific coast of South America. The city is south of the bay, 8 ft. above sea-level. The houses are mostly adobe, of poor design, the streets narrow and ill-paved. Recent public improvements, however—widening and paving the streets, beautifying the plazas, restoring the castle of Real Felipe (1770–75), building reservoirs to double the water-supply and new systems of sewage disposal, as well as many imposing new edifices—are fast changing the appearance of Callao. A slaughter-house and refrigerating plant, the first of its kind in Peru, was finished in 1927. It supplies meat to Lima and vicinity and handles dairy products and fruit for the local trade. Among the principal buildings are the customs-house, prefecture, post-office, court-house, barracks, churches, hospitals, markets, clubs and large commercial houses. There are five plazas with statues of national heroes. Business activities are largely connected with shipping and forwarding merchandise. As Callao handles most of the imports of the country, there are many wholesale firms, banks, steamship offices and consulates. Manufactories include flour-mills, breweries and bottling works, foundries, machine-shops and others of less importance. There are 11 primary schools with 104 teachers and 5,536 pupils (1926), also secondary and commercial schools and a recently established school of fisheries. Callao is a port of call for many foreign steamship lines. The Peruvian line, Compañía Peruana de Vapores y Digue del Callao, runs between Peruvian ports and Panama. In 1926, 1,402 vessels with a tonnage of 2,628,696, entered the port of Callao.

Chief exports are sugar, cotton, wool, hides, silver, copper, vanadium lead and other minerals; chief imports, machinery, vehicles, implements, food-stuffs, cotton and other textiles, building materials, paint, jute, paper and general merchandise for personal, household and industrial uses. As improvement of harbour and docks is centrally important, a contract closed with a North American firm in 1928, provides for the construction of new docking facilities in addition to those already in use. Two granite breakwaters, with an entrance 500 ft. wide, will enclose an area of 667 acres. The main channel will be

37 ft. deep, with a depth of 32 ft. over the rest of the dredged area. Four piers, 600 ft. long, will be built, two of which will have fireproof sheds with water service, tracks for freight cars, cement ways for trucks and crane equipment. At a cost of \$6,300,000, this new terminal will be finished in 1932 and will be called Terminal Leguia. Callao handles at present an average of 125,000 tons a year exports, and 400,000 tons imports. The new facilities will have a capacity of 1,000,000 tons. The port area is large enough to include other docks as needed.

Callao has had an eventful history. Founded in 1537, two years after Lima, it was repeatedly sacked by Drake (1578) and other buccaneers. The centre of trade with Spain, it had become the richest port on the Pacific when it was destroyed by a tidal wave and earthquake in 1746 in which 6,000 persons perished. It was rebuilt and strongly fortified. Several times besieged by Spanish fleets, it was finally abandoned by Spain in 1826. A Spanish squadron which attacked it on May 2, 1866, was defeated, and Spanish claims in Peru came to an end. (M. T. Br.)

**CALLCOTT, SIR AUGUSTUS WALL** (1779-1844), English landscape painter, was born at Kensington in 1779 and died there in 1844. His first study was music; but by the age of 20 he had determined to give up music, and had exhibited his first painting at the Royal Academy. He became R.A. in 1810, was knighted in 1827, and in 1834 was appointed surveyor of the royal pictures.

His wife, MARIA, Lady Callcott (1786-1844), whom he married in 1827, was a daughter of Admiral Dundas and widow of Captain Thomas Graham, R.N. (d. 1822). She published accounts of her visits to India (1812) and to the environs of Rome (1820); *Memoirs of Poussin* (1820); a *History of France*; a *History of Spain* (1828); *Essays toward a History of Painting* (1836); *Little Arthur's History of England* (1836); and the *Scripture Herbal* (1842); etc.

**CALLCOTT, JOHN WALL** (1766-1821), English musician, brother of Sir Augustus Callcott, R.A., was born in Kensington Nov. 20, 1766, his father having been a bricklayer and builder. His reputation as a composer rests chiefly upon his concerted vocal works, such as the catch "O beauteous fair," the canon "Blessed is he" and the glee "Dull repining sons of care."

Callcott's son, WILLIAM HUTCHINS CALLCOTT (1807-1882), inherited to a large extent the musical gifts of his father. His song, "The last man," and his anthem, "Give peace in our time, O Lord," were his best-known compositions.

**CALENDAR, HUGH LONGBOURNE** (1863-1930), British physicist, was born at Hatherop in Gloucestershire. He was educated at Marlborough and at Cambridge; he held the post of professor of physics at McGill college, Montreal (1893-98); at University college, London (1898-1902) and at the Imperial College of Science.

His work in physics is mainly on heat and thermodynamics; he has been successful in devising and carrying out accurate methods of measurement and in designing new apparatus. The electrical resistance thermometer, with the Callendar-Griffiths bridge and various recording devices used with it, was the subject of papers published in 1886-87. This was followed by his work on the electrical continuous flow calorimeter, giving a new method of measuring specific heats of liquids, which eliminates the water equivalent of the apparatus and simplifies the radiation correction; the full description was given in 1902. In addition, Callendar is responsible for a compensated air thermometer (1891) and a radio-balance (1910).

His researches on steam led to the formulation of the Callendar steam equation and the publication of *Callendar Steam Tables* (1915); *Properties of Steam and Thermodynamic Theory* (1921); *Abridged Callendar Steam Tables C. and F. Units* (1922 and 1927), and *Callendar Steam Diagram C. and F. Units* (1922). The work on steam at high pressures and temperatures is still carried forward at the direct request of steam turbine manufacturers and the Electrical Research Association. In 1925 he presented a report to the latter association on the continuous flow method of measuring the total heat of steam at high pressures. Callendar is the author of a number of papers on various subjects

such as internal combustion engines, thermometric scales, radiation, vapour pressure, osmotic pressure of solutions, absolute expansion of mercury and the boiling point of sulphur. He is also responsible for Air Ministry reports and memoranda on work carried out by himself and colleagues on *Dopes and Detonation* (1926) and on the effect of anti-knock compounds on engine-knock (1927). He died in London on Jan. 21, 1930.

Callendar was a member and officer of many learned societies; he was awarded the Rumford Medal of the Royal Society in 1906 and the first Duddell Memorial Medal of the Physical Society in 1924; he received the C.B.E. in 1920.

**CALLES, PLUTARCO ELÍAS** (1877- ), Mexican statesman and military leader, president of Mexico in 1924-28, born at Guaymas, Sonora, Sept. 25, 1877. Little is known of his early life, however, it is certain that almost to manhood he lived the life of the poorer class. He attended the school of his native town, where at the age of 17 years he became a teacher in the primary school. Later he became superintendent of schools in Hermosillo, and it was there that he began to show the qualities which have made him an outstanding figure in Mexico. His interest in social and economic reforms caused him to join the revolutionary movement which overthrew Porfirio Díaz. In 1913 he joined the forces of Gen. Carranza in the struggle against the Huerta administration, attaining the rank of general. In the border wars of 1915 he served with Gen. Obregón in the campaigns against Villa, and in 1917 became governor of Sonora. During his brief administration as governor he succeeded in establishing an industrial school at Hermosillo and in securing legislation favourable to labour and prohibition. He was minister of commerce, labour and industry under Carranza, secretary of war under the provisional Government of Adolfo de la Huerta and secretary of the interior under President Obregón. In 1924, as the candidate of the Labour Party, he was elected president for the four-year term ending Dec. 1, 1928. President Calles came into power pledged to continue the work begun under President Obregón: land for the peasants, work for the workers, education for the masses and legitimate profits for decent capital and honest business. The chief international problems of the administration grew out of the alien land and petroleum laws passed by the Mexican Congress, at the president's request, in Dec. 1925 (see MEXICO: History). Early in Jan. 1926, just as a spirited diplomatic controversy with the United States concerning these laws reached an apparent crisis, the Mexican Roman Catholic episcopate took a positive stand against the religious and educational provisions of the Constitution and thus precipitated a conflict between church and State. A decision of the Mexican Supreme Court (Nov. 1927) declaring certain articles of the petroleum law unconstitutional and the diplomacy of Dwight Morrow, U.S. ambassador to Mexico, have brought about amicable relations between the two nations. The solution to the church question has proved more difficult. He was succeeded by Portes Gil.

**CALLIAS**, tyrant of Chalcis in Euboea, wished, with the assistance of Philip of Macedon, to subdue the whole island. But, finding Philip unwilling to help him, he applied to the Athenians, though he had previously fought against them. They were persuaded by Demosthenes to make an alliance with Callias, with whose help they drove out the pro-Macedonian tyrants from Eretria and Oreus, and at Demosthenes' suggestion handed over the tribute formerly paid by the Euboic cities to Athens to a Euboic synod sitting at Chalcis (Demosthenes, *De Pace*, 58; *Ep. Philippi*, 59; Diod. Sic. XVI. 74). At the end of his life he seems to have lived at Athens, and Demosthenes proposed to grant him the citizenship (Aeschines, *Contra Ctesiph.*, 85, 87).

**CALLIAS and HIPPONICUS**, two names borne alternately by the heads of a wealthy Athenian family. During the 5th and 4th centuries B.C. the office of *daduchus* or torch-bearer at the Eleusinian mysteries was the hereditary privilege of the family. The following members deserve mention.

1. **CALLIAS**, the second of the name, fought at the battle of Marathon (490). After the accession of Artaxerxes he was sent on an embassy to the Persian court (Herod. vii. 151). This

visit has been connected with the Peace referred to by the orators and Diodorus as the "Peace of Callias," but the contradictory nature of their statements about its date and terms, and the silence of Thucydides, make it doubtful whether any formal peace was concluded. (See CIMON.) At all events Callias's mission does not seem to have been successful; he was indicted for high treason on his return and sentenced to a fine of fifty talents.

See Grote, who refers to the ancient authorities, and accepts the treaty as a historical fact, *History of Greece*, ch. xlv., Curtius, bk. iii. ch. ii., denies the conclusion of any formal treaty; see also Ed. Meyer, *Forschungen*, ii.; J. B. Bury in *Hermathena*, xxiv. (1898); E. M. Walker, note 3, "The Peace of Callias," in *Camb. Anc. Hist.* vol. v.

2. HIPPOCRATES, son of the above. Together with Eurymedon he commanded the Athenian forces in the incursion into Boeotian territory (426 B.C.) and was slain at the battle of Delium (424).

See Thucydides iii. 91; Diod. Sic. xii. 65; Andocides, *Contra Alcibiadem*, 13.

3. CALLIAS, son of the above, was notorious for his profligacy and extravagance, and was ridiculed by the comic poets (Aristophanes, *Frogs*, 429, *Birds*, 283, and schol. Andocides, *De Mysteriis*, 110-131). His house is the scene of Xenophon's *Symposium* and Plato's *Protagoras* (*Var. Hist.* iv. 23). In 392 he was in command of the Athenian hoplites at Corinth, when the Spartans were defeated by Iphicrates. In 371 he was at the head of the embassy which made the "Peace of Callias."

See Xenophon, *Hellenica*, iv. 5, vi. 3; and DELIAN LEAGUE.

**CALLICRATIDAS**, Spartan admiral, succeeded Lysander as admiral of the Lacedaemonian fleet in 406 B.C. He found at once that his predecessor had made his position as difficult as possible, by setting his subordinates against him and returning to Cyrus all the supplies that he held. He won over the captains by calling them together, explaining that he had been appointed their commander, and asking "Now shall I stay, or go back and report that you do not wish me to command?" but he found the necessity of coming to Cyrus for money irksome, and declared that when he got home he would do his best to reconcile Sparta with Athens. He eventually got some money from Miletus, and fitted out a new fleet of 140 sail. He captured Methymna in spite of Conon's attempt to save it, and refused to sell into slavery the prisoners he took. He then chased Conon to Mitylene, and after a successful engagement in the harbour blockaded him there. Athens sent out a fleet of 150 sail to relieve Conon, and Callicratidas left 50 ships to hold Mitylene and took 120 to meet the new fleet. In the battle of Arginusae that followed, we find a complete reversal of the old tactics, the Spartan fleet sailing one deep and aiming at the *diekplous*, while the Athenians massed their weight in the wings to defeat it. But all order was soon lost, and an individual struggle followed, in which the Spartans were defeated and Callicratidas was killed. In his honesty and straightforwardness Callicratidas was a Spartan of the old type, but with advanced Pan-Hellenic sympathies.

See Xen. *Hell.* I., vi. 1-33. Plut. *Lysander* 5-7.

**CALLICULA**, a historic mountain of Campania, Italy, some 4m. N.E. of Teanum (mod. Teano) (*q.v.*). After the victory of Trasimenus (*q.v.*) and the Roman failure to block Hannibal's (*q.v.*) march into Picenum at the pass of Plestia, the Carthaginian army remained at rest in Picenum for some time, and then marched along the Adriatic coast into northern Apulia, encamping first near Luceria and then near Vibinum (Bovino). The dictator, Q. Fabius Maximus, encamped near Aecae (Troia), about 6 miles away from him, and when Hannibal offered battle, wisely refused it. Hannibal, therefore, who had no supply or recruiting base, and was living from hand to mouth, crossed the Apennines for the third time in the same year (217) and marched into Campania plundering the territory of Beneventum and taking the town of Telesia on his way down the valley of the Calor (mod. Calore) and up that of the Volturnus (mod. Volturno). Leaving the latter valley near Allifae he entered Campania by the defile below the ridge of Callicula, to the north-east of the modern village of Pietravairano, and plundered the Falernian territory. Unable to bring Fabius to battle, he planned to return to Apulia with the booty he had collected by the way by which he had come, but found it blocked by Fabius. Hannibal, however, collected 2,000 of the strongest

oxen among those he had captured, and after nightfall sent them off by a higher pass, crossing the ridge of Callicula in a westerly direction, with lighted torches tied to their horns, with a detachment of light troops, who had orders to make as much noise as possible. The Roman force which held the defile was completely deceived, left its position to pursue them, while Hannibal with the main body marched through the defile unhindered back to the

PLAN OF CALLICULA CAMPAIGNS 217 B.C.

valley of the Volturnus, and sent a detachment of light troops which successfully disengaged the light troops and the oxen.

Hence he marched through Samnium and into the country of the Paeligni, as though he were moving towards Rome, making Fabius keep between him and the city; and then he suddenly turned back and marched eastwards to Gerunium, Apulia, which is to be placed at Colle d'Armi, on the right bank of the Fortore some 20m. E.N.E. of Luceria and the same E.S.E. of Larinum—which he captured and used as a supply base, encamping outside the town and pillaging the countryside. The Romans eventually heard where he was, came up with him and established a camp on the left bank of the river, near Calene in the territory of Larinum. Both sides then advanced their camps closer to the river, so that each lay on a hill above it, but on opposite sides. Minucius, the master of the horse, who was in command in Fabius's absence, took advantage of the fact that the greater part of the Carthaginians were on a foraging expedition to attack their camp, and very nearly took it, so that Hannibal thought it more prudent to withdraw to his old camp near Gerunium itself, while Minucius occupied the abandoned camp on the right bank. Fabius now returned from Rome, and divided the army with him, each taking two legions; the camps were 1½m. apart and that of Fabius appears to have been on the left bank of the river. Between that of Minucius and that of Hannibal there was a hill and a deep ravine, in which the latter concealed 5,000 light troops and some cavalry; he then occupied the hill at dawn with a small force, and when Minucius attacked, as he expected, he sent continual reinforcements, and when the Romans were sufficiently engaged, threw in his reserves from both wings and the rear. A catastrophe was only avoided by the intervention of Fabius with his two fresh legions, and the Carthaginians sounded the retreat, Hannibal declaring that he had beaten Minucius, but that Fabius had beaten him. He had, indeed, succeeded in living on the country, so that in the next summer he was able to win the victory of Cannae; and he had sufficient self-restraint and self-confidence to be ready to wait for a decisive battle until the circumstances were favourable to his tactics of surrounding the enemy.

\* See Kromayer, *Antike Schlachtfelder*, iii. 1 (Berlin, 1912) for a full description of these operations in which it is once more clear that Polybius' authority is to be preferred to that of Livy. (T. A.)

**CALLIGRAPHY** is the art of fine writing. Writing is a means of communication by agreed signs; if these signs or symbols are painted or engraved on wood or stone we have that extension and application of writing known as *lettering*, i.e., a large script generally formed with mechanical aids such as the

BY COURTESY OF (1, 6) THE PEGASUS PRESS, "A NEWLY DISCOVERED TREATISE ON CLASSICAL LETTER DESIGN" (FACSIMILE BY STANLEY MORISON)

## CALLIGRAPHY FROM THE 15TH TO THE 17TH CENTURY

1. Excerpt from "Damianus Moyllus, Alphabetum," the first known printed work on letter-formation, Parma, 1480. Facsimile by Stanley Morison from "A Newly Discovered Treatise on Classical Letter Design"
2. From a writing-book by Giovannantonio Tagliente, Italian, 1525
3. Specimen from the first copybook of script, written by Ludovico degli Arrighi, surnamed Vioentino, and published 1522. Facsimile by Stanley Morison
4. Excerpt from Lodovico Curlione, "Il teatro delle cancelleresche corsive," Rome, 1594
5. Eustachio Cellerbrino; specimen of Italian semi-gothic hand used by legal and commercial classes. Very rare. One copy in a private library in New York and one in Berlin
6. Excerpt from John Ayres, "Tutor to Penmanship," London, 1698. Facsimile by Stanley Morison, from "Caractères de l'Ecriture dans la Typographie"

rule, compass and square. But it is the essence of handwriting that it be free from such, though not from all, government; and of beautiful handwriting that it possess style. When the agreed forms, passing through a mind sensitive to symmetry, are expressed upon vellum, paper or other suitable material by an instructed hand with an appropriate tool, the result may be a handwriting possessing style. Calligraphy may be defined as freehand in which the freedom is so nicely reconciled with order that the understanding eye is pleased to contemplate it. Hence we immediately recognize the beauty resulting from right proportion of the components to the whole of a letter, and between the parts to the whole of a word. Many scripts of the remote or recent past, such as the Rustic Capitals, Uncial, Half-Uncial, Quarter-Uncial, the Caroline Minuscule and the later Gothics, demonstrate that handwriting, though an elementary craft, is capable of infinite variations. Changes of fashion so affect the form, the cutting of the tool and the manner of holding it, that a collection of the hands employed in pre-Renaissance Europe exhibits a series of almost bewildering variations. The necessity for speed is the first great cause of variation; a second equally potent occasion lay in the use of special hands for certain purposes. In the mediaeval period, outside the monastic scriptoria where the most formal upright and deliberate text hands were written, there were several recognized classes occupied with writing such as clerks, public scribes, public notaries and in addition certain others who were ancestors of the later professional writing-masters. Finally, there were writers of the special hands used in documents issued from the papal and other chanceries. Most of these classes, in the hope of preventing forgery, wrote hands of deliberate complexity.

**The Renaissance**, by its reaction from the complicated late Gothic and reversion to the simpler Caroline hands, indeed changed the writing tradition of all Europe, but not all the alpine countries adopted the new hands simultaneously—the tenacity, in fact, of Gothic is only in our own day being broken in its chief stronghold, Germany. Though the humanists deliberately reverted to the Caroline hand, theirs was not a barren facsimile of the 9th century letter for, since they laboured for a return to classical traditions, many scribes broke completely with the Caroline exemplars in the matter of majuscules, so that adaptations of the old Roman geometrically formed inscription letters appear upon the vellum pages of humanistic codices equally with majuscules based upon the fine Tours forms.

The Renaissance did more than merely revert to the art styles of antiquity. In its early phase it was a movement in which a limitless curiosity of the mind—the mark of the true humanist—predominated and had not yet aroused the jealousy of the church. Indeed in the early 15th century, ecclesiastics vied with secular scholars in the task of renewing art and science. To record our least legacy of that age, we make acknowledgement to the secular humanistic scribes for the fine round book letter which is the foundation of our “roman” printing; to the scribes of the papal chancery for our running hand. In an age in which science, religion and art were the chief, and commerce a subordinate interest, these novel scripts were introduced and propagated by artists and ecclesiastics, while merchants, bankers and lawyers kept accounts and indited conveyances in a tortuous Gothic. The development of handwriting owes nothing to commerce until the next century, and then everything.

In mediaeval society it depended upon the officials of Church and State. Hands were invented and books written in accordance with liturgical, administrative and judicial requirements. Like other courts, the Roman *Curia* maintained (and maintains) a group of canon lawyers and scribes known as the Apostolic Chancery from which were issued papal bulls, and later a more modest class of document. A small easily formed hand was reserved by order of Pope Eugenius IV. (1431–47) for the engrossing of these minor documents written fast (*breui manu*) and known as “briefs.” The script itself became famous as “*cancelleresca corsiva*,” chancery cursive, and in the next century printed and engraved models of it abounded.

The first works on letter formation deal with capital letters and were compiled by enthusiastic admirers of the old Latin inscriptions, like Ciriaco of Ancona, who transcribed, collated and copied all the memorials, gravestones and tablets they could discover. Andrea Mantegna introduced into his famous frescoes at the Eremitani in Padua careful renderings of certain inscriptions (since destroyed). Feliciano of Verona compiled a collection of inscriptions and dedicated it to Mantegna; and from the same scholar's hand we have (Cod. Vaticanus 538) a codex which represents the earliest extant treatise on the shapes of inscription letters. The ms. is dated 1463 and is the first to give diagrams and instructions for the geometrical formation of Roman capitals.

The earliest printed work of the kind is a modest anonymous work with an undated colophon: “*impressum Parme per Damianum Moyllum, Parmensem.*” As there are extant several mss. signed by Damiano Moille we may guess that he had a share in the authorship as well as in the printing of the alphabet. There is bibliographical evidence for concluding the date of publication to lie between 1480–83.

At about the same time the friar and mathematician Pacioli, notable as a friend of Leonardo, was busy on his *De Divina Proportione*, a treatise which included an appendix on the geometry of letter-making. The Padre's book was not printed until 1509, but existed in a finely illuminated manuscript copy much earlier, having been presented to Ludovico Sforza (*Il Moro*) of Milan.

Fanti of Ferrara brought out in 1514 the first extension of the geometrical method to the rounded Gothic letter then greatly used for large choir-books: *Theorica et practica Perspicassimi Sigromundi de Fantis . . . De Modo Scribendi Fabricandique omnes Litterarum species* (Venice, Rubeus, 1514). The title is fuller than the contents, for Fanti gives no more than the Roman capitals in the method of Feliciano, Moille and Pacioli, plus a set of round semi-Gothic letters similarly made, which designs were roughly cut on wood by da Carpi. Whereas the models of capitals already published had been useful to architects and antiquarians and a few scribes, Fanti's small Gothic letters (lower case) of the kind then known as “modern letter” (*lettera moderna*) were serviceable to the numerous clerks in monasteries and elsewhere. Arrighi, a calligrapher from Vicenza and subsequently an assistant in the Apostolic Chancery, published in 1522 a book of models of a current correspondence hand based upon the *lettere de breui*. This, the first of all copybooks, was entitled *Il Modo et Regola da Imparare di scriuere littera corsiva ouer cancellerescha nouamente composto per Ludovico Vicentino*. The script in this first publication of Arrighi, *scrittore de breui apostolici in Roma*, as he styles himself, is a singularly effective and beautiful combination of the neo-Caroline minuscule, slightly inclined by speed, with perpendicular majuscules reminiscent of the inscriptions, whose austerity is relieved with additional characters of a decorative form, *BCDEPRN*. There are also

to be found flourishes, ligatures, initial and terminal letters of grace and freedom. Arrighi's fine professional hand is ornamental in comparison with the somewhat angular and pinched version of the same hand as it was officially used 50 years before. The popularity gained by the chancery script during the half-century 1470–1520 exposed it to great risks. Writers of diplomatic documents practised it with a discretion foreign to the temper of Mantegna, Cellini, da Vinci and scores of other artists, nobles and scholars who adopted it. The habit of writing “private” letters with a view to their being handed about as specimens of true Latinity developed interest in calligraphy, and with this powerful support the new cursive rapidly became the favourite correspondence script of the fashionable classes, absorbing a multitude of mannerisms which corrupted it until its original simplicity was scarcely recognizable. While in Vicentino's specimens flourished forms were offered as an occasional pleasant alternative to the rigid capital and both were modestly proportioned to the height of the ascending letters *d*, *h* and *l*, later models exhibit an irritating superfluity of display. The burin of the copper engraver produced an excessively brilliant line which tempted pupils to employ a correspondingly fine pen, so that

<sup>1</sup>Mas Latrîe (*Trésor de Chronologie*).

the later writing of the century was dominated rather by the technique of the engraver's burin than that of the scribe's pen. The first book in copper-plate is the handsome and ornate, though practical, *Libro* of Hercolani, a notary of Bologna (1571).

His book is valuable as a good specimen of the late chancery hand distinguished by its decorative treatment of the ascending and descending letters. In the pure Vatican style these forms terminated in an angular serif, which existed side by side with a variety which terminated in a short blunt curve from right to left. The angular serif went out of use before 1520 and thereafter no models of the chancery hand for secular or official Vatican use recommend it.

Gradually, by means of a fine pen and a supple wrist, the originally unassuming serif was turned into the most conspicuous feature in the word—and in the page—so that a late Italian 16th century letter is almost a network of deliberately formed blots. This development may be conveniently watched in the books of Palatino, a first-rate scribe who gained great renown in Spain where he was copied by Ycia. Pens then became finer and enabled Periccioli (Siena 1610) not only to execute very delicate calligraphical *entrelac* borders but exceedingly subtle script which gained a seductive sparkle when reproduced from intaglio plates. All the Italian scripts found their way abroad; the fine early hands and their bulbous successors may be met in various parts of Europe. The Italian artists transplanted to Fontainebleau by Francis I. included a humbler rank of decorators, craftsmen and calligraphers. These found Gothic, formal and cursive, generally practised. Tory wrote an Italian hand and his *Champ-fleury* a plea for beautiful lettering and an elaboration of the geometrical method of making Roman capitals he had learned from Pacioli and Dürer. Gothic book hands are also given, but we have to wait a generation for a French pattern book of correspondence hands. In the books of Hamon and de la Rue we find good chancery models and a number of *Lettres de Fantaisie* (alphabets of wavy, crooked, club-footed and other similarly treated latins). *Cursive françoise*, as current Gothic was called, always appears in the early French books. This was the letter from which the *Civilité* type was made, and which in the next generation was to be amalgamated with the Italian hand producing the elegant compromise known as "Ronde." It has a vigorous character and may rank as the French national hand, still employed to-day, but with its Gothicisms heavily diluted. Early fine Rondes are to be found in the book of Louis Barbedor (1628).

In the middle of the 17th century, Colbert, when Louis XIV.'s financial secretary, took in hand the revision of French official scripts and, in consequence, the clerks in the offices of State were instructed to abandon the old Gothic cursives and to confine themselves to the upright Ronde known as *financière*, inclined *bâtarde*, and a running form known as *coulée*.

Such changes gained effect gradually: generations of masters recommended almost non-Gothic as the "Italian hand," so great was the prestige of that name. The rise of the fine French school of portrait engraving influenced the use of Roman scripts and the opposition of Colbert left Gothic scarcely a vestigial existence by the end of the century.

To Colbert, the eminent master Senault dedicated his fine book—*Livre d'écriture représentant la beauté de tous les caractères financiers maintenant à la mode* (1660). Other French models of calligraphy circulated also in England and in Holland; French influence in England being more direct than the Italian, though there were such Italians as Petruccio Ubaldini who taught calligraphy to the English Court (c. 1580). Jean de Beauchesne and John Baildon's *A Booke containing divers sortes of hands*, also a "*True and just proportiō of the capitall Romae*" (London, Thomas Vautrouillier, 1571) is the first English manual of calligraphy. Beauchesne is the same who had brought out *Le Thresor d'Esriture* in Paris (1550). Both contained admirable models; the English book having handsome forms of current Gothic and secretary hands as well as fine italics.

Billingsley's *The Pen's Excellency* (London) still has many more secretary, court and other Gothic hands than Roman.

Billingsley's is one of the few English books independent of the designs of Barbedor and Materot which powerfully affected London masters of the 17th century. But though England learned much from France, specimens of the work of Van der Velde, Boissens, Perlingh and other conspicuous Dutch exponents of the art were highly esteemed when the London writing-masters found their services demanded by youths training for clerkships in the growing English commercial houses. The Dutch possessed at that time most of the carrying trade and were for that reason directly imitated in England. The Dutch naturally copied the Frenchmen since French literature was not only read but, owing to the repressive legislation against Paris printers, also printed in the Low Countries.

The difference between the late Italian 16th, early French and Dutch 17th century hands was not considerable—mainly a matter of width of letter. The Italians had a habit of angularizing the letter, the Dutch of widening and giving it greater inclination. What French, Dutch and English writers commonly called the "Italian" hand is a free, flowing and obviously inclined hand in which the ascenders are looped and the majuscules entirely cursive—wholly different from the Chancery of Vicentino. This was the result of the demand for speed, itself the concomitant of commercial development.

English writing gained in currency as commerce expanded. When in 1658, Oliver Cromwell broke the Dutch commercial power and, by his Mercantile Act, secured that every cargo shipped to England was carried in English bottoms, there resulted a vast increase in the nation's shipping. Commercial clerkships became desirable positions, bringing a fine opportunity for such professors as Snell (1693), Seddon (1695) and others who all learned from the Dutch masters, but whose hands drew away from their models and finally expressed those characteristics which came in another generation to be regarded by the rest of the world, if not by Englishmen, as thoroughly English and admirable for the purposes of salesmanship. Thus the commercial success of England drew hearty foreign respect for the script in which English Bills of Lading and Notes of Exchange were made out; named *Anglaise* in France, *letra Inglesa* in Spain, it dominated in Italy itself at the end of the 19th century as "*Lettere Inglese*." Gothic now persists only with the greatest difficulty—where once it had been used for the text of deeds it fights for existence as a script for titles, and to-day *Whereas* and *This Indenture* witnesseth its sole traces.

In contemporary France the *ronde* is being hard pressed by *anglaise*. The *Cours d'Inscription Calligraphique*, published by École des Travaux Publics has a very extensive circulation, and though treating of *bâtarde* and *ronde* gives primary place to *anglaise*.

The situation is not very different in present-day Spain. The magnificent 16th century specimens of Iciar (1550) and Brun (1583) were adaptations of the hand of Palatino and Vicentino, but these writers succeeded neither in acclimatizing these nor inventing any new, living, national hands. This was achieved by Lucas, who created a characteristic Spanish upright round-hand and companion inclined *bâtarde* which with astonishingly trifling variations remained in possession for two centuries, giving way only before *anglaise*. The hands of many English writing-masters were familiar to the leading Spanish calligraphers of the 18th century. It would be an exaggeration to claim that the script, which we are accustomed to term "copper-plate," possesses an attractive personality. It is colourless, thoroughly unromantic and dull. These, however, were precisely the qualities which commended it to those who wrote out invoices. Above all it was expeditious, and the writing-masters of London knew better than to teach them to tricking out of ascenders with solid blacks or capitals with meandering loops which a generation of earlier masters thought would endear their own calligraphy to present and future. The simple and practical nature of English business hand did not exactly serve the material interests of the English writing-master. Plain round-hand is not so difficult to acquire as to need either perpetual practice at home or continual resort to a master. The early American colonists followed the calli-

COPY No. 1. *After* WINCHESTER FORMAL WRITING about 975 A.D.

Et haec scribimus  
vobis ut gaudeatis,  
et gaudium ves-  
trum sit plenum.  
Et haec est annuntiatio, quam  
audivimus ab eo, et annunciamus  
vobis: Quoniam Deus lux est,  
& tenebrae in eo non sunt ullae.

Note: This copy is written with a pen, not printed. E. Feb. 1918. A.D.

the direction in which it moves. The strokes are generally begun downwards or toward the left or in forms of several curves (the pen being left after each stroke); thus a curve of two strokes, the first a large curve down, the second a short curve forward. Then again the "x" (an "x" of four) is made by *three* strokes, 1st, a short curve

Hand-mixed steel pens and Reeds may be used. Quill pens are very good but require special cutting. How to cut Quill and Reed pens is to be learned from my Handbook "Writing & Illuminating, & Lettering" (John Rogers, London, 1895, 6d. net) besides how to make MS. Books and to write in colour. Edward Johnston, *Ditching, Surrey.*

THIS SHALL BE PUBLISHED BY DOUGLAS PLEPLER at HAMPSHIRE HOUSE HAMMERSMITH  
1916 A.D.

 Wombesta Formed M.C. very slightly modified

## EXAMPLES OF CALLIGRAPHY FROM THE 16TH TO 20TH CENTURY

1. Excerpt from "A Book Containing Divers Sorts of Hands," the first English manual of calligraphy, written in 1571 by John Balldon and Jean de Beaulchesne, showing the influence of early French script
2. Spencerian or semi-angular penmanship engraved about 1857 by Gerlack, and published by Plunney and Company, Buffalo, N. Y.
3. Specimen of penmanship from Martin Billingsley's *The Pen's Excellencies or the Secretaries Delight*, 1618, showing Gothic influence
4. A copy of an engraving by Charles Snell in *The art of writing in its Theory and Practice*, published in London in 1712
5. Copy sheet from Edward Johnston's manuscript illustrating his particularly handsome type of calligraphy, a blend of roman and italic hands introduced at the beginning of the twentieth century
6. Illustration from *The Fashionable Penman*, showing the method of handwriting advocated by Joseph Carstairs. According to this system, the forearm, not the fingers, controlled the script

graphical styles of the home country and Benjamin Franklin practised a fine *anglaise* from which a printing type was subsequently engraved. The first American copybook (Jenkins, 1791) continued the mid-18th century English script. In 1809 Joseph Carstairs of London championed a theory of handwriting in which the forearm and not the fingers controlled the script. His book was translated into French and Spanish and was introduced into the United States by Foster in 1830. It was employed overseas with such success that it even became known as the American System. The American hand,<sup>1</sup> however, did in fact develop from a continuation of this movement of the forearm and a condensation of the running hand exemplified in Jenkins. Dayton copyrighted in 1855 the first specimen of what developed into a style which now may fairly claim to rank as the national American hand. It is a style which requires a very fine pen as the down strokes taper from top to bottom. There is a slightly increased slope, a tendency to flourished terminations and a noticeable degree of condensation. It had little success at first and it is possible that it would have made no progress but for the plagiarization by the very active "Professor" Spencer, who, in spite of the protests of Dayton, claimed the design as his own and taught it throughout a chain of business colleges established in 44 cities by the time of his death in 1861. The style which is known to this day as the Spencerian system is by no means without its exponents. It is not a particularly unpleasant letter except when written carelessly.

Nineteenth-century England learned to write from the copybooks of Vere Foster, whose lithographed models expressed edifying admonitions in a flawless current hand of the plainest style. The "Civil Service" hand also, an upright version of the same design, was and is commonly practised. Both scripts are declining, for one thing because when written with great speed they become illegible. The pressure of life to-day tells heavily against decent handwriting. Writing too much and therefore too quickly we corrupt the shape and become accustomed to low standards. We may find a way out by practising two hands, a rough scribble and a ceremonial script. Twentieth-century mechanics ensure a future for correspondence calligraphy if the desk equipment of every schoolboy and girl could include a typewriter.

To inculcate a good modern current hand Mr. Hewitt's *Oxford Copy Books* are to be recommended.

So much for the epistolary department of post-Renaissance calligraphy (the early fine formal book hands may be studied in the article on PALAEOGRAPHY: *Latin*). Calligraphical book hands settled the forms of the earliest printing types, but were themselves affected when the type forms acquired a momentum of their own. It is not true that typography killed calligraphy outright—some of the finest calligraphy in the history of book production was executed within the memory of the generation which witnessed the invention of printing, as may be seen from the work of Antonio Sinibaldi of Florence and Mennius of Naples, to name only two famous scribes of the Italian school. The anonymous calligrapher whose splendid "Chantilly" *Caesar* is fit to rank with the finest of mediaeval manuscripts, heads a not less brilliant French school. The art died for lack of patrons, not for lack of calligraphers. These eked out a penurious existence as rubricators attached to printing houses, or as engrossers of choir-books which required larger characters than type foundry were willing to cast.

The age of Louis XIV. witnessed an abortive revival of calligraphy to which the manuscripts by Jarry, Gilbert, Damoiselet and Rousselot remain a pathetic testimony. This school so formalized their book hands and cursives as to deceive the eye into thinking that they were types. Scribes like Eclabart were in fact able to write whole books in a letter indistinguishable from printing type.

Gothic remained here and there in occasional use and, even in our own day, it not infrequently garnishes a presentation address. Col. Lindbergh's reception by the City of New York in 1927 was signaled by the presentation of a gorgeous address of welcome in which the regard of the American nation was tendered in a

text comprising four or five cacophonous Gothics, semi-Gothics and Romans. If in any English address the calligraphy has been handsome and noble or even sober and dignified, it will have been due entirely to the teaching and practice of Mr. Edward Johnston whose *Writing and Illuminating and Lettering* (London, 1906) created a new interest in calligraphy among wealthy amateurs and collectors and a new school of excellent scribes. To Mr. Johnston's teaching therefore we owe that revival of fine calligraphy in which England may well take great pride. Mr. Johnston did what the renaissance had done before him: he went back to the Caroline Minuscule and though he learned, and learned well, from certain fine English mediaeval hands his own beautiful book-hand is individual and underived. As the Exhibition of the Society of Scribes and Illuminators (London) proves, he has created a body of skilful English calligraphers, whose fine scripts give us no excuse for using the debased Gothics and pinchbeck Romans laboriously concocted by the hack employees of the west-end heraldic artist, the court stationer and the Fifth-Avenue bookseller.

Johnston's influence has not been merely national; it has perhaps been greatest in Germany. The works of Neff, Dürer and of Baurenfeind were succeeded by an indifferent posterity and until our own generation Germany used a mean informal Gothic for commemorative and other purposes where a ceremonial writing was required. In 1910 Mr. Edward Johnston's pupil Fräulein Simons introduced his teaching into Germany with great success and the printing revival due to William Morris which had already made rapid progress rallied to its support. In 1928 Germany has a school of calligraphers second to none in inventiveness and skill. The Gothic letter does not lack champions: the Austrian Professor Larisch and Herr Otto Hupp, two of the generation who were writing before Mr. Johnston's movement assumed its present importance, both practised Gothic. Prof. Koch of Offenbach is a representative of the present lively generation and for a variety of national and other reasons prefers to work in Gothic, though he learned from Johnston the handsome Roman and italic hands. F. H. Ehmcke, though skilled in Gothic, specializes in Roman. There are not wanting certain influences in Germany which while seeking inspiration from the new movement would be happier if the old Gothic hands could be revived. Thus the *Bund für Deutsche Schrift* exists to encourage the Gothic hands. It remains to be seen whether this reaction will be successful.

There is perhaps a tendency on the part of the Johnstonian school to narrow its interest and practice to formal book-hands and to ignore the need for a simple, easy, running cursive. The layman fears that if he writes with a modicum of care his script will be confounded with his office boy's, and it is even claimed that "character" in handwriting is more important than legibility. This is a *reductio ad absurdum* and it may be replied that a self-respecting person employing the inevitable and natural movement of his pen to make modest capitals and a lower-case script in which the angles shall be regular, the characters symmetrically rounded, the descenders and ascenders proportionate to their bodies will there and then have the elements of legibility, style and character.

**CALLIMACHUS**, an Athenian sculptor of the second half of the 5th century B.C. Ancient critics associate him with Calamis. He is given credit for two inventions, the Corinthian column and the running borer for drilling marble. He made a golden lamp for the Erechtheum (Paus. I. xxvi., 2). His "dancing Laconian maidens" was a work "of flawless precision" but spoilt, like his other sculptures, by over-elaboration of detail. (Pliny, *Nat. Hist.*, xxxiv. 92.)

See A. Furtwängler (trans. E. Sellars), *Masterpieces of Ancient Sculpture*, p. 437 ff. (1895).

**CALLIMACHUS**, Greek poet and grammarian, a native of Cyrene, flourished about 250 B.C. He opened a school in the suburbs of Alexandria, and some of the most distinguished grammarians and poets were his pupils. He was subsequently appointed by Ptolemy Philadelphus chief librarian of the Alexandrian library, which office he held till his death (about 240). His *Pinakes* (tablets), in 120 books, a critical and chronologically arranged catalogue of the library, laid the foundation of a history of Greek literature. Of his 800 works, only six hymns, 64 epigrams and some fragments are extant; a considerable fragment of the *Hekale*, an idyllic epic, has also been discovered in the Rainer papyri (see Kenyon in *Classical Review*, Nov. 1893). His *Kome Berenikes* is known from the imitation of Catullus and partly in Greek from papyrus fragments (cf. *Classical Philology* for 1929). His *Aitia* (causes) was a collection of elegiac poems. According to Quintilian (*Instit.* X. i. 58) he was the chief of the elegiac poets, and imitated by Ovid, Catullus and especially Propertius. The extant hymns are extremely learned, and written in a laboured style, unrelieved by poetic genius. The epigrams are in the Greek anthology.

**BIBLIOGRAPHY.**—Editions of the hymns, epigrams and fragments (the last collected by Bentley) by J. A. Ernesti (1761), and O. Schneider (1870-73) (with elaborate indices and excursuses); E. Cahen, French edition, with introductions (1922); hymns and epigrams, by A. Meineke (1861), and U. Wilamowitz-Möllendorff (1897). See *Neue Bruchstücke aus der Hekale des Kallimachos*, by T. Gomperz (1893); H. von Arnim, *Zum neuen Kallimachos* (Wien, 1910); R. Pfeiffer, *Callimachi Fragmenta Super Reperta* (1921), with bibliography; F. Schmidt, *Die Pinakes des Kallimachos* (1922); also G. Knaack, *Callimachea* (1896); A. Beltrami, *GP Inni di Callimacho e il Nomo di Terpendro* (1896); K. Kuiper, *Studia Callimachea* (1896); A. Hamette, *Les Épigrammes de Callimaque: étude critique et littéraire* (Paris, 1907); U. von Wilamowitz-Möllendorff, *Hellenistische Dichtung in der Zeit des Kallimachos* (1924). There are English translations (verse) by W. Dodd (1755) and H. W. Tytler (1793); (prose) by J. Banks (1856). See also J. E. Sandys, *Hist. of Class. Schol.* i. (ed. 1906), p. 122.

**CALLINUS** of Ephesus, the oldest of the Greek elegiac poets and the creator of the political and warlike elegy. He is supposed to have flourished between the invasion of Asia Minor by the Cimmerii and their expulsion by Alyattes (630-560 B.C.). During his lifetime his own countrymen were also engaged in a life-and-death struggle with the Magnesians. These two events

give the key to his poetry in which he tries to rouse the Ionians to patriotism. Only scanty fragments of his poems remain; the longest of these (preserved in Stobaeus, *Florilegium*, li. 19) has even been ascribed to Tyrtaeus.

See edition of the fragments by N. Bach (1831), and in Bergk, *Poetae Lyrici Graeci* (1882). On the date of Callinus, see the histories of Greek literature by Mure and Mueller; G. H. Bode, *Geschichte der hellenischen Dichtkunst*, ii. pt. i. (1838); and G. Geiger, *De Callini Aetate* (1877), who places him earlier, about 642.

**CALLIOPE**, the chief of the Muses (q.v.), occasionally in late authors the Muse of epic poetry (Gr., "beautiful voice"). See Hesiod, *Theog.*, 79; *Anth. Pal.*, ix. 504, 1.

**CALLIRHOE**, in Greek legend, second daughter of the river-god Achelous and wife of Alcmaeon (q.v.). On his death, she prayed that her two young sons might grow to manhood at once and avenge their father. This prayer was granted; and her sons, Amphiaraus and Acarnan, slew Phegeus, the murderer of Alcmaeon, and returning with the necklace and robe (*peplos*) of Harmonia (q.v.; see also *ALCMAEON*), dedicated them at Delphi (Ovid, *Metam.* ix. 413).

**CALLISTHENES** (c. 360-328 B.C.), of Olynthus, Greek historian, a relative and pupil of Aristotle, through whose recommendation he was appointed to attend Alexander the Great in his Asiatic expedition. He censured Alexander's adoption of oriental customs; this offended the king, and he was accused of being privy to a conspiracy and thrown into prison, where he died. His death was commemorated in a treatise (*Καλλισθένης ἡ περὶ πένθους*) by his friend Theophrastus. Callisthenes wrote an account of Alexander's expedition, a history of Greece from the peace of Antalcidas (387) to the Phocian War (357), a history of the Phocian War and other works, all of which have perished. The romantic life of Alexander, the basis of all the Alexander legends of the middle ages, originated during the time of the Ptolemies, but in its present form belongs to the 3rd century A.D. Its author is usually known as pseudo-Callisthenes, although in the Latin translation by Julius Valerius Alexander Polemius (beginning of the 4th century) it is ascribed to Aesopus; Aristotle, Antisthenes, Onesicritus and Arrian have also been credited with the authorship. There are also Syrian, Armenian and Slavonic versions, in addition to four Greek versions (two in prose and two in verse) in the middle ages (see Krumbacher, *Geschichte der byzantinischen Literatur*, 1897, p. 849). Valerius's translation was completely superseded by that of Leo, arch-priest of Naples in the 10th century, the so-called *Historia de Preliis*.

See *Scriptores rerum Alexandri Magni* (by C. W. Müller, in the Didot edition of Arrian, 1846), containing the genuine fragments and the text of the pseudo-Callisthenes, with notes and introduction; A. Westermann, *De Callisthene Olynthio et Pseudo-Callisthene Commentatio* (1838-42); J. Zacher, *Pseudo-Callisthenes* (1867); W. Christ, *Geschichte der griechischen Literatur* (1898), pp. 363, 819; article by Edward Meyer in Ersch and Gruber's *Allgemeine Encyclopädie*; A. Ausfeld, *Zur Kritik des griechischen Alexanderromans* (Bruchsal, 1894); Plutarch, Alexander, 52-55; Arrian, *Anab.* iv. 10-14; Diog. Laërtius v. 1; Quintus Curtius viii. 5-8; Suidas s.v. See also *ALEXANDER THE GREAT* (*ad fin.*). For the Latin translations see Teuffel-Schwabe, *Hist. of Roman Literature* (Eng. trans.) § 399; and M. Schanz, *Geschichte der römischen Literatur*, iv. 1, p. 43.

**CALLISTHENICS**: see GYMNASTICS; PHYSICAL CULTURE.

**CALLISTO**, in Greek mythology, an Arcadian nymph, daughter of Lycaon and companion of Artemis; probably a local form of Artemis *Kalliste* (fairest). She bore Zeus a son, Arcas, the ancestor of the Arcadians, and was transformed into a bear by Hera, Zeus, or Artemis. Arcas, when hunting, encountered the bear Callisto, and would have shot her, had not Zeus carried up both to the skies, where he placed them as constellations.

**BIBLIOGRAPHY.**—See Apollodorus, iii. 100-101; Ovid, *Metam.*, ii. 381-530; R. Franz, *De Callistis fabula* (1890), which deals exhaustively with the various forms of the legend, and Roscher's *Lexikon*, s.v.

**CALLISTRATUS**, an Athenian poet, only known as the author of a hymn in honour of Harmodius (q.v.) and Aristogeiton. This ode, which is to be found in Athenaeus (p. 695), has been beautifully translated by Thomas Moore.

**CALLISTRATUS** of Aphidnae, Athenian orator and general in the 4th century B.C. For many years, as *prostates*, he supported Spartan interests at Athens. On account of the refusal of the

Thebans to surrender Oropus, which on his advice they had been allowed to occupy temporarily, Callistratus, despite his magnificent defence (which so impressed Demosthenes that he resolved to study oratory), was condemned to death, 361 B.C. He fled to Methone in Macedonia, and on his return to Athens in 355 he was executed.

See Xenophon, *Hellenica*, iii. 3, vi. 2; Lycurgus, *In Leocr.* 93; and P. Cloché, *La Politique de l'Athénien Callistratos*, in *Revue des Études Anciennes*, vol. xxv. (Bordeaux, 1923), where references are given to other modern works.

**CALLISTRATUS**, Alexandrian grammarian, flourished at the beginning of the 2nd century B.C. He was one of the pupils of Aristophanes of Byzantium. Callistratus wrote commentaries on Greek poets, a few fragments of which have been preserved in the scholia and in Athenaeus. He was also the author of a miscellaneous work called *Συμμικτά*, used by the later lexicographers, and of a treatise on courtesans (Athenaeus iii. 125 B, xiii. 591 D). He is not to be confused with Callistratus, the pupil and successor of Isocrates and author of a history of Heraclea in Pontus.

See R. Schmidt, *De Callistrato Aristophaneo*, appended to A. Nauck's *Aristophanis Byzantii Fragmenta* (1848); also C. W. Müller, *Fragmenta Historicorum Graecorum*, iv. p. 353 note.

**CALLISTRATUS**, Greek sophist and rhetorician, probably flourished in the 3rd century. He wrote *Ekphraseis*, descriptions of 14 works of art in stone or brass by distinguished artists. This little work is usually edited with the *Eikones* of Philostratus.

**BIBLIOGRAPHY.**—See F. Jacobs, *Animadversiones criticae in Callistrati statuas* (1797); edition by Schenkl-Reisch (Teubner series, 1902); also C. G. Heyne, *Opuscula Academica*, v., pp. 196–221, with commentary on the *Descriptiones*.

**CALL MONEY.** A London money-market term used to describe short-term loans advanced to bill-brokers by banks on security. Another name for such advances is "day-to-day money," or even "over-night money." Such advances are essential to the bill-broker, who requires prompt loans to deal with bills offering. Call money is advanced on the security of bills of exchange or of bearer securities, and the name expresses the fact that, lent for a very short period, the bank making the advance has the money for practical purposes at call. (See **MONEY MARKET**.)

**Call Loan.**—According to the custom in use by the New York Stock Exchange, a lender wishing repayment of a call loan must notify the borrower by 12.30 P.M. in order to receive payment on that day, and a borrower wishing to terminate a call loan must notify the lender before 1 P.M., or else he can be charged another day's interest. It is possible to stipulate a rate of interest on a call loan but this practice is quite unusual. Interest is commonly paid at the "call loan rate," which may vary from day to day. The lender notifies the borrower of any rise or fall in the interest rate, which is known as "marking up rates" or "marking down rates."

**CALLOT, JACQUES** (1592–1635), French engraver, was born at Nancy in Lorraine, where his father, Jean Callot, was a herald-at-arms. When only 14 years old, he was allowed to accompany the duke of Lorraine's envoy to the papal court in order to study art in Rome. His first care was to study the art of design, of which in a short time he became a perfect master. Philip Thomasin instructed him in the use of the graver, which, however, he ultimately abandoned, substituting the point as better adapted for his purposes. From Rome he went to Florence, where he remained till the death of Cosimo II., the Maecenas of those times. On returning to his native country he was warmly received by the then duke of Lorraine, who admired and encouraged him. As his fame was now spread abroad in various countries of Europe, many distinguished persons gave him commissions to execute. By the Infanta Isabella, sovereign of the low countries, he was commissioned to engrave a design of the siege of Breda; and for Louis XIII. he executed a design of the siege of Rochelle and the attack on the Isle of Ré. He engraved in all about 1,600 pieces, the best of which are those executed in aqua fortis. No one ever possessed in a higher degree the talent for grouping a large number of figures in a small space, and of representing with two or three bold strokes the expression, action and peculiar features of each

individual. Freedom, variety and naïveté characterize all his pieces. His Fairs, his Miseries of War, his Sieges, his Temptation of St. Anthony and his Conversion of St. Paul are the best-known of his plates.

See also Edouard Méaume, *Recherches sur la vie de Jacques Callot* (1860).

**CALLWELL, CHARLES EDWARD** (1859–1928), only son of Henry Callwell, of Lismoyne, Antrim, was born in London on April 2, 1859, and educated at Haileybury. He entered the Royal Military Academy in 1876. He saw active service in India, in the Transvaal 1881, and in the South African War. He had resigned from the intelligence department of the war office, where he was D.A.Q.N.G. in that branch, in 1909, but returned to the service in 1914, held the post of Director of Military Operations at the War Office during the Great War and was largely responsible for the plans of the Dardanelles campaign, although opposed to it in principle. From 1915 onwards he was employed first in Russia and then on munitions work, and in 1917 was promoted major-general and created K.C.B. He was an acknowledged authority on small overseas campaigns, and his chief contribution to literature is his *Small Wars* (1897), which has remained a standard work. His other works include: *Tactics of To-day* (1897), *Military Operations and Maritime Preponderance* (1897), *The Tactics of Home Defence* (1897) and *The Dardanelles* (1920).

**CALMET, ANTOINE AUGUSTIN** (1672–1757), French Benedictine, was born at Mesnil-la-Horgne, on Feb. 26, 1672. He joined the Benedictines in 1688, and in 1698 was appointed to teach theology and philosophy at the abbey of Moyen-Moutier. He was successively prior at Lay, abbot at Nancy and of Sénonés in Lorraine. He died in Paris on Oct. 25, 1757. The erudition of Calmet's exegetical writings won him a universal reputation but they have failed to stand the test of modern scholarship. The most noteworthy are:—*Commentaire de la Bible* (1707–16), and *Dictionnaire historique, géographique, critique, chronologique et littéral de la Bible* (1720). His numerous other works and editions of the Bible are known only to students, but as a pioneer in exegesis, Calmet is noteworthy. As a historical writer he is best known by his *Histoire ecclésiastique et civile de la Lorraine* (Nancy, 1728), founded on original research, and by various useful works on Lorraine, of which a full list is given in Vigouroux's *Dictionnaire de la Bible*.

See A. Digot, *Notice biographique et littéraire sur Dom Augustin Calmet* (Nancy, 1860).

**CALMETTE, GASTON** (1858–1914), French journalist and writer, was born at Montpellier on July 30, 1858. In 1884 he joined the staff of *Le Figaro*, and in 1894 became editor. He attracted much notice in 1913 and 1914 as the originator of the bitter attacks on the policy of M. Caillaux; especially with regard to M. Caillaux's attitude in the Rochette case of 1911, in which it was alleged by *Le Figaro* that the director of public prosecutions had been influenced by the Ministry to delay the course of justice. As a result of these newspaper attacks Mme. Caillaux called at the office of *Le Figaro* on March 16, 1914 and shot M. Calmette dead. (See **CAILLAUX**, JOSEPH MARIE AUGUSTE.)

**CALNE** (Kawn), a market town and municipal borough in the Chippenham parliamentary division of Wiltshire, England, 99m. W. of London by the G.W.R. Pop. (1931) 3,463. Area, 356 acres. It lies in the valley of the Calne, and is surrounded by the high table-land of Salisbury Plain and the Marlborough Downs. In the 10th century Calne (*Canna, Kalne*) was the site of a palace of the West-Saxon kings. Here a synod met in 978 and a witenagemot was summoned in 997. In the Domesday Survey Calne was a royal borough with forty-seven burgesses. In 1565 the borough possessed a gild merchant. Calne claimed to have received a charter from Stephen and a confirmation of the same from Henry III.; the charter issued to the borough by James II. in 1687 apparently never came into force. The borough returned two members to parliament more or less irregularly from the first parliament of Edward I. until the Reform Bill of 1832. Other noteworthy buildings, besides the church of St. Mark, are a grammar school, founded by John Bentley in 1660, and the town-hall. Bacon-curing is the staple industry.

**CALOMEL** occurs in nature as the mineral horn-quick-silver, found as translucent tetragonal crystals with an adamantine lustre and whitish grey or brownish colour; it is mercurous chloride (mercury subchloride),  $\text{Hg}_2\text{Cl}_2$ . The chief localities are Idria, Obermoschel, Horowitz in Bavaria and Almaden in Spain. It was used in medicine as early as the 16th century under the names *Draco mitigatus*, *Manna metallorum*, *Aquila alba*, *Mercurius dulcis*; later it became known as calomel, a name probably derived from the Greek *καλός*, beautiful, and *μέλας*, black, in allusion to its blackening by ammonia, or from *καλός* and *μέλι*, honey, from its sweet taste. It may be obtained by heating mercury in chlorine, or by reducing mercuric chloride (corrosive sublimate) with mercury or sulphurous acid. It is manufactured by heating a mixture of mercurous sulphate and common salt in iron retorts, and condensing the sublimed calomel in brick chambers. In the wet way it is obtained by precipitating a mercurous salt with hydrochloric acid. Calomel is a white powder which sublimes at a low red heat; it is insoluble in water, alcohol and ether. Long continued boiling or prolonged digestion with water, dilute hydrochloric acid or solutions of alkaline chlorides convert it into mercuric chloride with deposition of mercury.

The molecular weight of mercurous chloride has given occasion for much discussion. E. Mitscherlich determined the vapour density to be 8.3 (air = 1), corresponding to  $\text{HgCl}$ . The supporters of the formula  $\text{Hg}_2\text{Cl}_2$  pointed out that dissociation into mercury and mercuric chloride would give this value, since mercury is a monatomic element. A. Werner determined the molecular weight of mercurous chloride in pyridine solution, and obtained results pointing to the formula  $\text{HgCl}$ . However, the double formula,  $\text{Hg}_2\text{Cl}_2$ , has been completely established by H. B. Baker, 1900, by vapour density determinations of the absolutely dry substance.

Calomel possesses certain special properties and uses in the pharmacology and therapeutics of mercury (*q.v.*). The specific value of mercurous chloride is that it exerts the valuable properties of mercuric chloride in the safest and least irritant manner, as the active salt is continuously and freshly generated in small quantities. Its pharmacopoeial preparations are the "Black wash," in which calomel and lime react to form mercurous oxide, a pill still known as "Plummer's pill," and an ointment. Externally the salt has not any particular advantage over other mercurial compounds, despite the existence of the official ointment. Internally the salt is given in doses—for an adult of from one-half to five grains. It is an admirable aperient, acting especially on the upper part of the intestinal canal (duodenum and jejunum). It is well to follow a dose of calomel with a saline purgative a few hours afterwards. The special value of the drug as an aperient depends on its antiseptic power and its stimulation of the liver. The salt is often used in the treatment of syphilis, but is probably less useful than certain other mercurial compounds. Calomel or alternatively mercurio-salicyl arsenate is the active constituent of an ointment (unguentum prophylaxis) employed as a prophylactic measure against syphilis.

**CALONNE, CHARLES ALEXANDRE DE** (1734–1802), French statesman, was born at Douai on Jan. 20, 1734. He became in succession advocate to the general council of Artois, *procureur* to the parlement of Douai, master of requests, then intendant of Metz (1768) and of Lille (1774). Calonne assumed office as controller-general of finance on Nov. 3, 1783. He found "300 millions to pay and neither money nor credit." He attempted to carry on the government by means of loans and thus made a position which was already serious practically hopeless. The parlement protested against registering the edicts for raising the loans, but in vain. In October 1785 he recoined the gold coinage, and he developed the *caisse d'escompte*. When it became impossible to raise any more loans Calonne proposed to the king the suppression of internal customs, duties, and the taxation of the property of nobles and clergy. Turgot and Necker had attempted these reforms, and Calonne attributed their failure to the malevolent criticism of the parlements. An assembly of "Notables" was called together in January 1787. Before it he exposed the deficit in the treasury, and proposed the establishment of a *subvention territoriale*, which should be levied on all property without dis-

tinction. This suppression of privileges was badly received by the privileged notables. Calonne, angered, printed his reports and so alienated the court. Louis XVI. dismissed him on April 8, 1787, and exiled him to Lorraine; from there he went to England. In 1789, when the states-general were about to assemble, he crossed over to Flanders in the hope of being allowed to offer himself for election, but he was sternly forbidden to enter France. He then joined the *émigré* party at Coblenz. His *Etat de la France à présent et à venir*, a violent criticism of the financial measures of Necker, was published in London in 1790. He was allowed to return to France in 1802, and died in Paris on Oct. 30 of that year.

See Ch. Gomel, *Les Causes financières de la Révolution* (1893); R. Stourm, *Les Finances de l'ancien régime et de la Révolution* (1885); Susane, *La Tactique financière de Calonne*, with bibliography (1902).

**CALOOCAN**, a municipality (with administration centre and 31 *barrios* or districts) of the province of Rizal, Luzon, Philippine Islands, not far from Manila. Pop. (1918) 19,551, of whom 61 were whites. The principal products of this fertile region are rice, sugar and coco-nuts. In 1918 it had 18 manufacturing establishments with output valued at 156,000 pesos and 52 household industry establishments with output valued at 20,800 pesos. It has 12 public schools. Caloocan was one of the earliest communities to rise against the Spaniards. The language is Tagalog.

**CALORESCENCE**. When radiant energy is absorbed by a substance (*i.e.*, when the sum of the reflected and transmitted energies is not equal to the incident energy) the absorbed energy is usually transformed into radiant energy of a different wavelength or refrangibility, or into energy of another form. The conversion of the rays belonging to the dark (infra-red) portion of the spectrum into the shorter, more refrangible waves of visible light was demonstrated by John Tyndall and the term *calorescence* (from the Lat. *calor*, heat) was invented by him to describe this phenomenon.

Tyndall sifted out the long, dark, infra-red waves from the shorter, visible waves associated with them in the light from the sun or electric arc, and concentrated them to a focus. A piece of charcoal or blackened platinum placed at this focus was raised to incandescence. The emission of light (visible rays) by the charcoal or platinum is purely a temperature effect, therefore calorescence is not to be regarded as the strict converse of the phenomenon shown by Sir G. G. Stokes to occur in fluorescent bodies (*see* FLUORESCENCE and PHOSPHORESCENCE).

See also John Tyndall, *Heat as a Mode of Motion*.

**CALORIC**, a hypothetical imponderable fluid to whose action the early scientists ascribed the manifestations of heat (*q.v.*).

**CALORIE** (also spelt CALORY). A unit of heat defined as the quantity of heat required to raise a unit mass of water one degree in temperature on the Centigrade scale, in which the freezing point of water is taken as 0°C. and the boiling point as 100°C. The magnitude of the unit is proportional to the unit of mass selected, so that it is also necessary to specify the unit of mass in defining the quantity of heat measured. The following units of this type are in general use for various purposes.

The *gramme-calorie* (or *small calorie*) defined as the quantity of heat required to raise the temperature of 1 gramme of water by 1°C., is the unit of heat most commonly employed for scientific purposes for which the gramme is taken as unit of mass. The *kilogramme-calorie* (*kilocalorie* or *large calorie*) is equal to 1,000 gramme-calories, and is commonly employed by engineers in countries where the metric system is adopted. The *pound-calorie* is similarly employed in connection with the British system of weights, and is equal to 453.6 gramme-calories, if 1 lb. is taken as 453.6 gm.

The term calorie is also employed in stating the total heat or total energy of a substance, such as water, or steam, when measured per unit mass on the Centigrade scale. It is unnecessary in this case to specify the unit of mass because the total heat measured in pound-calories per pound is obviously the same for any given substance and range of temperature as that measured in gramme-calories per gramme, provided that the same unit of mass is employed in either case in measuring the substance and in defining the heat unit. In this connection the *mean calorie*

is most commonly employed, defined as one hundredth part of the increase of total heat of water per unit mass between  $0^{\circ}$  and  $100^{\circ}\text{C.}$  under atmospheric pressure.

Similar units of heat may be defined in terms of the Fahrenheit and Réaumur scales of temperature, but are rarely, if ever, called by the name calorie, or employed for purely scientific purposes. By far the most important of these is the *British Thermal Unit* (B.Th.U.), defined as the quantity of heat required to raise one pound of water one degree on the Fahrenheit scale. One B.Th.U. is equal to  $453.6/1.8$  or 252 gramme-calories precisely.

The absolute values of all the above units of heat depend on the properties of water in a manner which is explained in the article CALORIMETRY. Their relations to other units are further illustrated in the article HEAT.

**CALORIFIC VALUE**, the number of heat units obtained by the complete combustion (*q.v.*) of unit mass of a fuel (*see* FUEL).

**CALORIMETRY**, is the scientific term for the measurement of quantities of heat and must be carefully distinguished from thermometry, which signifies the measurement of temperature or degree of hotness. Quantities of heat may be measured in various ways by observing the effects they produce. The most important of these effects for the present purpose are (a) rise of temperature, (b) a change of state, (c) transformation of electrical or mechanical energy into heat, or vice versa. The object of the present article is to illustrate the various methods of measurement by reference to historical experiments, to discuss the assumptions made and the experimental difficulties involved in their application, and to compare the results with special reference to the mechanical equivalent of heat, and to the order of accuracy attainable.

The fundamental assumption made in measuring quantities of heat by any method is that the quantity of heat contained in any body in a given state at a definite temperature and pressure must always be the same under the same conditions at any time, no matter what changes the body may have undergone in the interval, provided that it has been restored to its original state. This was assumed by all observers from the earliest times, but was first put in categorical form by Carnot (*see* HEAT) as the basis of his argument on the motive power of heat by the method of the cycle. It was also assumed as self-evident that the total heat per unit mass of any substance, such as water, in a homogeneous state, must be the same for different portions of the substance when thoroughly mixed to a uniform temperature and pressure. In other words that the heat-content of any body of uniform composition must be simply proportional to its mass, other things being equal. Since it was manifestly impossible to deprive any body completely of heat, the absolute value of the total heat contents could not be measured in any case; but it sufficed for practical purposes to be able to measure the change of total heat between any limits, from which the total heat of any substance per unit mass, reckoned from a convenient zero such as  $0^{\circ}\text{C.}$ , could be inferred for any temperature. But with the rough apparatus employed by the early experimentalists, it appeared that the increase of total heat was so nearly proportional to the rise of temperature within the limits of error of their measurements that it sufficed to tabulate for each substance a single specific constant  $S$ , called the "specific heat," representing the rate of increase of the total heat with temperature. Taking water as the standard substance of specific heat unity, the unit of heat on this system is the quantity required to raise unit mass of water  $1^{\circ}$  in temperature. In terms of this unit the specific heat  $s$  of any other substance may be defined as the quantity required to raise unit mass of the substance  $1^{\circ}$  in temperature. It follows that a body of mass  $m$ , composed of a substance of specific heat  $s$ , will require per degree rise of temperature a quantity of heat represented by the product  $ms$ , which is called the "thermal capacity" of the body considered. These approximate definitions, tacitly assuming the constancy of the specific heat, will suffice for the immediate purpose as a basis of discussion of experimental methods of measurement in illustration of the various points in which further

precision of statement or manipulation is required in accurate calorimetry.

**Method of Mixtures.**—The method originally employed in nearly all cases was the familiar method of mixtures as described in textbooks. The apparatus in its simplest form consists of an open vessel, of known thermal capacity, containing a known mass of water at atmospheric temperature  $t_0$ , and provided with a thermometer and a stirrer. A known mass  $m$  of the substance to be tested is heated to a suitable temperature  $t_1$  in a separate heater, and is then quickly immersed in the calorimeter. The water is well stirred, and its final temperature  $t_2$  is noted as soon as equilibrium has been reached. The loss of heat of the hot substance in cooling from its initial temperature  $t_1$  to the final temperature  $t_2$  is represented by the product of its thermal capacity  $ms$  by the drop of temperature  $(t_1 - t_2)$ . This is equated to the gain of heat by the calorimeter and the contained water due to the rise of temperature  $(t_2 - t_0)$ , which is represented by the product  $M(t_2 - t_0)$ , where  $M$  includes, in addition to the actual mass of the water, a small correction, called the "water-equivalent," representing a mass of water equivalent in thermal capacity to the calorimeter, thermometer and stirrer. The value of  $s$  is thus obtained in the form,  $s = M(t_2 - t_0)/(t_1 - t_2)m$ , and represents the mean specific heat of the substance tested over the range  $t_1$  to  $t_2$  expressed in terms of that of water over the range  $t_0$  to  $t_2$ . If specific heats were all constant, as originally assumed, the mean specific heat over any range would be the same as the actual specific heat at any point. But since we know that the specific heat of any substance may often vary considerably with temperature, it is usually necessary to specify the range of temperature over which the measurement is made. Further, since the scales of different thermometers differ quite appreciably, it is desirable in accurate work to reduce the results to the absolute scale of temperature for the sake of uniformity. It will easily be seen that, unless the specific heat is nearly constant, the familiar method of expression in terms of specific heat becomes rather complicated and difficult to apply. Thus in dealing with cases in which the specific heat is variable, it is usually preferable to express the observations of mean specific heats over large ranges directly in terms of the total heat  $h$ , which greatly simplifies the necessary reduction and tabulation of the results. The total heat per unit mass at any temperature is a definite physical property of the substance, and is that most often required in practical calculations. The quantity actually measured in an experiment like the above is the drop of total heat,  $h_1 - h_2$ , which is equal to

FIG. 1.—CONTINUOUS ELECTRIC CALORIMETER FOR OBSERVING THE VARIATION OF THE SPECIFIC HEAT OF WATER

$s(t_1 - t_2)$ , where  $s$  is the mean specific heat over the same range of temperature. Further examples of this method of expression are given in the later sections of this article.

One of the chief sources of uncertainty in all calorimetric experiments is that heat cannot be perfectly insulated or prevented from escaping. Thus in the simple experiment above described, some heat is lost while the heated body is being transferred to the calorimeter, some heat is lost from the calorimeter as soon as its temperature is raised above that of its surroundings, and some is usually lost by evaporation from the exposed surface of the water. The degree of accuracy attainable in the measurements depends to a great extent on the possibility of preventing

all such losses as are avoidable, and of estimating those which cannot be eliminated. Various methods of effecting this desirable result are described and compared with special reference to the problem of determining the variation of the specific heat of water, which is one of the most fundamental questions in calorimetry, and affords many good illustrations of the difficulties to be encountered in accurate work.

**Variation of the Specific Heat of Water.**—It would appear at first sight to be a simple matter to test the constancy of the specific heat of water by mixing equal weights of water at different temperatures and observing whether the final temperature of the mixture was the mean of the two initial temperatures. In reality the result of any such experiment would depend quite as much on the scale of the thermometers employed, and on uncertainties of heat-loss, as on the actual variation of the specific heat. M. V. Regnault, who made so many advances in calorimetry and thermometry, appears to have come to the conclusion by making some tests of this nature that the variation of the specific heat, at temperatures such as are used in calorimetry, was too small to be detected with certainty. He also made some very elaborate measurements on a large scale with water from a boiler under steam-pressure, over the range from 110° to 190°C., which showed that the total heat  $h$  of water increased somewhat more rapidly at higher temperatures and pressures in a manner which could be represented within the limits of error of his experiments by the simple formula,

$$h = t + 0.2(t/100)^2 + 0.3(t/100)^3 \quad (1)$$

The corresponding value of the specific heat  $s$  at any temperature  $t$  was deduced by differentiation, thus,

$$s = dh/dt = 1 + 0.004(t/100) + 0.009(t/100)^2 \quad (2)$$

These formulae were accepted for more than 50 years as the basis of calculation in steam-engine practice, for which they afforded ample accuracy. They implied a gradual increase of specific heat, starting from the value 1 at 0°C. and reaching 1.00116 at 20°, 1.00425 at 50°C., and 1.0130 at 100°C., thus confirming the conclusion that the variation of the specific heat at ordinary atmospheric temperatures was too small to be worth taking into account in calorimetric experiments, the accuracy of which under the best conditions rarely exceeded 2 or 3 parts in 1,000.

Many able experimentalists who succeeded Regnault found much larger rates of increase of the specific heat at ordinary temperatures. Many of their methods were highly ingenious, but their results were so discordant as to leave little doubt that the remarkable discrepancies between different observers were due mainly to lack of appreciation of the difficulty of the problem. The first reliable indication of the true mode of variation between 0° and 40°C. was that obtained by H. A. Rowland (*see below*) in his experiments on the mechanical equivalent of heat. His observations led to the totally unexpected result that the specific heat of water, instead of increasing steadily with rise of temperature from the freezing point, showed at first a fall of more than 1%, reaching a minimum at 30°, after which a slight increase was indicated. But owing to the rapid increase of the heat-loss at higher temperatures the observations were not continued beyond 35°C. Rowland himself was doubtful on this account about the exact position of the minimum, and considered that the specific heat might go on decreasing as far as 40°. The fact of the diminution of the specific heat in this region was soon verified by many independent observers, though they differed somewhat in the rate of diminution and in the position of the minimum. But they differed so widely at higher temperatures that they did not throw any light on the relation between the thermal unit at 20°C., as employed in the method of mixtures, and the mean thermal unit from 0° to 100°C., as commonly adopted by engineers and used in ice-calorimetry.

The first investigation covering the whole range 0° to 100°, in which due attention was paid to the thermometric difficulties, was that made by Lüdén (Zürich, 1895) under the direction of Prof. Pernet, employing the method of mixtures with mercury thermometers of the Paris type. The results were probably as good as could be obtained by the method employed, which is not

very suitable for the purpose, since the highest observation with the hot water at 97° does not give the *actual* specific heat at 97°, but only the *mean* specific heat from 97° to 18°, the final temperature of the calorimeter. The quantities of hot water added were adjusted to give nearly the same rise of temperature, 11° to 18°, in the calorimeter in each case, so that the mean specific heat of the hot water over each range could be compared with the same standard. The observations of the mean specific heat, six of which were taken for each of ten ranges, seldom differed by more than 2 or 3 parts in 1,000 from the mean at each point, but may have been liable to systematic errors due to evaporation or similar causes. The deduction of the formula for the actual specific heat from the observed values of the mean specific heat over different ranges is a somewhat indirect process which greatly increases the uncertainty of the values of the actual specific heat in the region near 100°C. Lüdén's formula for the actual specific heat  $s$  at any temperature  $t$  between 0° and 100°C. is often quoted, and is as follows:—

$$s = 1 - 0.07668(t/100) + 0.196(t/100)^2 - 0.116(t/100)^3 \quad (3)$$

$\pm 0.00025 \qquad \pm 0.040 \qquad \pm 0.030$

The probable errors of the coefficients, as calculated by Lüdén, are given in the line below the formula itself. The curve represented by this formula is shown by the line marked "Lüdén's formula" in fig. 2. It shows a minimum at 25°C. followed by a rapid rise to a maximum at 87°, and falls rapidly beyond 100° instead of rising continuously like Regnault's curve given by formula (2). But a formula of this type, in which the coefficients are large and of opposite signs, cannot be trusted for extrapolation.

**Method of Electric Heating.**—The method of electric heating, which is now commonly applied for measuring specific heats at high or low temperatures, offers special advantages for the variation of the specific heat. After the substance to be tested has been heated or cooled to any desired temperature in a suitable thermostat, a measured quantity of heat is imparted to it by an electric heating coil, sufficient to produce a small rise of temperature, which is carefully measured. The actual specific heat is thus obtained over a small range at the desired point, in place of the mean specific heat over a large range of temperature. The method has the additional advantage that the heat-loss in transference, which is such an uncertain element in the method of mixtures, may be entirely avoided, since the substance is heated after being placed in position in the calorimeter.

The arrangement shown in fig. 1 was employed by H. L. Callendar and H. T. Barnes (*Phil. Trans.* 1902) in applying the electric

FROM "PHILOSOPHICAL TRANSACTIONS," BY COURTESY OF THE ROYAL SOCIETY

FIG. 2.—CURVES REPRESENTING FORMULAE (3), (6) AND (8). Variation of specific heat of water, between 0° and 100°C, in terms of calories at 20°C, as in Table I.

method to the variation of the specific heat of water. A steady current of water flowing through a fine tube from B to A is heated during its passage by a steady electric current through a central conductor of suitable resistance. The current produces a steady difference of temperature between A and B, which is measured by a single reading with a differential pair of platinum thermometers (*see THERMOMETRY*). The flow-tube and the thermometer pockets at either end are protected from heat-loss by enclosure in a silvered vacuum jacket, which is surrounded by an external water jacket maintained at the desired temperature

by a vigorous circulation of water from a delicate thermostat. The adoption of a steady-flow method eliminates all the discontinuities of operation which are so troublesome in the method of mixtures. After turning on the electric current and allowing sufficient time for the temperature to become perfectly constant in the outflow pocket A, the water current through AB is switched over into a weighing flask (not shown in the figure) without altering any of the conditions, and is collected for a suitable interval of time, recorded on an electric chronograph, in order to deduce the flow  $m$  in gm. per second. Meanwhile one observer records the difference of temperature  $dt$  between A and B, which remains practically constant, while another records the difference of potential  $E$  between the ends of the central heater and the current  $C$  passing through it by means of a potentiometer. The water-equivalent of the calorimeter, consisting mainly of the outflow pocket A, is very small, and is not required at all in the calculation if the temperature is constant. Sufficient stirring is effected by causing the water to circulate spirally round the bulbs of the thermometers and round the central heater in the flow tube AB. The heat generated by the stirring can be measured by observing the difference of pressure between A and B, but never exceeds 1 in 10,000 of the heat supplied electrically. The temperature of the external water jacket, which is always nearly the same as that of the inflow pocket B and of the thermostat, is not required with great accuracy, and is read by the mercury thermometer shown in the figure. The use of a differential pair of platinum thermometers for measuring the rise of temperature  $dt$  of the water in passing through the fine flow tube (which is required with the greatest accuracy) ensures that the observation shall be simultaneous for both thermometers, and avoids the uncertain corrections for change of zero and for stem-exposure to which even the best mercury thermometers are liable.

The steady-flow method possesses the advantage that the external loss of heat is greatly reduced and is rendered more regular, so that it becomes easier to measure with certainty. There is no free surface of water to permit loss by evaporation as in an open calorimeter. The vacuum jacket eliminates the possibility of loss by convection or by deposition and evaporation of dew, which are common sources of trouble in calorimetric experiments by other methods, but it cannot entirely eliminate losses by conduction or radiation. The direct determination of these residual losses, by experiment at each observation, is readily effected by the following method.

The rate of heat supply by the electric current in watts is given by the product  $EC$ , and is equal to the rate at which heat is being carried off by the water together with the rate of heat loss by conduction and radiation; these may be expressed in watts and represented by the products  $Jsm\,dt$  and  $h\,dt$ , respectively, since both are proportional to the rise of temperature  $dt$ . We thus obtain the general equation of the method,

$$EC = Jsm\,dt + h\,dt \quad (4)$$

in which  $J_s$  is the variable specific heat to be determined in joules or watt-seconds per gram per degree rise of temperature,  $m$  is the flow of water in grams per second, and  $h$  is the rate of heat-loss in watts per degree rise. A second observation is then taken at the same temperature with a different value of the water flow  $m$ , and the current  $C$  is adjusted to give the same rise of temperature. We thus obtain a second equation in which the term  $h\,dt$  is the same as in (4) and can be eliminated by subtraction. The required value of  $J_s$  is thus obtained in the form,

$$J_s = (E'C' - E''C'') / (m' - m'') \, dt, \quad (5)$$

where the quantities observed in the two separate flows are distinguished by dashes. In practice it is seldom possible to get the rise of temperature precisely the same in both observations, and the other theoretical conditions cannot be satisfied exactly, but it is easy to allow for any small deviations of this kind by making slight modifications in the calculation.

The results obtained by this method over the whole range  $0^\circ$  to  $100^\circ\text{C.}$  can be represented satisfactorily by the following formula:—

$$s = 0.98536 + 0.504/(t+20) + 0.0084(t/100) + 0.009(t/100)^2 \quad (6)$$

in which the value of the constant 0.98536 is adjusted to make  $s = 1$  when  $t = 20^\circ$ , or the specific heat is expressed in terms of a unit at  $20^\circ\text{C.}$  The other terms are small and positive, and can be calculated with ample accuracy for all possible purposes by means of a 10-in. slide rule. The corresponding curve is shown by the line marked "Callendar's formula" in fig. 2. Some of the

FIG. 3.—BUNSEN ICE CALORIMETER. ENCLOSED IN VACUUM JACKET TO PREVENT CREEP OF ZERO

separate observations, taken with six different calorimeters, are plotted in the figure in order to indicate the order of agreement obtained. Lüdén's observations could not be plotted in the same way, since they did not represent the actual specific heat at any point but only the mean specific heat over considerable ranges. Formula (6) shows a minimum at  $37.5^\circ\text{C.}$ , and differs from Lüdén's by about 1% between  $70^\circ$  and  $90^\circ\text{C.}$ , but shows no sign of a maximum, and continues to rise at a rate very similar to Regnault's formula (2), with which it agrees closely at  $200^\circ\text{C.}$  It is not intended for extrapolation above  $100^\circ\text{C.}$  as it represents the specific heat at a constant pressure of 1 atmosphere, which cannot be directly measured at temperatures above the boiling-point.

The figures in the column headed "Specific Heat" show the variation given by formula (6). It will be seen that the specific heat at  $15^\circ$  exceeds that at  $20^\circ$  by little more than 1 in 1,000, which is beyond the limits of error of ordinary calorimetric experiments. The figures in the next column give the corresponding values of the total heat  $h$  obtained by integrating the same formula for the specific heat. The mean thermal unit over the range  $0^\circ$  to  $100^\circ$  is obtained by dividing the value of  $h$  at  $100^\circ$  by 100, and is seen to be 1.0016 times the specific heat at  $20^\circ$ . The mean specific heat over any range is most easily obtained from this column by dividing the drop of total heat by the corresponding drop of temperature. But for most experiments in which large ranges of temperature are used in the calorimeter the converse process is required, namely, to deduce the drop of total heat  $h' - h''$  from the observed drop of temperature  $t' - t''$ . This is most easily done by adding the small difference  $h' - t'$ , and subtracting  $h'' - t''$ , which may be obtained from the table by inspection.

In comparing results obtained by different methods it is always desirable to go back to the quantities actually measured, whenever

possible. Rowland in his experiments observed the increase of total heat from  $5^{\circ}$  to  $35^{\circ}$  in mechanical units, which are reduced to thermal units in the column headed "Rowland" by dividing by his value of the mechanical equivalent at  $20^{\circ}$ . His results thus reduced are seen to agree very closely with those found by the electric method over the same range, although the values of the specific heat for successive intervals of  $5^{\circ}$  (which are generally taken as the basis of comparison) are somewhat irregular owing to the increasing uncertainty of the heat-loss towards the latter part of the range. Similarly in Lüdén's experiments, the quantity measured was not the specific heat at  $t$ , but the drop of total heat of the hot water (or the gain of total heat of the cold water) introduced into the calorimeter. His values of the total heat agree as closely as could be expected with the continuous electric method from  $0^{\circ}$  to  $40^{\circ}$ . Beyond  $40^{\circ}$  they show an increasing divergence, which amounts, however, to only 0.2% at  $70^{\circ}$ , where his curve of specific heat shows a discrepancy of nearly 1%.

Lüdén's curve of specific heat was reproduced with remarkable fidelity by W. R. and W. E. Bousfield (*Phil. Trans.* 1911), who employed a most ingenious method of electric heating in a Dewar-flask calorimeter. They measured the rise of temperature with mercury thermometers, and were unable to extend the observations beyond  $80^{\circ}$  on account of evaporation from the surface of the water. When expressed in terms of total heat, the discrepancies of their results from formula (6) are somewhat smaller than those of Lüdén's formula, and may probably be attributed to uncertainties of heat-loss by evaporation, etc., at the upper limit of their range, or to errors due to stem-exposure and variations of zero such as are inevitable with mercury thermometers, or possibly to the difficulty of determining the water-equivalent of the calorimeter and heater satisfactorily. In any case the type of variation shown by Lüdén's curve for the specific heat, with a maximum below  $100^{\circ}$  followed by a rapid fall at higher temperatures, is quite inadmissible on theoretical grounds, besides being in contradiction with the results of experiments at higher temperatures, all of which appear to require a continuous increase of the specific heat with rise of temperature.

**Theoretical Explanation of the Variation.**—Rowland suggested that the increase of the specific heat of water on approaching the freezing-point should be due to an increasing proportion of molecules of ice in the liquid. Assuming that each ice molecule in melting absorbs a quantity of heat equivalent to its latent heat of fusion, the proportion of ice molecules in water at the freezing-point would be something in the order of 1% of the mass. Nearly all of these would be melted by the time the water reached a temperature of  $40^{\circ}$ , where the specific heat has already begun to increase again. H. T. Barnes has succeeded in measuring the specific heat of supercooled water below the freezing point, and finds that it continues to increase as the temperature falls, following a prolongation of the same curve as that found above the freezing point. The high specific heat of water has often been attributed to the complexity of the water molecule, which has been the subject of much speculation; but it is futile to speculate until something definite is known of the nature of the polymers present and the laws of equilibrium between them. There is no doubt that the formation and dissociation of complex molecules must profoundly affect the specific heat.

In the case of the vapour, on the other hand, there is little doubt that the great majority of the molecules of steam are single molecules of the type  $H_2O$ . (See VAPORIZATION.) It appears highly probable that a certain proportion of steam molecules must also exist in solution in the liquid when in equilibrium with the vapour in the state of saturation, and that these molecules are chiefly responsible for the increase of specific heat of the liquid. According to the vapour-pressure theory of osmotic pressure (see THERMODYNAMICS) the surface of any liquid acts as a semi-permeable membrane, which allows free passage to the vapour-molecules. This implies that the density of the vapour molecules in the liquid should be the same as that of the vapour with which it is in equilibrium, or that water at any temperature should contain its own volume  $v$  per unit mass of saturated steam at the same temperature. Since a volume  $v$  of steam already

exists in the water in the state of vapour, the vaporization of unit mass of water with increase of volume from  $v$  to  $V$  (the corresponding volume of steam) involves the vaporization of a volume  $V-v$  of steam. Thus the whole latent heat  $L$  of vaporization per unit mass corresponds with the generation of a volume  $V-v$  of steam, and the latent heat of the volume  $v$  already contained in the water should add the fraction  $v/(V-v)$  of  $L$  to the total heat

FROM "WORLD POWER"

FIG. 4.—SECTIONAL DIAGRAM OF JACKETED CONDENSER, FOR MEASURING TOTAL HEAT OF STEAM AT HIGH PRESSURE

$h$  of the water. According to this view, the effect of the steam molecules on the variation of the total heat  $h$  of the liquid, reckoned from  $0^{\circ}C$ ., may be represented by the simple formula:

$$h = s_0 t + vL/(V-v) \quad (7)$$

A formula of this type, though without any theoretical interpretation, was first proposed by Paul de St. Robert (Turin, 1857), as representing Regnault's results between  $100^{\circ}$  and  $200^{\circ}C$ . just as well as formula (1). It was also pointed out by J. MacFarlane Gray (*Proc. Inst. C.E.* 1902) that, by superposing on formula (7) the effect of the ice molecules near the freezing point, a curve very similar to that found by the continuous electric method for the variation of the specific heat between  $0^{\circ}$  and  $100^{\circ}C$ . would be obtained. Since the effect of the ice molecules becomes evanescent above  $40^{\circ}C$ ., the simple formula (7) was adopted as the basis of Callender's steam tables (*Ency. Brit.* 1902), though formula (6), including the effect of the ice molecules, is still required for calorimetric experiments between  $0^{\circ}$  and  $40^{\circ}$ .

TABLE II.

Total heat  $h$  of water under saturation pressure. In terms of mean thermal unit  $0^{\circ}$  to  $100^{\circ}C$ .

| Temperature<br>C. | Regnault<br>(1) | Dieterici<br>(8) | (8) + $apv$ | Formula (7) |
|-------------------|-----------------|------------------|-------------|-------------|
| $150^{\circ}$     | 150.7           | 150.92           | 151.16      | 150.91      |
| $200^{\circ}$     | 202.2           | 203.11           | 203.54      | 203.55      |
| $250^{\circ}$     | 254.7           | 257.16           | 258.36      | 259.78      |
| $300^{\circ}$     | 308.3           | 313.46           | 316.41      | 322.86      |
| $350^{\circ}$     | 363.6           | 374.98           | 382.03      | 401.12      |
| $374^{\circ}$     | 390.5           | 401.91           | 418.91      | 481.25      |

The first column gives the temperature. The column headed Regnault (1) gives values of  $h$  by formula (1) reduced in the proportion 100/100.5, since the value of  $h$  at  $100^{\circ}C$ . is 100 in terms of the mean thermal unit, whereas Regnault's formula (1) gives  $h=100.5$  at  $100^{\circ}C$ . in terms of a unit at  $0^{\circ}C$ . In the case of Dieterici's formula (8) (see below) the values are already expressed in terms of the mean thermal unit. His formula for  $h$  is very similar to Regnault's but with different coefficients. Both are liable to the objection that they do not make the total heat increase sufficiently fast to satisfy the theoretical conditions at the critical point,  $374^{\circ}C$ . The values of the thermodynamic formula (7) are expressed in terms of the mean thermal unit by choosing the value of the constant  $s_0$  to be 0.99666, which is very nearly the same as the minimum value of the specific heat 0.99697 given by formula (6) in terms of the mean thermal unit.

**Method of Fusion.**—The measurement of quantities of heat in terms of change of state, e.g., fusion of ice or condensation of steam at constant temperature, is theoretically the most perfect in that no question of the thermometric scale is directly involved. The practical difficulties encountered by Black and other observers

(see HEAT) in applying the method of fusion lay in the measurement of the quantity of ice melted. These troubles were first successfully overcome by R. Bunsen (*Phil. Mag.* 1871), who constructed an apparatus in which the diminution of volume due to the melting of the ice could be observed. The construction of a modern calorimeter of this type is illustrated in fig. 3. The central tube A serving for the reception of the heated body is surrounded by a bulb B filled with air-free water, which communicates at its lower end with a tube C of small bore containing mercury, by which any changes of volume of the water in freezing or melting can be observed with considerable accuracy. The vacuum jacket J surrounding the bulb B was not included in Bunsen's original design but is a later addition intended to eliminate creep of zero, as explained below. In using the instrument, the first operation is to freeze some of the water in B by circulating a freezing liquid, such as alcohol or ether at a low temperature, through the inner tube A, which thus becomes coated with a sheath of ice. The whole apparatus is then immersed in a bath of melting ice, leaving only the upper end of A and the tube C exposed. If a hot body is now dropped into the tube A, the quantity of heat which it gives up in cooling to  $0^{\circ}\text{C}.$  will melt a corresponding amount of the ice sheath. The quantity of ice melted is shown by the retreat of the mercury along the tube C, or preferably by observing the weight of mercury sucked into the tube as in using a weight thermometer. Since the weight thus observed is directly proportional to the quantity of heat added, and is independent of the dimensions of the calorimeter, the constant factor for reducing weight of mercury drawn in to gram-calories of heat added is the same for all ice-calorimeters of this type. The constant is usually determined by adding known quantities of heat in the form of water at its boiling-point. Dieterici (*Ann. Phys.* 1905) used the method for observing the variation of the mean specific heat of water at temperatures up to  $300^{\circ}\text{C}.$ , by sealing known weights of water in quartz-glass bulbs which were heated to various temperatures and dropped into an ice-calorimeter. By using thin bulbs heated to  $100^{\circ}\text{C}.$  he was thus able to determine the constant of the ice-calorimeter in terms of the mean thermal unit with an accuracy not previously achieved. The value found was 15.492 mg. of mercury per mean gram-calorie centigrade, in place of the value 15.44 previously employed as the mean of the results of other workers. Dieterici's value of this important constant has since been confirmed by E. Griffiths (*Proc. Phys. Soc.* 1913), who found 15.491 mg. of mercury as the equivalent of the mean gm. calorie of 4.185 joules, as given by the electric method shown in fig. 1.

The chief advantage of the ice calorimeter is that it is very perfectly protected against external loss of heat provided that the internal ice sheath is sufficiently continuous to prevent any heat escaping directly from the heated body to the external ice bath, and that the temperature of the ice bath is precisely the same as that of the ice sheath inside the calorimeter. Sometimes there may be a slight difference in quality of the ice, causing a gradual creep of zero when the calorimeter is directly immersed in the ice bath. This creep of zero, which is often troublesome in delicate experiments, may be completely eliminated, as has been explained by H. L. Callendar (*Ency. Brit.* 1902), by enclosing the bulb of the calorimeter in a vacuum jacket, as indicated in fig. 3, which reduces any possible interchange of heat about 1,000 times as compared with direct immersion of the calorimeter in the ice bath. The method is then very convenient for measuring small quantities of heat, such as those due to the Peltier effect (see also ELECTRICITY), especially when the heat is generated inside the calorimeter. The risk of heat-loss in transference cannot be avoided, any more than in the method of mixtures, if the heated body has to be dropped into the calorimeter, though the uncertainty may be reduced by skillful manipulation.

The most important correction in Dieterici's experiments on water was that for the thermal capacity of the quartz bulbs, which amounted to about a quarter of that of the contained water in the experiments at  $100^{\circ}$  to  $130^{\circ}\text{C}.$ , and was calculated from a formula for the specific heat of quartz-glass. He estimated the order of accuracy of the experiments at  $100^{\circ}\text{C}.$  as 1 in 1,000 on the

mean specific heat, but stated that the precision attainable diminished at lower temperatures as the quantity of heat to be measured was reduced. For this reason the method was not suited for giving accurate results for the variation of the specific heat near the freezing point. The correction for the water equivalent of the quartz bulbs became more important at higher temperatures, where it was necessary to use much thicker bulbs in order to with-

FIG. 5.—JOULE'S APPARATUS FOR THE DETERMINATION OF THE MECHANICAL EQUIVALENT OF HEAT, 1878. JOULE'S ORIGINAL APPARATUS OF 1850 DIFFERED IN MANY RESPECTS

stand the steam pressure. From  $150^{\circ}$  to  $220^{\circ}$ , bulbs having a thermal capacity about equal to the contained water were employed. Above this point up to  $300^{\circ}$ , the limit of the experiments, the bulbs had a capacity nearly 4 times that of the water, which would greatly increase the uncertainty of the results. Another small correction was applied for the internal latent heat of the steam generated in the space left vacant above the water level, since the bulbs could not be completely filled without risk of bursting under the enormous pressures which might be generated by the expansion of the water. When these corrections are applied the quantity measured, as Dieterici points out, is the drop of internal energy of the water in cooling to  $0^{\circ}\text{C}.$  from its initial temperature, since the water is enclosed in a practically non-expansive envelope, and no external work is done either in heating or cooling. Thus the formula given by Dieterici for the mean specific heat  $s_0, t$  from  $0^{\circ}$  to  $t$ , namely

$$s_0, t = 0.99827 - 0.005184(t/100) + 0.006912(t/100)^2 \quad (8)$$

when multiplied by  $t$ , represents the internal energy of water at  $t$  under saturation pressure, reckoned from  $0^{\circ}\text{C}.$  and expressed in terms of the mean thermal unit, giving  $s_0, t = 1$  when  $t = 100$ . This formula gives slightly higher values for the internal energy than Regnault's formula (1) for  $h$ , as shown in Table II., and has commonly been adopted for the total heat of water by Continental and American writers on the subject. But in order to deduce the total heat  $h$  from the internal energy, the quantity  $apv$  should be added, representing the thermal equivalent of the work required to pump a volume  $v$  into a boiler against the steam-pressure  $p$ . This correction is indicated in the next column of Table II. and gives higher values than (8), agreeing very well with the thermodynamic formula (7) up to  $200^{\circ}\text{C}.$ , but still falling short of the rapid increase shown by (7) near the critical point. The corresponding formula for the specific heat  $s$  at  $t$ , as obtained from (8) by differentiation, and expressed in terms of a unit at  $20^{\circ}\text{C}.$ , is represented by the curve marked "Dieterici" in fig. 2. As Dieterici remarks, the formula for  $s$  has an inferior degree of accuracy to that representing the mean specific heat,  $s_0, t$  since it does not so directly represent the results of observation. Some additional uncertainty in the reduction arises from the value of the unit at  $20^{\circ}$ , which Dieterici gives as 0.9974 in terms of the mean unit, in place of the value 0.9984 given by the continuous electric method. The agreement of these two values to 1 in 1,000 coincides with Dieterici's estimate of the limit of accuracy of the ice calorimeter.

**Method of Condensation.**—The Steam Calorimeter, in which quantities of heat are measured in terms of the latent heat of condensation of steam, has been applied with success by J. Joly (*Proc. R.S.* 1889) to the difficult problem of measuring the specific heats of gases at constant volume, and is undoubtedly capable of giving very accurate results under suitable conditions. But its use for accurate work is practically restricted to the range from atmospheric temperature to  $100^{\circ}\text{C}$ ., and it is of less general applicability than the ice calorimeter. The method also requires very delicate weighing of the quantity of steam condensed, as 1 gm. calorie corresponds to the condensation of less than 2 mg. of steam. Assuming Regnault's value 536.68 for the latent heat of steam at  $100^{\circ}\text{C}$ ., Joly found, by weighing the steam condensed in heating a known mass of water from  $12^{\circ}$  to  $100^{\circ}\text{C}$ ., that the mean specific heat of water between these limits was only 0.9952, whereas the value given by Regnault's formula was 1.0053, and that given by Lüdin's formula 1.0086, exceeding the value found by Joly by more than 1%. Joly's observation was of special interest at the time (1895) as the first suggestion that the accepted values of the total heat of water at  $100^{\circ}$  and the latent heat of steam were discordant by an amount which could hardly be neglected in the case of such important constants. Joly's observation was probably very accurate but gave only the ratio of the two, and not the actual value of either. The truth probably lay between the two extremes, as was subsequently found to be the case. Thus if we take the values of the total heat of water at  $12^{\circ}$  and  $100^{\circ}$ , as deduced from formula (6) and given in Table I., we find the mean specific heat 1.00104 in terms of a unit at  $20^{\circ}\text{C}$ . and deduce for the latent heat from Joly's observation the value 540.0 in place of Regnault's 536.7. The higher value, 540 in terms of a unit at  $20^{\circ}\text{C}$ ., has since been confirmed by other observers, though it may still be a little too low on account of the difficulty of eliminating the last traces of moisture in saturated steam or any other vapour. For this reason it is usually preferable, in finding the total heat, or the latent heat, of a saturated vapour, to observe the total heat at the required temperature  $t$ , but at pressures slightly below that of saturation to make sure that the vapour is dry. Values for the dry saturated vapour may then be deduced by extrapolating the isothermal curves thus obtained on the  $PT$  diagram to the saturation pressure.

**Steady Flow Methods.**—In place of measuring the rise of temperature in a fixed mass of water, as in the method of mixtures, it is often preferable, in cases where the heat to be measured can be supplied at a steady rate, to keep the temperature in every part of the apparatus constant by removing the heat as fast as it is generated by means of a steady flow of cooling water. When the conditions have become stationary the rate of heat supply can be measured by observing the rate of flow and the rise of temperature of the cooling water. The method is especially suitable for measurements of the total heat of liquids or vapours, and of the calorific values of gaseous and liquid fuels, which include many of the most important cases in practice. It has the advantage that the water equivalent of the apparatus is not required, which greatly facilitates work at higher temperatures and pressures, where the thermal capacity of the apparatus is often large and its accurate determination would be a matter of considerable difficulty. A steady flow method combined with electric heating has already been illustrated in fig. 1. The object in that case was to determine the variation of the specific heat of the steady current of water. The total heat of other fluids in steady flow may then be measured by using a steady flow of water to carry off the heat. In this case there are two flows to be measured, but the complication of electric heating is no longer required. As a good illustration of the way in which difficulties of measurement may be circumvented by the employment of a steady flow method, we may take the measurement of the total heat of steam at high temperatures and pressures, which is a problem of some practical interest and importance, but has hitherto resisted solution by any of the older methods.

The heart of the apparatus, in which the steam is condensed and its drop of total heat measured, is called a jacketed condenser and is shown in section in the annexed fig. 4, omitting such details of

construction as are not essential to the principle of the method. The auxiliary apparatus required for generating a steady flow of steam consists of a feed-pump, designed to work up to a pressure of 4,000 lb. per sq. in., delivering water at the desired pressure to an electric boiler and superheater capable of generating steam and heating it up to the desired temperature. The steam then passes through a thermometer pocket in which its initial temperature and pressure are accurately observed, defining the state in which its total heat  $H_1$  is to be measured. Immediately on leaving this high-pressure pocket, the steam is passed through a throttle tube (which reduces the pressure to atmospheric without altering its total heat) before entering the condenser through the inlet marked A on the left of the figure. The condenser proper consists of the annular space between the two inner tubes, in which the steam is caused to circulate spirally, as indicated in the figure, in order to increase the efficiency of condensation. After being condensed to water at atmospheric pressure the steam leaves the condenser at B and passes through a thermometer pocket, not shown in the figure, in which its final temperature as condensate is observed. Its total heat  $H_2$  in this state is known from the table already given. Finally the condensate is cooled to atmospheric temperature before being collected in the tanks, which are weighed at suitable intervals in order to determine the flow of steam  $M$  in lb./min or gm./sec. or other convenient units.

The steady flow of cooling water by which the steam is condensed is supplied from a large tank in which the level is maintained constant. After passing through a thermometer pocket at C, where its temperature is observed, the cooling water circulates round the jacket shown in the figure, which is separated from the condenser proper by the layer of lagging. It then circulates round the condenser tube, abstracting heat from the steam and rising in temperature, and leaves the apparatus through a thermometer pocket attached to the outlet at D. It is cooled again to atmospheric temperature on its way to the weighing tank, in which the

FIG. 6.—ROWLAND'S APPARATUS FOR THE DETERMINATION OF THE MECHANICAL EQUIVALENT OF HEAT, 1879

flow  $m$  of cooling water is measured for the same intervals as that of the condensate  $M$  by switching over the flows simultaneously into their respective tanks. The function of the jacket, through which the cooling water enters the apparatus, is to catch any heat which might otherwise escape from the hot water surrounding the condenser. In addition to this, the whole apparatus is enclosed in an external jacket, not shown in the figure, supplied with circulating water from the same tank as the cooling water. This external jacket is protected by lagging and, being always at the same temperature as the internal jacket surrounding the con-

denser, serves to prevent any heat reaching the cooling water from outside, after its inflow temperature has been measured at C. With these precautions, the external loss of heat from the condenser is almost incredibly small, rarely exceeding a fifth of 1%, even with a rise of temperature of 80°C. in the cooling water.

The theory of the method is extremely simple and has the advantage of giving the result directly in terms of total heat, without any ambiguity with regard to the quantity measured. The kinetic energy of flow through the pockets being negligible, when everything is steady, the rate at which heat is being carried in by the steam, namely  $MH_1$ , must be equal to the rate at which heat is being carried off by the condensate and the cooling water, namely  $MH_2 + m(h_2 - h_1)$ , together with the rate of heat-loss  $X$  from the high-pressure pocket, and  $x$  from the condenser. Dividing each of these quantities by  $M$ , so as to obtain the total heat  $H_1$ , of the high-pressure steam per unit mass, we find the equation,

$$H_1 = H_2 + (h_2 - h_1)m/M + (X + x)/M \quad (9)$$

It should be observed that  $H_2$  and  $X + x$  are small compared with  $H_1$ , and that the term requiring the greatest accuracy of measurement is  $h_2 - h_1$ , the gain of total heat of the cooling water. This is always very nearly equal to the corresponding rise of temperature, as directly measured with a differential pair of platinum thermometers, from which the gain of total heat is easily deduced by adding and subtracting the small differences shown in Table I. between  $h$  and  $t$ , as previously explained. The rates of heat-loss,  $X$  and  $x$ , can be found, as in the continuous electric method, by varying the flows  $M$  and  $m$  independently in suitable ratios. This is more troublesome than in the electric method, but need not be repeated at every observation if the same apparatus is employed for a considerable period.

It might be thought that it would be necessary to condense the steam under its original pressure in order to measure the total heat. This was the case according to the old definition of the total heat by Regnault, who actually measured the total heat of steam in this way up to 12 atmospheres. Owing to the high pressure, he met with many difficulties from leakage and measured the total heat of water in a different way, which led to awkward discrepancies in the theory. With the new definition of total heat, first proposed by Callendar in a previous edition (*Ency. Brit.* 1902), and now generally accepted, all these difficulties and discrepancies disappear, and the steam may be condensed at any convenient pressure without affecting the results for the total heat. The advantage of condensing always at atmospheric pressure is that only one design of condenser is required. Moreover the best security against any possibility of leakage between the steam and the cooling water is obtained, since the perfect absence of leakage may be tested at any time by employing much higher pressures. Nevertheless it is essential, in order to secure permanent immunity from leakage, to design the condenser in such a way that every tube is perfectly free to expand. Otherwise it would rack itself to pieces in time by differences of expansion between the hot and cold tubes. In practice both the inside and the outside of the annular space are utilized for condensing the steam, by making the cooling water circulate through the whole length of both. But these details of construction could not be shown in the diagram without obscuring the main principle.

It is a great advantage of the method that the same apparatus, without any modification, can be applied for measuring the total heat of water by simply pumping hot water through it. In point of fact it was first designed with the object of verifying the thermodynamic formula (7) for the variation of the total heat of water at high pressures near saturation; but owing to the difficulty of procuring the expensive apparatus required for high pressures it was first applied (*Phil. Trans.* 1912) to the verification of Table I. for the total heat between 0° and 100°C. as deduced from the observation of the specific heat by the continuous electric method. Since the World War, with the assistance of the British Electrical Research Association, who provided the necessary funds, it has been possible to extend the measurements for both steam and water to pressures in some cases exceeding 3,500 lb. There was no difficulty in measuring the total heat  $h$  of water at high pressure

provided that the temperature was 2° or 3° below that of saturation; but, at or near the saturation point, any trace of air in the water caused profuse generation of steam in the air bubbles and tended to give results appreciably higher than equation (7). This difficulty was surmounted by supplying the pump with distilled water from a special apparatus, by which it was freed from air immediately before passing into the pump. This led to so great an improvement that there seems to be little doubt that equation (7) holds up to the critical temperature where the volume of water becomes indeterminate. The actual value of  $h$  at the critical point, as given in Table II., remained uncertain, so long as the corresponding value of the volume  $v$  rested on theoretical assumptions, such as those of van der Waals, which were very doubtful, if not entirely erroneous. But both  $h$  and  $v$  have now been determined by direct experiment at this point, and are found to satisfy formula (7).

**Mechanical Equivalent of Heat.**—The history of the establishment of the mechanical theory of heat is reviewed in the article HEAT, in which a general account is given of the early experiments by Joule and others demonstrating the transformation of other kinds of energy into heat. The phrase "mechanical equivalent" was originally employed to denote the number of gravitational units of mechanical work, such as foot-pounds or kilogram-metres, required to produce one unit of heat when completely converted into heat by friction or otherwise. By a natural process of transition the same phrase is now commonly used for the numerical ratio of equivalence between units of energy in any form and the various units of heat. Since most forms of energy are measured directly or indirectly in terms of mechanical work done against gravity, it is merely a question of conversion of units, when one value of the mechanical equivalent of a particular thermal unit has been found by experiment; to deduce the corresponding result for any other thermal unit in terms of any other unit of energy. Owing to the multiplicity of units both of energy and heat, there are many different values for the mechanical equivalent on this basis; but for scientific purposes it is usual to reduce experimental results to absolute units on the C.G.S. system, taking the joule or watt-second as the absolute unit of energy and the gram-calorie centigrade at 20°C. on the scale of the hydrogen thermometer as the unit of heat. This has the advantage of excluding the effect of local variations of gravity and fits conveniently with the electrical system of units. Engineers, on the other hand, still prefer the gravitational system as fitting better with the practical measurement of pressure in terms of weight per unit area, since the variations of gravity are relatively small and can be taken into account if necessary in special cases.

The experimental measurement of the mechanical equivalent of heat requires the accurate determination of the quantity of heat generated by the expenditure of a known amount of mechanical work, and is mainly a question of calorimetry. The simplest method to use in the laboratory is the electric method, since the measurement of electric energy requires no moving parts in the apparatus, and is very accurate if the absolute values of the electric standards employed are known. Accordingly as soon as the absolute value of the ohm had been determined by the committee of the British Association, the electric method of calorimetry was applied to the verification of Joule's determination of the mechanical equivalent of heat. The result gave a value more than 1% lower than the mechanical method employed by Joule in 1850. As these early experiments had been carried out on a small scale with a very laborious method of measuring the work and applying corrections for heat-loss, Joule consented to repeat them on a much larger scale with a greatly improved method, as shown in fig. 5. The calorimeter  $h$  containing about 12 lb. of water, was supported on a float  $w$  in a vessel of water  $v$ , so as to be in neutral equilibrium, but was kept at rest by a pair of fine strings passing round a horizontal wheel of radius  $r$  on the circumference of the calorimeter, and supporting equal weights  $kk$  by means of frictionless pulleys. During an experiment the paddles inside the calorimeter were rotated by means of the hand-wheels at the top of the apparatus at such a speed as to keep the weights floating steadily, balancing the turning moment due to the friction of the

paddles churning the water. If the sum of the weights is equal to  $W$  the work done against friction in  $n$  revolutions as shown by the counter will be  $2\pi nW$  in mechanical units. The corresponding value of the heat generated is calculated in the usual way from the product of the thermal capacity  $M$  of the calorimeter and its contents, by the observed rise of temperature ( $t'-t''$ ) corrected for heat-loss. The ratio  $J = 2\pi nW/M (t'-t'')$  gives the required value of the mechanical equivalent in terms of the units employed in the measurement.

As the result of this series of experiments Joule found that 772.55 ft. lb. of work in the latitude of Greenwich were required to raise the temperature of 1 lb. of water  $1^\circ$  at  $60^\circ$  on the scale of his mercury thermometers. This agreed very closely with the value 772 under similar conditions obtained in his earlier experiments in 1850, but disagreed with the value obtained by the electric method on the assumption that the B.A. unit of resistance correctly represented the absolute value of the ohm. The discrepancy was subsequently explained by the discovery that the absolute value of the B.A. unit of resistance was about 1.3% too small as compared with the true ohm.

About the same time H. A. Rowland (*Proc. Amer. Acad.* xv. p. 75, 1880) repeated the measurement of the mechanical equivalent, employing the same method as Joule in 1878, but with many improvements in detail, as illustrated in fig. 6. His calorimeter was suspended by a steel wire, the torsion of which made the equilibrium stable, and was slightly larger and more compact than Joule's. To reduce the relative importance of the heat-loss, he found it necessary to secure a greater rate of heat-supply, about 17 times that employed by Joule. The paddles were mounted on a vertical spindle  $F$ , passing through a gland in the bottom of the calorimeter, and were driven through bevel gearing  $g$  by a belt from a petroleum motor running at a nearly constant speed. The greater part of the torque due to the friction of the paddles inside the calorimeter was balanced by the floating weights  $O$  and  $P$ , suspended by silk ribbons passing over pulleys and round the wheel  $kl$ . The small variations of torque with speed were balanced by the twist of the steel wire suspension, and were observed by a scale on the circumference of the wheel  $kl$ . The number of revolutions of the paddles was recorded automatically on a chronograph drum driven by a worm gear from the spindle  $f$ . The rise of temperature was recorded on the same sheet by an observer watching the thermometer and pressing a key at the moment when the mercury passed each division of the scale. The paddles were made very light and rigid, in order to reduce their water-equivalent, and were arranged to give the greatest possible uniformity of torque and efficiency of stirring. The lower part of the calorimeter was surrounded by a water jacket at a definite temperature in order to protect it from draughts and to make the heat-loss consistent. The heat-loss at any temperature was estimated by observing the rate of rise of temperature in subsidiary experiments when the paddles were driven at a much slower rate than in the main series of observations. It was found possible to obtain reliable observations in this way over a range from  $5^\circ$  to  $35^\circ\text{C.}$  about 14 times greater than in Joule's experiments, owing to the greater rate of work supply. But some of the observations were vitiated by deposition of dew on the calorimeter at the lower limit, and the heat-loss at the upper limit was rendered somewhat uncertain by upward convection currents from the heated calorimeter, which could not be completely enclosed. That Rowland's calorimetric observations were more accurate than those of any previous observer was clearly indicated by the fact that they conclusively demonstrated the diminution of the specific heat of water with rise of temperature from  $5^\circ$  to  $30^\circ\text{C.}$ , which had never been suspected, and has since been confirmed with remarkable precision.

Rowland was the first to appreciate the importance of reducing results for the mechanical equivalent to the absolute scale of temperature in place of the arbitrary scale given by a particular mercury thermometer. He considered that the comparison of his mercury thermometers with the air thermometer was the most difficult part of the investigation, and estimated the limit of accuracy at only 1 in 500 on this account; especially as the thermometers could not be compared under the actual conditions of

the experiments, with the temperature rising at the rate of nearly  $1^\circ\text{C.}$  per minute, owing to the excessive lag of the air thermometer and the time required for taking readings. Nevertheless, the probable accuracy of his result, namely, 4.179 joules per gm.cal. at  $20^\circ\text{C.}$ , the middle point of his range, may be taken as at least 1 in 2,000, since it was only raised to 4.181 by an elaborate comparison of his thermometers with Paris standards by Day, and with the platinum thermometer by Griffiths. Some 20 years later his result at  $20^\circ\text{C.}$  was further confirmed by the continuous electric method already described, in terms of the standard ohm and the Clark standard cell. By that time the absolute value of the ohm was known to at least 1 in 5,000, but that of the Clark cell was more doubtful, and was accordingly determined by R. O. King (*Phil. Trans.* 1902) using a special form of electrodynamicometer which he set up for the purpose. The accuracy of this instrument has since been confirmed by Norman Shaw (*Phil. Trans.* 1915), who employed it without any alteration for a similar determination of the absolute value of the Weston standard cell. Including all known corrections for the values of the electric units since ascertained, the electric method gives 4.178 joules, agreeing closely with Rowland's uncorrected result for the absolute value of the gm.cal.  $^\circ\text{C.}$  at  $20^\circ\text{C.}$  The corresponding value for the mean gm.cal.  $0^\circ$  to  $100^\circ\text{C.}$  would be 4.185 joules according to Table I. This also agrees very closely with the value 4.184 joules for the mean calorie as directly obtained by Reynolds and Moorby (*Phil. Trans.* 1897) with a 100 h.p. steam engine, using a Froude-Reynolds brake, in which the water was heated from near  $0^\circ\text{C.}$  to  $100^\circ\text{C.}$  This agreement may be regarded as confirming the variation of the specific heat of water as given by equation (6). It is usual, however, to take the round number 4.180 joules as the equivalent to the gm. calorie at  $20^\circ\text{C.}$ , giving greater weight to Rowland's corrected result. A very accurate determination of the gm. calorie in joules has recently been made by Laby and Hercus (*Phil. Trans. A.* 1927) between  $15^\circ$  and  $20^\circ$  by a steady flow method, in which the work was directly measured in mechanical units. They give the value 4.1809 joules for the gm. calorie at  $20^\circ\text{C.}$ , but it is uncertain how far the last figure may be regarded as significant.

For special methods commonly employed in the determination of the heats of combustion and calorific values of fuels, see article THERMOCHEMISTRY. For specific heats of gases and vapours, see articles HEAT, THERMODYNAMICS and VAPORIZATION. (H. L. C.)

**CALOVIUS** (1612–1686) (the latinized name of Abraham Calan), German Lutheran divine, was born at Mohrungen, East Prussia, on April 16, 1612. After studying at Königsberg, in 1650 he was appointed professor of theology at Wittenberg, where he afterwards became general superintendent and primarius. He died there on Feb. 25, 1686. Calovius was the powerful champion of Lutheran orthodoxy in the 17th century. He opposed Catholics, Calvinists, and Socinians, attacked in particular the reconciliation policy or "syncretism" of Georg Calixtus. His chief dogmatic work, *Systema locorum theologicorum* (1655–77), represents the climax of Lutheran scholasticism. His *Biblia Illustrata* was written to refute the statements made by Hugo Grotius in his Commentaries. His *Historia Syncretistica* (1682) was suppressed.

**CALPURNIA**, wife of Julius Caesar, was the daughter of L. Calpurnius Piso, consul in 58 B.C. She married Caesar in 59. Alarmed by the rumours of conspiracy current before Caesar's murder, she did her best to dissuade him from going to the Senate-House on the 15th of March 44. After the murder, she secretly moved his money and private papers to Anthony's house.

See Appian, *B.C.* II, 14, 115, 125; Plutarch, *Caesar*; Suetonius, *Caesar*, 27; *C.I.L.* VI, 14211.

**CALPURNIUS, TITUS**, Roman bucolic poet, surnamed SICULUS, probably flourished during the reign of Nero. Eleven eclogues have reached us under his name, of which the last four, from metrical considerations and express ms. testimony, are now generally attributed to Nemesianus (*q.v.*) who lived in the time of the emperor Carus and his sons (latter half of the 3rd century

A.D.). We gather from the poems (in which he is obviously represented by "Corydon") that Calpurnius was in poor circumstances and was on the point of emigrating to Spain, when "Meliboeus" came to his aid and helped him to a post at Rome. The time at which Calpurnius lived has been much discussed, but the references to the emperor seem to point to the time of Nero. Meliboeus has been variously identified, but what is known of Calpurnius Piso fits in with what is said of Meliboeus by the poet. His claim is further supported by the poem *De Laude Pisonis* (ed. C. F. Weber, 1859), which there is considerable reason for attributing to Calpurnius.<sup>1</sup> Further, the similarity between the two names can hardly be accidental; it is suggested that the poet may have been adopted by the courtier, or that he was the son of a freedman of Piso. The attitude of the author of the *Laus* towards the subject of the panegyric seems to show less intimacy than the relations between Corydon and Meliboeus in the eclogues, and there is internal evidence that the *Laus* was written during the reign of Claudius (Teuffel-Schwabe, *Hist. of Rom. Lit.* § 306,6).

The two short hexameter poems in an Einsiedeln ms., obviously belonging to the time of Nero, if not written by Calpurnius, were imitated from him.

Although there is nothing original in Calpurnius, he is "a skilful literary craftsman." Of his models the chief is Virgil, of whom (under the name of Tityrus) he speaks with great enthusiasm; he is also indebted to Ovid and Theocritus. Calpurnius is "a fair scholar, and an apt courtier, and not devoid of real poetical feeling. The bastard style of pastoral cultivated by him, in which the description of nature is made the writer's pretext, while ingenious flattery is his real purpose, nevertheless excludes genuine pleasure, and consequently genuine poetical achievement. He may be fairly compared to the minor poets of the reign of Anne" (Garnett).

Calpurnius was first printed in 1471, together with Silius Italicus and has been frequently republished, generally with Grattius Faliscus and Nemesianus. The separate authorship of the eclogues of Calpurnius and Nemesianus was established by M. Haupt's *De Carminibus bucolicis Calpurnii et Nemesiani* (1854). Editions by H. Schenkl (1885), with full introduction and *index verborum*, and by C. H. Keene (1887), with introduction, commentary and appendix and by Giannatano (Naples, 1910), and by H. Schenkl in Postgate's *Corpus* (1920); English verse translation by E. J. L. Scott (1891); see H. E. Butler, *Post-Augustan Poetry* (Oxford, 1909), pp. 150 foll.; F. Skutsch in Pauly-Wissowa's *Realencyklopädie*, iii. I. (1897); C. Chiavoli, *Della vita e dell' Opere di T. Calpurnio Siculo* (Ragusa, 1921).

**CALTAGIRONE**, a city and episcopal see of the province of Catania, Sicily, situated 1,999 ft. above sea-level, 36 m. S.W. of Catania direct (55 m. by rail). Pop. (1921) town 30,845; commune 38,017. Extensive Sicel cemeteries have been explored to the north of the town, and a Greek necropolis of the 6th and 5th centuries B.C. has been found to the south-east. Remains of buildings of Roman date have also been discovered; but the name of the ancient city is unknown. The present name is a corruption of the Saracen *Kalat-al-Girche* (the castle of Girche, the chieftain who fortified it). Majolica is made here, and the town is prosperous.

**CALTANISSETTA**, a town and episcopal see of Sicily, the capital of a province of the same name, 60 m. S.E. of Palermo direct and 83 m. by rail, situated 1,930 ft. above sea-level. Pop. (1921), 46,405 (town); 60,086 (commune). The town is of Saracenic origin, and some ruins of the old castle (called *Pietraro*) still exist. The cathedral and the church of the former Jesuit college are interesting baroque buildings. There is a famous procession on Holy Thursday. It is the centre of the Sicilian sulphur industry and the seat of a royal school of mines. It is connected by a short branch with the main line from Palermoto Catania; and a railway to Caltagirone and Syracuse is in construction. Two miles east is the Norman abbey of S. Spirito.

**CALTROP** (from the Mid. Eng. *calketrappe*, probably derived from the Lat. *calx*, a heel, and *trappa*, late Lat. for a snare), an iron ball, used as an obstacle against cavalry, with four spikes so arranged that, however placed in or on the ground, one spike always points upwards. It is also the botanical name for several species of thistles.

<sup>1</sup>It has been variously ascribed to Virgil, Ovid, Lucan, Statius, and Saleius Bassus.

**CALUIRE-ET-CUIRE**, a town of eastern France, in the department of Rhone, 2½ m. N. by E. of Lyons. Pop. (1926), 12,557. It makes velvet, combs and pins and has copper and bronze foundries and nursery-gardens.

**CALUMET**, the name given by the French in Canada to the "peace-pipe" of the American Indians (Norm. Fr. *chalumet*, Lat. *calamus*, a reed). This pipe occupied among the tribes a position of peculiar symbolic significance, and was the object of profound veneration. It was smoked on all ceremonial occasions, even on declarations of war, but its special use was at the making of treaties of peace. It was usually about 2½ ft. long, and in the west the bowl was made of red pipestone (catlinite). The pipe stem was of reed decorated with eagles' quills or women's hair. Native tobacco mixed with willow-bark or sumac leaves was smoked. The pipe was offered as a supreme proof of hospitality to distinguished strangers, and its refusal was regarded as a grievous affront. In the east and south-east the bowl was of white stone, sometimes pierced with several stem holes so that many persons might smoke at once.

See Joseph D. Macguire, "Pipes and Smoking Customs of the American Aborigines" in *Smithsonian Report* (American Bureau of Ethnology) for 1897, vol. i.; and authorities quoted in *Handbook of American Indians* (Washington, 1907).

**CALUMPIT**, a municipality (with administration centre and 23 *barrios* or districts) of the province of Bulacan, Luzon, Philippine Islands, at the junction of the Quiñgua and Pampanga rivers, about 25 m. N.W. of Manila. Pop. (1918) 14,844, of whom only 7 were whites. It is on the Manila and Dagupan railway and the bridge across the Pampanga at this point is one of the longest in the Philippines. The surrounding fertile plain produces rice, sugar, corn and a variety of fruits. The market here is famous. In 1918 it had 9 manufacturing establishments, with output valued at 45,500 pesos, and 24 sugar-mills and 650 household industry establishments with output valued at 166,400 pesos. Of the 12 schools, 11 were public. Much of the community was destroyed by insurgents in 1899. The language spoken is Tagalog.

**CALVADOS**, a department of north-western France, formed in 1790 out of Bessin, Cinglais, Hiémois, Bocage, the Campagne de Caen, Auge and the western part of Lieuvin. Pop. (1926) 390,492. Area, 2,197 sq.m. It received its name from a ledge of rocks, stretching along the coast for a distance of about 15 m. between the mouths of the rivers Orne and Vire. It is bounded north by the English channel, east by the department of Eure, south by that of Orne, west by that of Manche. In the south-west are the hills of Normandy (maximum height 1,197 ft.) which run in a north-westerly direction and cross a portion of the *Bocage*—a region of Devonian, Silurian and Cambrian rocks related structurally to the Armorican massif. The remainder of the department is low-lying and is drained by numerous streams. The deep valleys of the lower courses of the Orne and the Touques suggest that the slope was once greater than it is at present and a recent subsidence as elsewhere in the English channel has led to the formation of estuaries. The *Campagne de Caen* is a region of Jurassic rocks noted for its horse-breeding. In the north-west and east are Cretaceous rocks. Here is good pasture land and butter, eggs and cheese (Camembert, Livarot, Pont l'Évêque) are exported. The chief crops are wheat, oats, barley, colza and potatoes. The orchards of Auge and Bessin produce good cider and cider brandy (known as "Calvados") is distilled. The spinning and weaving of wool and cotton are the chief industries. There are also iron-mines, paper-mills, oil-mills, tanneries, saw-mills, ship-building yards, rope-works, dye-works, distilleries and bleach-fields, scattered throughout the department, and building stone, slate and lime are plentiful. There are many fishing villages, lobster, oyster, herring and mackerel fisheries being important. Trouville is the chief of the numerous coast resorts. Caen and Honfleur are the most important commercial ports. There is a canal 9 m. in length from Caen to Ouistreham on the coast.

The department is served by the Ouest-État railway. It is divided into the four *arrondissements* (38 cantons, 763 communes) of Caen, Bayeux, Lisieux and Vire. Caen, the capital, is the seat of a court of appeal and the centre of an *académie* (educational

division). The department forms the diocese of Bayeux, in the ecclesiastical province of Rouen, and belongs to the region of the III. Army Corps. The other principal towns are Falaise, Lisieux, Conde-sur-Noireau, Vire, Honfleur and Trouville (*q.v.*).

Caen has fine Romanesque and Gothic churches, St. Étienne, La Trinité, St. Pierre; and fine Gothic churches occur elsewhere, particularly at St. Pierre-sur-Dives, Lisieux, Bayeux, Norrey, a good example of the Norman-Gothic style, and Tour-en-Bessin, in which Romanesque and Gothic architecture are mingled. Fontaine-Henri has a château of the 15th and 16th centuries. The castle at Falaise is an important historic monument.

**CALVART, DENIS** (1540–1619), Flemish painter, was born at Antwerp. After studying landscape-painting in his native city he went to Bologna, where he perfected himself in the anatomy of the human form under Prospero Fontana, and so completely lost the mannerism of Flemish art that his paintings appear to be the work of an Italian. From Bologna he went to Rome, where he assisted Lorenzo Sabbatini (1533–1577) in his works for the papal palace, and devoted much of his time to copying and studying the works of Raphael. He ultimately returned to Bologna and founded a school, of which the greatest ornaments are Guido and Domenichino.

**CALVARY**, the scene of Christ's crucifixion; the word is the English form of the Vulgate, *Calvaria*, Greek *κράνιον*, "skull," Hebrew, Golgotha. The name is applied to a sculptured representation of the Crucifixion, either inside a church or in the open air. Important examples of the latter are the Sacro Monte (1486) at Varallo in Piedmont, and those at Guimiliau (1581), Plougastel (1602), St. Thegonnec (1610) and Pleyben, near Quimper (1670), in Brittany, all in good preservation.

**CALVÉ, EMMA** (1864– ), operatic singer, was born at Decazeville, Aveyron, in 1864, and trained in Paris, making her first important appearance in opera at Brussels in 1882. She sang mainly in Paris for some years, but in 1892 she came to London and achieved immediate fame and popularity at Covent Garden, more especially by her wonderful Carmen (in Bizet's opera), a part with which her name will always be associated. She sang at the Metropolitan and Manhattan opera houses in New York; she lectured on singing in the United States in the summer of 1927.

**CALVERLEY, CHARLES STUART** (1831–1884), English poet and wit, and the literary father of what may be called the university school of humour, was born at Martley in Worcestershire on Dec. 22, 1831, and died on Feb. 17, 1884. His father, the Rev. Henry Blayds, resumed in 1852 the old family name of Calverley which his grandfather had exchanged for Blayds in 1807. Charles Blayds went up to Balliol from Harrow in 1850. At Oxford he was a universal favourite, a delightful companion, a brilliant scholar and the playful enemy of all "dons." In 1851 he won the Chancellor's prize for Latin verse but a year later he took his name off the books, to avoid the consequences of a 'college escapade, and migrated to Christ's college, Cambridge. Here he was again successful in Latin verse. In 1856 he took second place in the first class in the Classical Tripos. He was elected fellow of Christ's (1858), published *Verses and Translations* in 1862, and was called to the bar in 1865. Owing to an accident while skating he was prevented from following up a professional career, and during the last years of his life he was an invalid. His *Translations into English and Latin* appeared in 1866; his *Theocritus translated into English Verse* in 1869; *Fly Leaves* in 1872; and *Literary Remains* in 1885. His sparkling, dancing verses, which have had many clever imitators, are still without a rival in their own line.

His *Complete Works*, with a biographical notice by Sir W. J. Sendall, appeared in 1901.

**CALVERT**, the name of three English artists: CHARLES (1785–1852), a well-known landscape painter; EDWARD (1803–1883), an important wood-engraver and follower of Blake; and FREDERICK, an excellent topographical draughtsman, whose work in water-colour is represented at the Victoria and Albert Museum, London, and who published a volume of *Picturesque Views in Staffordshire and Shropshire* (1830).

**CALVERT, FREDERICK CRACE** (1819–1873), English chemist, was born in London on Nov. 14, 1819. From about

1836 till 1846 he lived in France. On his return to England he settled in Manchester as a consulting chemist, and was appointed professor of chemistry at the Royal Institution in that city. He gave much attention to the manufacture of coal-tar products, and particularly carbolic acid, for the production of which he established large works at Manchester in 1865. He died in Manchester on Oct. 24, 1873.

**CALVERT, SIR HARRY, BART.** (1763–1826), British general, was born in 1763 at Hampton, near London. He was educated at Harrow, and in 1778 entered the army. In the following year he served with his regiment in America, being present at the siege of Charleston, and from 1781 to 1783 was a prisoner of war. He next saw active service in 1793–94 in the Low Countries, where he was aide-de-camp to the duke of York. In 1799, he was made adjutant-general, holding the post till 1818, and did much to improve the administration of the army medical and hospital department; he introduced regimental schools, developed the two existing military colleges and helped to found the duke of York's school, Chelsea. He was made a G.C.B. (1815), and, on retiring from office, received a baronetcy (1818). In 1820 he was made governor of Chelsea hospital. He died on Sept. 3, 1826, at Middle Claydon, Buckinghamshire.

*The Journals and correspondence of General Sir Harry Calvert . . . comprising the Campaigns in Flanders in 1793–94* were edited by his son, Sir Harry Verney (1853).

**CALVES' HEAD CLUB**, a club established shortly after his death in derision of the memory of Charles I. Its chief meeting was held each Jan. 30, the anniversary of the King's execution, when the dishes served were a cod's head to represent the individual, Charles Stuart; a pike representing tyranny; a boar's head representing the King preying on his subjects; and calves' heads representing Charles as King and his adherents. After the Restoration the club met secretly. It survived till 1734, when the diners were mobbed, and the riot which ensued put a stop to the meetings.

**CALVI**, a sea-port of north-west Corsica, having railway connections with Île Rousse eastwards along the coast. Pop. (1926) 2,517. Situated on the Bay of Calvi, it is the nearest Corsican port to France, being 109m. from Antibes; the harbour, however, is exposed to the east and north-east winds.

Calvi was founded in 1268, and in 1278 passed into the hands of the Genoese. In recognition of its repulsion of the united attacks of the French and the Turks in 1553, the Genoese senate caused the words *Civitas Calvi semper fidelis* to be carved on the chief gate of the city, which still preserves the inscription. In 1794 Calvi was captured by the British, but it was re-taken by the Corsicans in the following year. The old palace of the Genoese governor is used as barracks. The modern town lies at the foot of a rock, on which stands the old town with its steep rock-paved streets and fortified walls, commanded by the Fort Muzello. Fishing is carried on, and some timber, oil, wine and lemons are exported. Calvi claims to be the birthplace of Columbus (1451).

**CALVIN, JOHN** (1509–1564), Swiss divine and reformer, was born at Noyon, in Picardy, on July 10, 1509, and was the second son of Gérard Cauvin or Calvin, a notary-apostolic and procurator-fiscal for the lordship of Noyon, and of Jeanne le Franc, daughter of an innkeeper at Cambrai. (The family name of Calvin seems to have been written indifferently Cauvin, Chauve, Chauvin, Calvus, Calvinus. In the contemporary notices of Gérard and his family, in the capitial registers of the cathedral at Noyon, the name is always spelt Cauvin. The anagram of Calvin is Alcuin, and this, in its Latinized form Alcuinus, appears in two editions of his *Institutio* as that of the author [Audin, *Vie de Calvin*, i. 520]. The syndics of Geneva address him in a letter written in 1540, and still preserved, as "Docteur Caulvin." In his letters written in French he usually signs himself "Jean Calvin." He affected the title of "Maître," for what reason is not known.)

Of Calvin's early years little is known. Destined for an ecclesiastical career, he was educated in the household of the noble family of Hangest de Montmor. In May 1521 he was appointed to a chaplaincy in the cathedral of Noyon, and received the tonsure. Calvin accompanied the Hangests to Paris in Aug. 1523, being

enabled to do so by the income received from his benefice. He attended as an out-student the Collège de la Marche, at that time under the regency of Mathurin Cordier, who in later days taught at Neuchâtel, and died in Geneva in 1564. Calvin dedicated to him his *Commentary on the First Epistle to the Thessalonians*. From the Collège de la Marche he removed to the Collège de Montaigu, where the atmosphere was more ecclesiastical. (Pierre de Montaigu refounded this institution in 1388. Erasmus and Ignatius Loyola also studied here.) In the college disputations he gave fruitful promise of that consummate excellence as a reasoner in the department of speculative truth which he afterwards displayed. Among his friends were the Hangests (especially Claude), Nicolas and Michel Cop, sons of the king's Swiss physician, and his own kinsman Pierre Robert, better known as Olivétan. Such friendships contradict the legend that he was an unsociable misanthrope. The canons at Noyon gave him in Sept. 1527 the curacy of St. Martin de Marteville, which he exchanged in July 1529 for the cure of Pont l'Évêque. But Calvin was not destined to become a priest. Gérard Cauvin began to suspect that the law offered to a youth of his talents and industry a more promising sphere. He was also now out of favour with the cathedral chapter at Noyon. It is said that John himself, on the advice of Olivétan, the first translator of the Bible into French, had begun to study the Scriptures and to dissent from the Roman worship. He readily complied with his father's suggestion, and removed from Paris to Orleans (March 1528) in order to study law under Pierre Taisan de l'Étoile, the most distinguished jurisconsult of his day. Other studies, however, besides those of law occupied him, and moved by the humanistic spirit of the age, he eagerly developed his classical knowledge. His friends here were Melchior Wolmar, François Daniel, François de Connam and Nicolas Duchemin; to these his earliest letters were written. From Orleans Calvin went to Bourges in the autumn of 1529 to continue his studies under the brilliant Italian, Andrea Alciati (1492-1550). His friend Daniel went with him, and Wolmar followed a year later. By Wolmar Calvin was taught Greek, and introduced to the study of the New Testament in the original.

Twelve years had elapsed since Luther had published his theses against indulgences. In France there had not been as yet any overt revolt against the Church of Rome, but multitudes were in sympathy with the reformers' ideals. Calvin's own record of his "conversion" is so scanty that it is extremely difficult to trace his religious development with any certainty. But it seems probable that at least up to 1532 he was far more concerned about classical scholarship than about religion.

His residence at Bourges was cut short by the death of his father in May 1531. He went to Paris, where the "new learning" was now at length ousting the mediaeval scholasticism from the university. He lodged in the Collège Fortet, reading Greek with Pierre Danès and beginning Hebrew with François Vatable. In April 1532 Calvin published his commentary in Latin on Seneca's tract *De Clementia*.

Soon afterwards Calvin returned to Orleans. He visited Noyon in Aug. 1533, and by October of the same year was settled again in Paris. Here and now his destiny became certain. The conservative theology was becoming discredited, and humanists like Jacques Lefèvre de Étaples (Faber Stapulensis) and Gérard Roussel were favoured by the court under the influence of Margaret of Angoulême, queen of Navarre and sister of Francis I. Calvin's old friend, Nicolas Cop, had just been elected rector of the university and had to deliver an oration according to custom in the church of the Mathurins, on the feast of All Saints. The oration (certainly influenced but hardly composed by Calvin) was in effect a defence of the reformed opinions, especially of the doctrine of justification by faith alone. To the period between April 1532 and November 1533, and in particular to the time of his second sojourn at Orleans, we may assign the great change in Calvin which he describes (*Praef. ad Psalmos*; opera xxxi. 21-24) as his "sudden conversion" and attributes to direct divine agency. But Cop's address was followed by a summons to the orator to appear before the parlement of Paris, and as he failed to secure the support either of the king, or of the university, he fled to Basle. An

attempt was made at the same time to seize Calvin who, being forewarned of the design, also made his escape. He went to Noyon, but, proceedings against him being dropped, soon returned to Paris. He left the city again about New Year of 1534 and became the guest of Louis du Tillet, a canon of the cathedral, at Angoulême. Here, in du Tillet's splendid library, he began the studies which resulted in his great work, the *Institutes*, and paid a visit to Nérac, where the venerable Lefèvre, whose revised translation of the Bible into French was published about this time, was spending his last years under the kindly care of Margaret of Navarre.

Up to this time Calvin's work for the evangelical cause was not so much that of the public preacher or reformer as that of the retiring but influential scholar and adviser. Now, however, he had to decide whether, like Roussel and other of his friends, he should strive to combine the new doctrines with a position in the old church, or whether he should definitely break away from Rome. His mind was made up, and on May 4 he resigned his chaplaincy at Noyon and his rectorship at Pont l'Évêque. Towards the end of the same month he was arrested and suffered two short terms of imprisonment, the charges against him being not strong enough to be pressed. His movements now become difficult to trace, but he visited Paris, Orleans and Poitiers.

The Anabaptists of Germany had spread into France, and among other notions which they had spread abroad was that of a sleep of the soul after death. To Calvin this notion appeared so pernicious that he composed a treatise of refutation of it, under the title of *Psychopannychia*. The preface to this treatise is dated Orleans 1534, but it was not printed till 1542. At Poitiers, in a grotto near the town, he for the first time celebrated the communion in the Evangelical Church of France, using a piece of rock as a table.

The year 1534 was thus decisive for Calvin. From this time forward his influence became supreme, and all who had accepted the reformed doctrines in France turned to him for counsel and instruction. Renan, no prejudiced judge, pronounces him "the most Christian man of his time," and attributes to this his success as a reformer. But his life was in danger, and, in company with his friend Louis du Tillet, whom he had again gone to Angoulême to visit, he set out for Basle. Here Calvin was welcomed by the band of scholars and theologians who made that city the Athens of Switzerland, and especially by Oswald Myconius, the chief pastor, Pierre Viret and Heinrich Bullinger. Under the guidance of Sebastian Münster, Calvin now gave himself to the study of Hebrew.

Francis I., desirous to continue the suppression of the Protestants, but anxious, because of his strife with Charles V., not to break with the Protestant princes of Germany, instructed his ambassador to assure these princes that it was only against Anabaptists, and other parties who called in question all civil magistracy, that his severities were exercised. Calvin, indignant at the calumny which was thus cast upon the reformed party in France, hastily prepared for the press his *Institutes of the Christian Religion*. The work was dedicated to the king, and Calvin says he wrote it in Latin that it might find access to the learned in all lands. Soon after it appeared he set about translating it into French, as he himself attests in a letter dated October 1536. This sets at rest a question at one time much agitated, whether the book appeared first in French or in Latin. The earliest French edition known is that of 1540, and this was after the work had been much enlarged, and several Latin editions had appeared. In its first form the work consisted of only six chapters, and was intended merely as a brief manual of Christian doctrine. The chapters follow a traditional scheme of religious teaching: (1) The Law (as in the Ten Words), (2) Faith (as in the Apostles' Creed), (3) Prayer, (4) the Sacraments; to these were added (5) False Sacraments, (6) Christian liberty, ecclesiastical power and civil administration. The closing chapters of the work are more polemical than the earlier ones. His indebtedness to Luther is of course great, but his spiritual kinship with Martin Bucer of Strasbourg is even more marked. The book appeared anonymously, the author having, as he himself says, nothing in view beyond fur-

nishing a statement of the faith of the persecuted Protestants. In this work, written at the age of 26, we find a complete outline of the Calvinist theological system. Nor is there any reason to believe that he ever changed his views on any essential point from what they were at the period of its first publication. It exercised a prodigious influence upon the opinions and practices both of contemporaries and of posterity.

After a short visit (April 1536) to the court of Renée, duchess of Ferrara (cousin to Margaret of Navarre), Calvin returned through Basle to France to arrange his affairs before finally taking farewell of his native country. His intention was to settle at Strasbourg or Basle, and to devote himself to study. Unable, in consequence of the war between Francis I. and Charles V., to reach Strasbourg by the ordinary route, he journeyed to Lyons and so to Geneva, making for Basle. In Geneva his progress was arrested by the "formidable obtestation" of Guillaume Farel (*Præf. ad Psalmos*) who had succeeded in planting the evangelical standard at Geneva. Anxious to secure the aid of such a man as Calvin, he entreated him on his arrival to devote himself to the work in that city. Calvin, after some hesitation, consented, hurried to Basle, transacted some business, and returned to Geneva in Aug. 1536. He at once began to expound the epistles of St. Paul in the church of St. Pierre, and after about a year was also elected preacher by the magistrates with the consent of the people. His services were at first rendered gratuitously.

Calvin was in his 28th year when he settled at Geneva; and in this city the rest of his life, with the exception of a brief interval, was spent. The post to which he was thus called was not an easy one. Though the people of Geneva had cast off the obedience of Rome, it was largely a political revolt against the duke of Savoy, and they were still (says Beza) "but very imperfectly enlightened in divine knowledge." This laid them open to the incursions of those fanatical teachers, whom the excitement attendant upon the Reformation had called forth, and who hung mischievously upon the rear of the reforming body. To obviate the evils thence resulting, Calvin, in union with Farel, drew up a condensed statement of Christian doctrine consisting of 21 articles. This the citizens were summoned, in parties of ten each, to profess and swear to as the confession of their faith. As the people took this oath in the capacity of *citizens*, we may see here the basis laid for that theocratic system which subsequently became peculiarly characteristic of the Genevan polity. Calvin and his coadjutors were solicitous to establish schools throughout the city, and to enforce attendance; and as he had no faith in education apart from religious training, he drew up a catechism of Christian doctrine which was an obligatory part of the curriculum. Of the troubles which arose from fanatical teachers, the chief proceeded from the efforts of the Anabaptists; a public disputation was held on March 16-17, 1537, and so excited the populace that the Council of Two Hundred stopped it, declared the Anabaptists vanquished and drove them from the city. About the same time the peace of Calvin and his friends was much disturbed and their work interrupted by Pierre Caroli, chief pastor at Lausanne. Calvin brought Caroli before the commissioners of Berne on a charge of advocating prayers for the dead as a means of their earlier resurrection. Caroli brought a counter-charge against the Geneva divines of Sabellianism and Arianism. In a synod held at Berne the matter was fully discussed, a verdict was given in favour of the Geneva divines, and Caroli deposed from his office and banished. Two brief anti-Roman tracts, one entitled *De fugiendis impiorum sacris*, the other *De sacerdotio papali abjiciendo*, were also published by Calvin early in this year.

But the austerity, both of ritual and living, enjoined by Calvin and his endeavour to effect the complete freedom of the Church from State control, was deeply resented. He and his colleagues refused to administer the sacrament in the Bernese form, *i.e.*, with unleavened bread, and on Easter Sunday, 1538, declined to do so at all because of the popular tumult. For this they were banished from the city. They went at first to Berne, and soon after to Zürich, where they pleaded their cause before a synod of Swiss pastors, and declared that they would yield in the matter of ceremonies so far as to employ unleavened bread in the eucharist, to

use fonts in baptism and to allow festival days, provided the people might pursue their ordinary avocations after public service. These Calvin regarded as matters of indifference, provided the magistrates did not make them of importance, by seeking to enforce them; and he was the more willing to concede them, because he hoped thereby to meet the wishes of the Bernese brethren whose ritual was less simple than that established by Farel at Geneva. But he and his colleagues insisted, on the other hand, that for the proper maintenance of discipline, there should be a division of parishes—that excommunications should be permitted, and should be under the power of elders chosen by the council, in conjunction with the clergy—that order should be observed in the admission of preachers—and that only the clergy should officiate in ordination by the laying on of hands. It was proposed that the sacrament of the Holy Communion should be administered more frequently, at least once every month, and that congregational singing of psalms should be practised in the churches. On these terms the synod interceded with the Genevese to restore their pastors; but through the opposition of some of the Bernese (especially Peter Kuntz, the pastor of that city) this was frustrated, and a second edict of banishment was the only response.

Calvin and Farel betook themselves to Basle, where they soon after separated, Farel to go to Neuchâtel and Calvin to Strasbourg, where he remained until the autumn of 1541. These years were not the least valuable in his experience. In 1539 he attended Charles V.'s conference on Christian reunion at Frankfurt as the companion of Bucer, and in the following year he represented the city of Strasbourg at Hagenau and Worms. He was present also at the diet at Regensburg, where he formed with Melancthon a lifelong friendship. He also did something to relieve the persecuted Protestants of France. To this period we owe a revised and enlarged form of his *Institutes*, his *Commentary on the Epistle to the Romans*, and his *Tract on the Lord's Supper*. During his residence at Strasbourg he married, in Aug. 1540, Idelette de Bure, the widow of one Jean Stordeur of Liège, whom he had converted from Anabaptism. In her Calvin found, to use his own words, "the excellent companion of his life," a "precious help" to him amid his manifold labours and frequent infirmities. She died in 1549. Their only child, Jacques, born on July 28, 1542, lived only a few days.

During Calvin's absence disorder and irreligion had prevailed in Geneva. An attempt made by Cardinal Jacopo Sadoletto (1477-1547), bishop of Carpentras, to restore Roman Catholicism was frustrated by a letter written by Calvin at the desire of the Bernese authorities. The letter was a popular yet thoroughgoing defence of the whole Protestant position, perhaps the best apology for the Reformation that was ever written. While he was still at Strasbourg there appeared at Geneva a translation of the Bible into French, bearing Calvin's name, but in reality only revised and corrected by him from the version of Olivétan. Meanwhile his enemies in Geneva gradually lost power and office. Farel worked unceasingly for his recall. He returned to Geneva, where he was received with the utmost enthusiasm, on Sept. 13, 1541. He now determined to carry out his whole original scheme of reform, and to set up in all its integrity that form of church polity which he had carefully matured during his residence at Strasbourg. He now became the sole directive spirit in the Church at Geneva. Farel was retained by the Neuchâtelois, and Viret, soon after Calvin's return, removed to Lausanne.

He recodified the Genevan laws and constitution, and was the leading spirit in the negotiations with Berne that issued in the treaty of Feb. 1544. He spent much time in controversy, notably over the doctrine of predestination and election. His three chief opponents were Albert Pighius, who subsequently embraced his views, Jerome Bolsec, Sébastien Castellio and, greatest of all, Michael Servetus (*q.v.*). At Calvin's instance Servetus was arraigned for blasphemy, condemned, and burnt to death. Even though the opprobrium of this procedure must be shared by the Genevan fathers, the Swiss authorities, and some of the more famous reformers like Melancthon, who approved it, Calvin cannot be held guiltless of perpetrating a martyrdom that did much to sully the cause he had so greatly at heart.

Calvin was also involved in a protracted and somewhat vexing dispute with the Lutherans respecting the Holy Communion, which ended in the separation of the evangelical party into the two great sections of Lutherans and Reformed—the former holding that in the eucharist the body and blood of Christ are objectively and consubstantially present, and so are actually partaken of by the communicants, and the latter that there is only a virtual presence of the body and blood of Christ, and consequently only a spiritual participation thereof through faith. In addition to these controversies on points of faith, he was for many years greatly disquieted by opposition in Geneva to the ecclesiastical discipline which he had established there. His system of church polity was essentially theocratic; it assumed that every member of the State was also under the discipline of the Church; and he asserted that the right of exercising this discipline was vested exclusively in the consistory or body of preachers and elders. Calvin's views on Church discipline naturally brought him into conflict with the civil authority and with the people. But his courage, his perseverance and his earnestness at length prevailed and, before he died, his system of church polity was firmly established, not only at Geneva, but in other parts of Switzerland, and was adopted substantially by the Reformers in France and Scotland. The men whom he trained at Geneva carried his principles into almost every country in Europe. Nor was it only in religious matters that Calvin busied himself; he was consulted on every affair, great and small, that came before the council—on questions of law, police, economy, trade and manufactures, no less than on questions of doctrine and Church polity. To him the city owed her trade in cloths and velvets, from which so much wealth accrued to her citizens; sanitary regulations were introduced by him which made Geneva the admiration of all visitors; and in him she reverences the founder of her university. This institution was in a sense Calvin's crowning work. It added religious education to the evangelical preaching and the thorough discipline already established, and so completed the reformer's ideal of a Christian commonwealth.

Amidst these multitudinous cares and occupations, Calvin wrote many controversial and many exegetical works. We have from him expository comments or homilies on nearly all the books of Scripture, written partly in Latin and partly in French. Though naturally knowing nothing of the modern idea of a progressive revelation, his judiciousness, penetration and tact in eliciting his author's meaning, his precision, condensation and concinnity as an expositor, the accuracy of his learning, the closeness of his reasoning and the elegance of his style, all unite to confer a high value on his exegetical works. The series began with *Romans* in 1540 and ended with *Joshua* in 1564. In 1558–59, also, though in very ill health, he finally perfected the *Institutes*.

The incessant and exhausting labours to which Calvin gave himself could not but tell on his fragile constitution. On Feb. 16, 1564, he preached his last sermon, having with great difficulty found breath enough to carry him through it. On April 20 he made his will, on the 27th he received the Little Council, and on the 28th the Genevan ministers, in his sick-room; on May 2 he wrote his last letter—to his old comrade Farel, who hastened from Neuchâtel to see him once again. He spent much time in prayer and died quietly, in the arms of his faithful friend Theodore Beza, on the evening of May 27. The next day he was buried without pomp "in the common cemetery called Plain-palais," in a spot not now to be identified.

Calvin was of middle stature; his complexion was somewhat pallid and dark; his eyes, to the latest clear and lustrous, bespoke the acumen of his genius. He was sparing in his food and simple in his dress; he took but little sleep, and was capable of extraordinary efforts of intellectual toil. He had a most retentive memory and a very keen power of observation. He spoke without rhetoric, simply, directly, but with great weight. He had many acquaintances, but few close friends. If somewhat severe and irritable, he was at the same time scrupulously just, truthful and steadfast; he never deserted a friend or took an unfair advantage of an antagonist; and on befitting occasions he could be cheerful and even facetious among his intimates.

Though Calvin built his theology on the foundations laid by earlier reformers, and especially by Luther and Bucer, his peculiar gifts of learning, of logic and of style made him pre-eminently the theologian of the new religion.

Calvin's dominant thought is the infinite and transcendent sovereignty of God, to know whom is man's supreme end. God is known to man especially by the Scriptures, whose writers were "sure and authentic amanuenses of the Holy Spirit." While God is the source of all good, man is guilty and corrupt. The first man was made in the image of God, which not only implies man's superiority to other creatures, but indicates his original purity, integrity and sanctity. Through Adam's fall, depravity and corruption attach to all men. On account of such corruption all are deservedly condemned before God, by whom nothing is accepted save righteousness, innocence and purity. When it is said that we through Adam's sin have become obnoxious to the divine judgment, it is not to be taken as if we being ourselves innocent and blameless, bear the fault of his offence, but that, we having been brought under a curse through his transgression, he is said to have bound us. From him, however, not only has punishment overtaken us, but a pestilence instilled from him resides in us, to which punishment is justly due. Thus even infants, whilst they bring their own condemnation with them from their mothers' wombs, are bound not by another's but by their own fault. For though they have not yet brought forth the fruits of their iniquity, they have its seed; nay, their whole nature is a sort of seed of sin, therefore it cannot but be hateful to God (*Instit.* bk. ii. ch. i. sec. 8).

To redeem man from this state of corruption, the Son of God became incarnate. He took on Him the offices of prophet, priest and king, and by His humiliation, obedience and suffering unto death, followed by His resurrection and ascension to heaven, He has perfected His work and fulfilled all that was required in a redeemer of men, so that it is truly affirmed that He has merited for man the grace of salvation (bk. ii. ch. 13–17). But until a man is united to Christ, the benefits of Christ's work cannot be attained by him. This union is achieved through the special operation of the Holy Spirit in the faithful, who thus become partakers of His death and resurrection, so that the old man is crucified with Him and they are raised to a life of righteousness and holiness. Thus joined to Christ, the believer has life in Him and knows that he is saved, having the witness of the Spirit that he is a child of God, and having the promises, the certitude of which the Spirit had before impressed on the mind, sealed by the same Spirit on the heart (bk. iii. ch. 33–36). From faith springs repentance, proceeding from a sincere fear of God, and consisting in the mortification of the flesh and the old man within us and a vivification of the Spirit. Through faith also the believer receives justification, his sins are forgiven, he is accepted of God, and is held by Him as righteous, the righteousness of Christ being imputed to him. This imputed righteousness, however, is not disjoined from real personal righteousness, for regeneration and sanctification come to the believer from Christ no less than justification; the two blessings are not to be confounded, but neither are they to be disjoined. The assurance which the believer has of salvation he receives from the operation of the Holy Spirit; but this again rests on the divine choice of the man to salvation; and this falls back on God's eternal sovereign purpose, whereby He has predestined some to eternal life and some to eternal death. The former he effectually calls to salvation, and they are kept by Him in progressive faith and holiness unto the end (bk. iii. *passim*). The external means by which God unites men into the fellowship of Christ, and advances those who believe, are the Church and its ordinances, especially the sacraments. The Church universal is the multitude gathered from diverse nations, which though divided by time and place, agree in one common faith, and it is bound by the tie of the same religion; and wherever the word of God is sincerely preached, and the sacraments are duly administered, according to Christ's institute, there beyond doubt is a Church of the living God (bk. iv. ch. 1, sect. 7–11). Its permanent officers are pastors and teachers, to the former of whom it belongs to preside over the discipline of the Church, to administer the

sacraments, and to admonish the members; while the latter expound the Scriptures. With them are to be joined for the government of the Church certain pious men as a senate in each church; and to others, as deacons, is to be entrusted the care of the poor. The election of the officers is to be with the people, and those duly chosen are to be ordained by the laying on of the hands of the pastors (ch. 3, sect. 4-16). The sacraments are two—Baptism and the Lord's Supper. Baptism is the sign of initiation into the Church; it serves both for the confirmation of faith and as a confession before men. The Holy Communion is a spiritual feast where Christ attests that He is the life-giving bread, by which our souls are fed. That sacred communication of His flesh and blood whereby Christ transfuses into us His life, He in the Supper attests and seals; and that not by an empty sign but there He puts forth the efficacy of His Spirit whereby He fulfils what He promises. In the mystery of the Supper Christ is truly exhibited by the symbols of bread and wine; and so His body and blood, in which He fulfilled all obedience for the obtaining of righteousness for us, are presented. Christ is not affixed to the bread or in any way circumscribed; but whatever can express the true and substantial communication of the body and blood of the Lord, which is exhibited to believers under the said symbols is to be received, and that not as merely mentally received, but as enjoyed for the aliment of the eternal life (bk. iv. ch. 15, 17).

The course of time has substantially modified many of Calvin's positions. Even the churches which trace their descent from him no longer hold in their entirety his views on the magistrate as the preserver of church purity, the utter depravity of human nature, the non-human character of the Bible, the dealing of God with man. But his system had great value in the history of Christian thought. It appealed to and evoked a high order of intelligence, and its insistence on personal individual salvation has borne worthy fruit. So also its insistence on the chief end of man "to know and do the will of God" made for strenuous morality. Its effects are most clearly seen in Scotland, in Puritan England and in the New England States, but its influence was and is felt among peoples that have little desire or claim to be called Calvinist.

**BIBLIOGRAPHY.**—The standard edition of Calvin's works is that of the Strasbourg scholars, J. W. Baum, E. Cunitz, E. Reuss, P. Lobstein, A. Erichson (59 vols., 1863-1900). The last of these contains an elaborate bibliography also published separately at Berlin in 1900. The bulk of the writings was published in English by the Calvin Translation Society (48 vols., Edinburgh, 1843-55); the *Institutes* have often been translated. The early lives by Beza and Collodon are given in the collected editions. Among modern biographies are those by P. Henry, *Das Leben J. Calvins* (3 vols., Hamburg, 1835-44; Eng. trans. by H. Stebbing, London and New York, 1849); V. Audin, *Histoire de la vie, des ouvrages, et des doctrines de Calvin* (2 vols., Paris, 1841; Eng. trans. by J. McGill, London, 1843 and 1850), unfairly antagonistic; T. H. Dyer, *Life of John Calvin* (London, 1850); E. Stähelin, *Joh. Calvin, Leben und ausgewählte Schriften* (2 vols., Elberfeld, 1863); F. W. Kamp-schulte, *Joh. Calvin, seine Kirche und sein Staat in Genf* (2 vols., 1869, 1899, unfinished); Abel Lefranc, *La Jeunesse de Calvin* (Paris, 1888); E. Choisy, *La Théocratie à Genève au temps de Calvin* (Geneva, 1897); E. Doumergue, *Jean Calvin; les hommes et les choses de son temps* (17 vols., 1899-1927). See also A. M. Fairbairn, "Calvin and the Reformed Church" in the *Cambridge Modern History*, vol. ii. (1904); P. Schaff's *History of the Christian Church*, vol. vii. (1892), and R. Stähelin's article in Hauck-Herzog's *Realencyk. für prot. Theologie und Kirche*. Each of these contains a useful bibliography, as also does the excellent life by Professor Williston Walker, *John Calvin, the Organizer of Reformed Protestantism*, "Heroes of the Reformation" series (1906). See also C. S. Horne in *Mansfield Coll. Essays* (1909); L. Penning, *Life and Times of Calvin*, Eng. trans. by B. S. Berrington (1912).

**CALVINISTIC METHODISTS**, a body of Christians forming a church of the Presbyterian order and claiming to be the only denomination in Wales which is of purely Welsh origin. Its beginnings may be traced to the labours of the Rev. Griffith Jones (1684-1761), of Llanddowror, Carmarthenshire, whose sympathy for the poor led him to set on foot a system of circulating charity schools for the education of poor children. Griffith Jones's zeal appealed to the public imagination, and his powerful preaching exercised a widespread influence. An impressive announcement of the Easter Communion Service, made by the Rev. Pryce Davies, vicar of Talgarth, March 30, 1735, was the

means of awakening Howell Harris (1714-1773) of Trevecca, who became a fiery itinerant preacher. Jones, preaching at Llanddewi Brefi, Cardiganshire—the place at which the Welsh Patron Saint, David, first became famous—roused Daniel Rowland (1713-1790), curate of Llangeitho, who became an ardent apostle of the new movement. Naturally a fine orator, his new-born zeal gave an edge to his eloquence, and his fame spread abroad. About 1739 another prominent figure appeared: this was Howell Davies of Pembrokeshire, whose ministry was modelled on that of his master, Griffith Jones.

In 1736 Harris opened a school, Griffith Jones supplying him with books from his charity. He also set up societies, in accordance with the recommendations in Josiah Wedgwood's little book on the subject; and these exercised a great influence on the religious life of the people. By far the most notable of Harris's converts was William Williams (1717-1791), of Pant y Celyn, the great hymn-writer of Wales. He had been ordained deacon in the Church of England, 1740, but Whitefield recommended him to leave his curacies and go into the highways and hedges. In Jan. 1743, the friends of aggressive Christianity in Wales met at Wadford, near Caerphilly, Glam., in order to organize their societies. The meeting is known as the first Methodist Association—held eighteen months before John Wesley's first conference (June 25, 1744). Monthly meetings covering smaller districts were organized to consider local matters, the transactions of which were to be reported to the Quarterly Association, to be confirmed, modified, or rejected. Exhorters were divided into two classes—public, who were allowed to itinerate as preachers and superintend a number of societies; private, who were confined to the charge of one or two societies. The societies were distinctly understood to be part of the established church, as Wedgwood's were, and every attempt at estranging them therefrom was sharply repressed; but persecution made their position anomalous. They did not accept the discipline of the Church of England, so the plea of conformity was a feeble defence; nor had they taken out licences, so as to claim the protection of the Toleration Act. Harris's ardent loyalty to the Church of England, after three refusals to ordain him, and his personal contempt for ill-treatment from persecutors, were the only things that prevented separation.

A controversy on a doctrinal point—"Did God die on Calvary?"—raged for some time, the principal disputants being Rowland and Harris; and in 1751 it ended in an open rupture, which threw the Connexion first into confusion and then into a state of coma. The societies split up into Harrisites and Rowlandites, and it was only with the revival of 1762 that the breach was fairly repaired. This revival is a landmark in the history of the Connexion. Williams of Pant y Celyn had just published a little volume of hymns, the singing of which inflamed the people. This led the bishop of St. David's to suspend Rowland's licence, and Rowland had to confine himself to a meeting-house at Llangeitho. This place became the Jerusalem of Wales. A remarkable event in the history of Welsh Methodism was the publication in 1770 of an annotated Welsh Bible by the Rev. Peter Williams, a forceful preacher, and an indefatigable worker, who had joined the Methodists in 1746, after being driven from several curacies. It gave birth to a new interest in the Scriptures, being the first definite commentary in the language. The ignorance of the people of the north made it very difficult for Methodism to spread there, until the advent of the Rev. Thomas Charles (1755-1814), who, having spent five years in Somersetshire as curate of several parishes, returned to Bala and joined the Methodists in 1784. His circulating charity schools and then his Sunday schools gradually made the north a new country. In 1791 the Bala Association was disturbed by the proceedings which led to the expulsion of Peter Williams from the Connexion, in order to prevent him from selling among the Methodists Bibles with Sabellian marginal notes.

**Separation from the Church of England.**—About 1795, persecution led the Methodists to take the first step towards separation from the Church of England. Heavy fines made it impossible for preachers in poor circumstances to continue without claiming the protection of the Toleration Act, and the meeting-

houses had to be registered as dissenting chapels. Moreover, until 1811 they had no ministers ordained by themselves; their growth in numbers and the scarcity of ministers to administer the Sacrament (three in north Wales) made the question of ordination a matter of urgency. The south Wales clergy who regularly itinerated were dying out; the majority of those remaining itinerated but irregularly, and were most of them against the change. The lay element, with the help of Charles and a few other stalwarts, carried the matter through—ordaining nine at Bala in June, and thirteen at Llandilo in August. In 1823, the *Confession of Faith* was published; it is based on the *Westminster Confession* as "Calvinistically construed," and contains 44 articles. The Connection's *Constitutional Deed* was formally completed in 1826.

The question of ministerial training then arose. Candidates for the Connexional ministry were compelled to shift for themselves until 1837, when Lewis Edwards (1809-1887) and David Charles (1812-1878) opened a school for young men at Bala. North and south alike adopted it as their college, the associations contributing a hundred guineas each towards the education of their students. In 1842, the south Wales association opened a college at Trevecca, leaving Bala to the north. The latter was now a purely theological college, the students of which were sent to the university colleges for their classical training. In 1905 Mr. David Davies of Llandinam—one of the leading laymen in the Connexion—offered a large building at Aberystwyth as a gift to the denomination for the purpose of uniting north and south in one theological college; but in the event of either association declining the proposal, the other was permitted to take possession, giving the association that should decline the option of joining at a later time. The association of the south accepted, and that of the north declined, the offer; Trevecca College was turned into a preparatory school on the lines of a similar institution set up at Bala in 1891.

**Constitution and Doctrine.**—The constitution of the denomination is a mixture of Presbyterianism and Congregationalism; each church manages its own affairs and reports to monthly meetings which are made up of all the officers of the churches comprised in each, and are split up into districts for the purpose of a more local co-operation of the churches. The monthly meetings appoint delegates to the quarterly associations, of which all officers are members. The associations of north and south are distinct institutions, deliberating and determining matters pertaining to them in their separate quarterly gatherings. For the purpose of a fuller co-operation in matters common to both, a general assembly (meeting once a year) was established in 1864. This is a purely deliberative conclave, worked by committees, and all its legislation has to be confirmed by the two associations before it can have any force or be legal.

In doctrine the church is Calvinistic, but its preachers are far from being rigid in this particular, being warmly evangelical, and, in general, distinctly cultured. It is a remarkable fact that every Welsh revival, since 1735, has broken out among the Calvinistic Methodists. The ministerial system is quite anomalous. It started in pure itineracy; the pastorate came in very gradually, and is not yet in universal acceptance. The authority of the pulpit of any individual church is in the hands of the deacons; they ask the pastor to supply so many Sundays, filling the remainder with any preacher they choose. The pastor is paid for his pastoral work, and receives his Sunday fee just as a stranger does; his Sundays from home he fills up at the request of deacons of other churches. Deacons and preachers make engagements seven or eight years in advance.

The Calvinistic Methodist Church of Wales is in federation with the United Free Church of Scotland, and the Presbyterian Church of England and of Ireland. It is also a constituent of the Pan-Presbyterian Council or Alliance. In 1925 the body numbered: churches, 1,487; chapels and schools, 1,771; ministers and preachers, 1,156; on probation, 1,630; Sunday school teachers and officers, 24,064; communicants, 189,325. Contributions for various religious purposes (including the ministry), amounted to £499,608. There are foreign missions in Assam (India), and in Brittany. The English branch of the Church has 375 chapels and preaching stations, with 35,669 communicants. All the rest are Welsh. One

of the features of the Welsh Churches is the Sunday school, which is attended by adults as well as children.

**CALVISIUS, SETHUS** (1556-1615), German musician and chronologer, was born at Gorschleben, in Thuringia, on Feb. 21, 1556, and died at Leipzig, where he was director of the school of music, on Nov. 24, 1615. In his *Opus Chronologicum* (Leipzig, 1605, 7th ed. 1685) he expounded a system based on the records of nearly 300 eclipses. He put forward an ingenious proposal for the reform of the calendar in his *Elenchus Calendarii Gregoriani* (Frankfort, 1612). His principal work in music is *Exercitationes musicae* (1600-11).

See K. Benndorf, *Sethus Calvisius als Musiktheoretiker* (1894).

**CALVO, CARLOS** (1824-1906), Argentine publicist and historian, was born at Buenos Aires on Feb. 26, 1824. He devoted himself to the study of the law, and in 1860 he was sent by the Paraguayan Government on a special mission to London and Paris. Remaining in France, he published in 1863 his *Derecho internacional teorico y practico de Europa y America*, in two vols., and at the same time brought out a French version. The book immediately took rank as one of the highest modern authorities on the subject. Señor Calvo's next publications were of a semi-historical character. Between 1862 and 1869 he published in Spanish and French his great collection in 15 vols. of the treaties and other diplomatic acts of the South American republics, and between 1864 and 1875 his *Annales historiques de la révolution de l'Amérique latine*, in five vols. In 1884 he was one of the founders at the Ghent congress of the *Institut de Droit International*. In the following year he was Argentine minister at Berlin, and published his *Dictionnaire du droit international public et privé*, in that city. Calvo died in May 1906 at Paris.

**CALVUS, GAIUS LICINIUS MACER**, Roman orator and poet, was born on May 28, 82 B.C., and died, probably, about the age of 35. His father committed suicide when he was about 16, when prosecuted for extortion by Cicero. He became a very successful advocate, but of the 21 speeches he left behind him we know the names of only five, of which the most famous was the first, against Vatinius, who was defended by Cicero. Calvus was short in stature and vehement in action, and Catullus calls him *salaputium disertum*, the eloquent Jack-in-the-Box. In antiquity he was regarded as an orator and poet of the first rank, but very little of his work has survived. His speeches were on the Attic model, and too polished for universal appeal. His poetry consisted of fugitive pieces, lampoons and erotic verse, very highly praised by his contemporaries, Catullus, Propertius and Ovid.

See Weickert, *De G. Licinio Calvo poeta* (1830); F. Plessis, *Calvus* (1896).

**CALW**, a town of Germany, in the republic of Württemberg, on the Nagold, W.S.W. of Stuttgart. Pop. (1925) 5,681. The name of Calw appears first in 1037. In the middle ages the town was under the dominion of a powerful family of counts, whose possessions finally passed to Württemberg in 1345. In 1634 the town was taken by the Bavarians, and in 1692 by the French. The industries include spinning and weaving, etc., and the making of cigars and soap. It trades in wine. It is a health resort also.

**CALYDON**, an ancient town of Aetolia, according to Pliny,  $7\frac{1}{2}$  Roman m. from the sea, on the river Euenus. It was said to have been founded by Calydon, son of Aetolus; to have been the scene of the hunting, by Meleager and other heroes, of the famous Calydonian boar; the Calydonians are said to have taken part in the Trojan war. In 391 B.C. it was in the possession of the Achaeans. After the battle of Leuctra (371 B.C.) it was restored by Epameinondas to the Aetolians. Augustus removed its inhabitants to Nicopolis, founded to commemorate his victory at Actium (31 B.C.). The walls of Calydon, now the Kastro of Kurtagá on the Euenus, have a circuit of over 2 m., with one large gate and five smaller ones. Large terraces outside the walls probably indicate the temple of Artemis Laphria, whose gold and ivory statue was transferred to Patras.

See W. M. Leake, *Travels in Northern Greece*, i. p. 109, iii. pp. 533 sqq.; W. J. Woodhouse, *Aetolia*, pp. 95 sqq.

**CALYPSO**, in Greek mythology, daughter of Atlas (or Oceanus, or Nereus), a nymph of the mythical island of Ogygia.

She entertained Odysseus (*q.v.*) seven years, but could not overcome his longing for home even by a promise of immortality; at last Hermes was sent by Zeus to bid her release him. In several later (Italo-Greek) stories, she bore Odysseus a son Auson, or Latinus. (Homer, *Odyssey*, i. 50, v. 28, vii. 254.)

**CALYSTEGIA**, a genus of twining plants of the family Convolvulaceae (*q.v.*), commonly known as bindweeds and comprising some 15 or more species, widely distributed in temperate and tropical regions, eight of which are found in California. It differs botanically from *Convolvulus* in that the calyx is subtended by two large bracts which partly enclose the flower. Well-known representatives are the hedge bindweed (*q.v.*); the seaside bindweed or shore morning-glory (*C. Soldanella*), widespread along coasts, including those of the British Isles, California and the Pacific ocean generally; and the Japanese bindweed or California-rose (*C. japonica*), native to eastern Asia, widely grown for ornament, and somewhat naturalized in the eastern United States. By many botanists, especially those of the United States, *Calystegia* is made a part of *Convolvulus* and in the standard American floras and horticultural works the foregoing and other similarly bracted species are described under the last named genus.

**CAM (CÃO), DIOGO** (*fl.* 1480–1486), Portuguese discoverer, the first European known to sight and enter the Congo, and to explore the West African coast between Cape St. Catherine (2° S.) and Cape Cross (21° 50' S.) almost from the equator to Walfish bay. When King John II. of Portugal revived the work of Henry the Navigator, he sent out Cam (about midsummer [?] 1482) to open up the African coast still farther beyond the equator. The mouth of the Congo was now discovered (perhaps in Aug. 1482) and marked by a stone pillar (still existing, but only in fragments) erected on Shark point; the great river was also ascended for a short distance and intercourse was opened with the natives. Cam then coasted down along the present Angola (Portuguese West Africa) and erected a second pillar, probably marking the termination of this voyage, at Cape Santa Maria (the Monte Negro of these first visitors) in 13° 26' S. He certainly returned to Lisbon by the beginning of April 1484, when John II. ennobled him, made him a *cavalleiro* of his household (he was already an *escudeiro* or esquire in the same), and granted him an annuity and a coat of arms (April 8 and 14, 1484). That Cam, on his second voyage of 1485–86, was accompanied by Martin Behaim (as alleged on the latter's Nuremberg globe of 1492) is very doubtful; but we know that the explorer revisited the Congo and erected two more pillars beyond the farthest of his previous voyage, the first at another "Monte Negro" in 15° 41' S., the second at Cape Cross in 21° 50', this last probably marking the end of his progress southward. According to one authority (a legend on the 1489 map of Henricus Martellus Germanus), Cam died off Cape Cross; but João de Barros and others make him return to the Congo, and take thence a native envoy to Portugal. The four pillars set up by Cam on his two voyages have all been discovered *in situ*, and the inscriptions on two of them from Cape Santa Maria and Cape Cross, dated 1482 and 1485 respectively, are still to be read and have been printed; the Cape Cross *padrão* is now at Kiel (replaced on the spot by a granite facsimile); those from the Congo estuary and the more southerly Monte Negro are in the museum of the Lisbon Geographical Society.

João II.*; Garcia de Resende, *Chronica*; Luciano Cordeiro, "Diogo Cão," in *Boletim* of the Lisbon Geog. Soc., 1892; E. G. Ravenstein, "Voyages of Diogo Cão," etc., in *Geog. Jnl.*, vol. xvi. (1900); also *Geog. Jnl.*, xxxi. (1908).

(C. R. B.)

**CAMALDULIANS**, a religious order founded by St. Romuald (also called CAMALDOLESE). Born of a noble family at Ravenna c. 950, he retired at the age of twenty to the Benedictine monastery of S. Apollinare in Classe; but being strongly drawn to the eremitical life, he went to live with a hermit in the neighbourhood of Venice and then again near Ravenna. Here a colony of hermits grew up around him and he became the superior. In this way during the course of his life Romuald formed a great number of colonies throughout central Italy. His chief foundation

was at Camaldoli on the heights of the Tuscan Apennines not far from Arezzo, in a vale snow-covered during half the year. Romuald's idea was to reintroduce into the West the primitive eremitical form of monachism, as practised by the first Egyptian and Syrian monks. Disciples of St. Romuald went on missions to the still heathen parts of Russia, Poland and Prussia, where some of them suffered martyrdom. In his extreme old age St. Romuald with twenty-five of his monks started on a missionary expedition to Hungary, but he was unable to accomplish the journey. He died in 1027. After his death mitigations were gradually introduced into the rule and manner of life; and in the monastery of St. Michael in Murano, Venice, the life became cenobitical. From that time to the present day there have always been both eremitical and cenobitical Camaldolese, the latter approximating to ordinary Benedictine life.

See Max Heimbucher, *Orden und Kongregationen* (1896) i. § 29; art. "Camaldulenser" in Wetzer and Welte, *Kirchenlexikon* (2nd ed.), and Herzog-Hauck, *Realencyklopädie* (3rd ed.); and art. "Camaldolese," *Catholic Encyclopaedia*, vol. iii.

**CAMARGO, MARIE ANNE DE CUPIS DE** (1710–1770), French dancer, of Spanish descent, was born in Brussels on April 15, 1710, the daughter of a violinist and dancing-master. At ten years of age she was given lessons by Mlle. Françoise Prévost (1680–1741), then the first dancer at the Paris Opéra, and at once obtained an engagement as *première danseuse*, first at Brussels and then at Rouen. Under her grandmother's family name of Camargo she made her Paris *début* in 1726, and at once became the vogue. Every new fashion bore her name; her manner of doing her hair was copied by all at court; her shoemaker—she had a tiny foot—made his fortune. She had many titled adorers, whom she nearly ruined by her extravagances, among others Louis de Bourbon, comte de Clermont. At his wish she retired from the stage from 1736 to 1741. In her time she appeared in 78 ballets or operas, always to the delight of the public. She was the first ballet-dancer to shorten the skirt to what afterwards became the regulation length. There is a charming portrait of her by Nicolas Lancret in the Wallace collection, London.

**CAMARGUE**, the thinly-populated Rhone delta, department of Bouches-du-Rhône, France. It is a marshy alluvial plain between the Grand Rhône to the east and the Petit Rhône to the west. Its average elevation is from 6½ to 8 feet. The Camargue has a coast-line some 30m. in length and an area of 290 square miles. About a quarter of this, along the river banks, is fertile and cultivated. The rest is rough pasture for sheep and the local black bulls and white horses, or marsh, stagnant water and salty areas. It is a centre for sea-birds, flamingoes and bustards. The Étang de Vaccarès, the largest of the numerous lagoons, covers about 23 sq.m.; it receives three main drainage canals. Inlets in the protecting sea-dike let in water for the purposes of the lagoon fisheries and salt-pans; and the river water is used for irrigation and for the submersion of vines. Hard winters and scorching summers are the rule; the mistral, blowing from the north and north-west, is the prevailing wind.

Many details of the region are discussed in R. D. Oldham's "Portolan Maps of the Rhône Delta," *Geogr. Journ.* lxx., p. 403 (1925).

**CAMARINA**, an ancient city of Sicily, situated on the S. coast, about 17m. S.E. of Gela (Terranova). It was founded by Syracuse in 598 B.C., but defeated by the mother city in 553 in an attempt to assert its independence. Hippocrates of Gela received its territory from Syracuse and restored the town in 491, but it was destroyed by Gelon in 484 and its population transferred to Syracuse; the Geloans, however, founded it anew in 461. It was abandoned by Dionysius's order in 405, restored by Timoleon in 339 but in 258 was destroyed by the Romans. To the north lay the marsh, formed by the river Hypparis to which the answer of the Delphic oracle referred, *μη κλειει Καράριον*, when the citizens enquired as to the advisability of draining it.

On the site of the ancient city nothing is visible but a small part of the temple of Athena and a few foundations of houses; remains of the harbour and portions of the city wall have been

traced by excavation, and the cemeteries have been carefully explored and have yielded important objects. See B. Pace, *Catania* (Catania, Tirelli, 1927).

**CAMBACÈRES, JEAN JACQUES RÉGIS DE**, DUKE OF PARMA (1753-1824), French statesman, was born at Montpellier on Oct. 18, 1753. In 1792 the newly organized department of Hérault sent him as one of its deputies to the Convention. Cambacères took no decided part in party strife but occupied himself mainly with the legal and legislative work which went on almost without intermission even during the Terror. He had laid down conjointly with Merlin of Douai, the principles on which the legislation of the revolutionary epoch should be codified. At the close of 1794 he also urged the restoration of the surviving Girondins to the Convention, from which they had been driven by the *coup d'état* of May 31, 1793. In the course of the year 1795, as president of the Committee of Public Safety, and as responsible especially for foreign affairs, he helped to bring about peace with Spain. At the dissolution of the Convention Cambacères was one of those on the list of candidates for the Directory, but was not elected. The moderation of his views brought him into opposition to the Directors after the *coup d'état* of Fructidor (Sept. 1797), and for a time he retired into private life. Owing, however, to the influence of Sieyès, he became minister of justice in July 1799. He gave a guarded support to Bonaparte and Sieyès in their enterprise of overthrowing the Directory (*coup d'état* of Brumaire 1799).

After a short interval Cambacères was, by the constitution of Dec. 1799, appointed second consul of France. He undoubtedly helped very materially to ensure to Napoleon the consulship for life (Aug. 1, 1802); but the second consul is known to have disapproved of some of the events which followed, notably the execution of the duc d'Enghien, the rupture with England, and the proclamation of the empire (May 19, 1804). He then became arch-chancellor of the empire and president of the Senate in perpetuity. He also became a prince of the empire and received in 1808 the title duke of Parma. Apart from the important part which he took in helping to co-ordinate and draft the Civil Code, Cambacères did the State good service by seeking to curb the impetuosity of the emperor, and to prevent enterprises so fatal as the intervention in Spanish affairs (1808) and the invasion of Russia (1812) proved to be. In 1815, during the Hundred Days, he took up his duties reluctantly at the bidding of Napoleon; and after the second downfall of his master, he was for a time exiled. A decree May 13, 1818 restored him to his civil rights as a citizen of France; but the last six years of his life he spent in retirement. In demeanour he was quiet, reserved and tactful, but when occasion called for it he proved himself a brilliant orator. He was a celebrated *gourmet*, and his dinners were utilized by Napoleon as a useful adjunct to the arts of statecraft.

See A. Aubriet, *Vie de Cambacères* (2nd ed., 1825).

**CAMBALUC**, the name by which the city on the site of the present Peking in China became known to mediaeval Europe. The word represents the Mongol Khan-Balik, "the city of the Khan," and was often, as by Longfellow, inaccurately spelt Cambalu. A city had long stood on its site, but it did not become the capital of all China until Kublai Khan transferred the capital of the Mongol confederacy from Karakorum up on the Mongolian steppe to Khan-Balik in the conquered lowlands of China. It was not until the Mongol conquests temporarily united western with eastern Asia that mediaeval travellers reached China from Europe and the place-names they took back with them were those employed by the Mongols.

Kublai Khan built a new city, completed in 1267, across a brook from the old city of Yenking and all but the northern third of his city is now occupied by the present "Tartar" city of Peking. Kublai's Palace seems to have stood on the same site as the Imperial Palace of the late Manchu dynasty. According to Marco Polo's description, Cambaluc was laid out on a rectangular plan and had a circuit of 24 miles. Its walls, 50 ft. high and on top 15 ft. broad, were each pierced by three gates, the roadways

connecting them running straight across the city. Cambaluc was not only the capital of the eastern Khanate (which comprised besides China the plateaux and steppes of Tibet, Mongolia and Manchuria) but was also the terminus of the overland trade-route from western Asia and so from Europe across high Central Asia, just as Zaiton on the south-east China coast was the terminus of the sea-route from India by way of the Spice Islands. The Polos reached China by the first route and returned by the second. The population participating in this overland commerce seems to have lived outside the walls of Cambaluc and in Marco Polo's time, the last quarter of the 13th century, the population outside was greater than that within. The name Cambaluc refers essentially to the city of the Mongol period and the succeeding Chinese Ming dynasty re-named the city Peking, the northern capital, as distinct from Nanking, the southern capital. (See also CATHAY and PEKING.)

**CAMBAY**, a native state (Kaira agency) of India, in the Gujarat division of Bombay. It has an area of 350 square miles. Pop. (1921) 71,762. The tribute is £1,337. Cambay is entirely an alluvial plain. As a separate state it dates only from about 1730, the time of the dismemberment of the Mogul empire. The present chiefs are descended from Momin Khan II., the last of the governors of Gujarat, who made himself governor of Cambay in 1742. Wheat and cotton are the chief crops. The nawab being a minor, the state was under British administration in 1928.

The town of Cambay had a population in 1921 of 27,303. It is supposed to be the *Camanes* of Ptolemy and was formerly the seat of an extensive trade and textile manufactures; but, owing principally to the rise of Surat and the silting up of the harbour, its commerce fell away, and the town became unimportant. The spring tides rise upwards of 30 ft. The town is celebrated for its manufacture of agate and carnelian ornaments, of reputation principally in China. There is a cotton mill. Many houses are built of stone (which indicates the former wealth of the city, as the material had to be brought from a distance); and remains of a brick wall, 3 m. in circumference, which formerly surrounded the town, enclose four large reservoirs and three bazaars. To the south-east there are extensive ruins of subterranean temples and other buildings half-buried in the sand by which the ancient town was overwhelmed. These temples belong to the Jains, and contain two massive statues of their deities. In 1780 Cambay was taken by the army of General Goddard, was restored to the Mahrattas in 1783, and was afterwards ceded to the British by the Peshwa under the treaty of 1803. It is connected through Petlad with the Bombay, Baroda and Central India railway.

**CAMBAY, GULF OF**, a trumpet-shaped inlet on the west coast of India, narrowing northwards between Kathiawar peninsula and Gujarat. Its shape and orientation in relation to the south-west monsoon winds explain its very high tides and the velocity with which they enter. But it shallows rapidly; the silt of flood torrents entering its head contributes to progressive deterioration, and shoals and sandbanks are everywhere treacherous. Broach is one of the oldest Indian ports; Surat is particularly identified with the rise of direct European contacts with India, and Bhaunagar is a noteworthy entry for Kathiawar, but the importance of the gulf ports is now only local.

**CAMBER**, in engineering, the upward convexity given to a beam or girder to allow for the load. If the camber is properly calculated, the cambered member becomes straight when loaded. The word camber is from Fr. *cambrer*, to arch, and is also used in other connections; e.g., the curve given to a roadway and the curvature of the wing of an aeroplane in imitation of the camber of a bird's wing.

In architecture camber is a slight upward curve to correct the illusion of sagging which a straight unsupported line presents.

**CAMBERT, ROBERT** (1628-1677), French musician, was born in Paris in 1628 and is remembered as one of the first composers of opera in France, at first in conjunction with the Abbé Pierre Perrin and afterwards on his own account. In 1669 Perrin received a patent for the founding of the *Académie Nationale de musique*, the germ of the Grand Opéra, and Cambert had a share in the administration until both he and Perrin were discarded in

the interests of Lulli. Displeased at his subsequent neglect, and jealous of the favour shown to Lulli, who was musical superintendent to the king, he went in 1673 to London, where soon after his arrival he is said to have been appointed master of the band to Charles II. He is supposed to have killed himself—according to another account he was murdered—in London in 1677.

**CAMBERWELL**, a southern metropolitan borough of London, England, bounded north by Southwark and Bermondsey, east by Deptford and Lewisham, west by Lambeth and extending south to the boundary of the county of London. Pop. (1931) 251,373. Area, 4,480 acres. It appears in Domesday, but the derivation of the name is unknown. It includes the districts of Peckham and Nunhead, and Dulwich (*q.v.*) with its park, picture-gallery and schools. Camberwell is mainly residential, and there are many good houses in Dulwich and southward towards the high ground of Sydenham. Dulwich Park (72 acres) and Peckham Rye Common and Park (113 acres) are the largest of several public grounds, and Camberwell Green was once celebrated for its fairs. The parliamentary borough of Camberwell has four divisions, North, North-West, Peckham and Dulwich, each returning one member.

**CAMBIASI, LUCA** (1527-1585), Genoese painter, familiarly known as Lucchetto da Genova (his surname is written also Cambiaso or Cangiagio), was born at Moneglia in the Genoese state, the son of a painter named Giovanni Cambiasi. At the age of 15 he painted, with his father, some subjects from Ovid's *Metamorphoses* on the front of a house in Genoa, and afterwards, in conjunction with Marcantonio Calvi, a ceiling showing great daring of execution in the Palazzo Doria. Lucchetto's best artistic period lasted for twelve years after his first successes. In 1583 he accepted an invitation from Philip II. to continue in the Escorial a series of frescoes which had been begun by his friend Giambattista Castello. He died in the Escorial in the second year of his sojourn. Cambiasi painted sometimes with a brush in each hand, and with a certainty equalling or transcending that even of Tintoret. He made a vast number of drawings, and was also something of a sculptor, executing in this branch of art a figure of Faith. His son Orazio became likewise a painter, studying under Lucchetto.

The best works of Cambiasi are to be seen in Genoa. In the church of S. Giorgio, the martyrdom of that saint; in the Palazzo Imperiali Terralba, a Genoese suburb, a fresco of the "Rape of the Sabines"; in S. Maria da Carignano, a "Pietà" containing his own portrait and (according to tradition) that of his sister-in-law, whom he loved, and who after the death of his wife, had taken charge of his household. In the Escorial he executed several pictures; one is a Paradise on the vaulting of the church, with a multitude of figures. For this picture he received 12,000 ducats, probably the largest sum that had, up to that time, ever been given for a single work.

**CAMBIST**, a shortened form of *cambista*, which is Italian for money-changer. A cambist is one who deals in foreign bills of exchange and bank notes. The term is also applied to conversion tables of foreign money, weights, and measures. (*See EXCHANGES, FOREIGN.*)

**CAMBODIA**, a protectorate within French Indo-China. It is bounded north by Siam and Laos, east by Annam, south-east and south by Cochinchina, south-west by the Gulf of Siam, and west by Siam. Its area is 65,000 sq.m.; its population (1926) 2,402,583, three-quarters Cambodian, the rest Chinese, Annamese, Chams, etc. Cambodia has more varied surface features than Cochinchina. The Cardamome mountains in the west reach 4,900 ft., and their granite buttresses extend north-eastwards to the lakes, with forests on their steep sides, while the calcareous Elephant mountains extend from them southwards to the Gulf of Siam. To the north the sandstone terraces of the Dangrek mountains fall abruptly to the Cambodian plain, the old Mekong (*q.v.*) delta. The Tonlé-Sap depression is a striking feature with the smaller and the larger lake, remnants of an old sea-gulf. It is fed by several streams and links with the Mekong by a channel at Pnom-Penh, through which it receives Mekong flood waters. In June the waters of the Mekong rise to a height of 40 to 45 ft. and flow through the

Bras du Lac towards the lake, which then covers an area of 770 sq.m. and, like the river, inundates the marshes, forests and cultivated lands on its borders. During the dry season the current reverses, the lake shrinks to an area of 100 sq.m., and its depth falls from 45-48 ft. to a maximum of 5 ft. Tonlé-Sap probably represents the chief wealth of Cambodia. It supports a fishing population of over 30,000; the fish, taken in large nets at the end of the inundation, are either dried or fermented for the production of *nuoc-mam* sauce. West of the large lake, around Battam Bang, is the largest Cambodian rice-area. The mountainous region east of the Mekong is traversed by affluents of the Mekong, the Se-khong and the Tonlé-srepok, which unite to flow into the Mekong at Stungtreng. Small islands, with a fishing population, fringe the west coast.

**Climate, Fauna and Flora.**—From mid-October to mid-April the north-east monsoon gives dry weather, the rainy season (mid-April to mid-October) is due to the south-west monsoon. At Pnom-Penh there is little variation of temperature (average 81°)—January giving 79°, and April, the warmest month, 84°. Wild animals include the elephant, which is also domesticated, the rhinoceros, buffalo and some species of wild ox; also the tiger, panther, leopard and honey-bear. The crocodile is found in the Mekong, and there are many reptiles, some venomous. The buffalo is the chief draught animal. Swine are reared in large numbers. Nux vomica, gamboge, caoutchouc, cardamoms, teak, the lac-tree, and valuable woods and gums are among the natural products.

**People.**—The Cambodians are more closely akin to the Siamese than to the Annamese. The race is probably the result of a fusion of aborigines of Indo-China with the Aryan and Mongolian invaders of the country. The men are taller and more muscular than the Siamese and Annamese, while the women are small and inclined to stoutness. The face is flat and wide, the nose short, the mouth large and the eyes only slightly oblique; the skin is dark brown, the hair black. Both sexes wear the langouti or loincloth, which the men supplement with a short jacket, the women with a long scarf draped round the figure, or a long clinging robe. The wife enjoys a respected position and divorce may be demanded by either party. Polygamy is almost confined to the richer classes. The Cambodians make good hunters and woodsmen; many live on the borders of the Mekong and the great lake, in huts built upon piles or floating rafts. The religion is Buddhism, and in-

FROM KROM, "INLEIDING TOT DE HINDOE," (N.Y. MARTINUS NIJHOFF'S BOEKHANDEL)  
SECTION OF BARABUDUR TEMPLE, JAVA, SHOWING ARRANGEMENT OF GALLERIES WITH SHRINES AND STUPAS. THE GALLERIES CONTAIN A SERIES OF RELIEFS REPRESENTING BUDDHIST TRADITIONS

volves great respect towards the dead; the worship of spirits or local genii is also widespread, and Brahmanism is still maintained at the court. Numerous monks or *bonzes* live by alms, and in return teach the young to read, and superintend coronations, marriages, funerals, and the other ceremonials. As in the rest of Indo-China, there is no hereditary nobility, but superior castes founded on blood-relationship, as well as the mandarins, who form a class by themselves, are exempt from tax or forced service. The mandarins are nominated by the king and their children have a position at court, and are generally chosen to fill the vacant posts in the administration. Under the native régime the common people attached themselves to one or other of the mandarins, who in

return granted them the protection of his influence. Under French rule, local government of the Annamese type is supplanting this feudal system. Slavery was abolished by royal ordinance (1897).

Cambodian idiom is like some aboriginal dialects of south Indo-China; it is agglutinate and rich in vowel-sounds. The king's language and the royal writing, and also religious words are, however, apparently of Aryan origin and akin to Pali. Cambodian writing is syllabic and complicated.

**Industry, Agriculture and Commerce.**—Iron, worked by the tribe of the Kouis, is found in the mountainous region. The Cambodians show skill in working gold and silver; silk-cultivation is extending, and Pnom-Penh has a sericulture school; we may also name the cultivation of rice and, in a minor degree, that of tobacco, coffee, cotton, pepper, indigo, maize, tea and sugar. Factories near Pnom-Penh shell cotton-seeds. The fisheries of the great lakes produce 100,000 tons per annum and make fishing of great economic importance.

Trade, largely in Chinese hands, is carried on chiefly through Saigon in Cochinchina, Kampot, the only port of Cambodia, being accessible solely to coasting vessels. Pnom-Penh (*q.v.*) communicates regularly by the steamers of the "Messageries Fluviales" by way of the Mekong with Saigon. About 90% of the exports are accounted for and are by river. In 1925 they included 26,470,039 kg. of fish and fish products, 3,029 kg. of silk, 5,566 tons of rice, 1,189 tons of cotton and 114,565 tons of paddy.

**Administration.**—The king (*rājā*) either nominates his successor, in which case he sometimes abdicates in his favour, or else is elected by the five chief mandarins from among the Brahmins, members of the royal family within the fifth degree. The king is advised by a council of five ministers, the superior mandarins; and there are about 50 provinces administered by mandarins. France has a resident superior, who presides over the ministerial council and is the real ruler of the country, and residents exercising supervision in districts. In each residential district there is a council of natives, presided over by the resident, which deliberates on questions affecting the district. The resident superior is assisted by the protectorate council, consisting of heads of French administrative departments (chief of the judicial service, of public works, etc.) and one native "notable," and the royal orders must receive its sanction before they can be executed. Control of foreign policy, public works, customs and the exchequer are in French hands, while management of police, collection of direct taxes and administration of justice between natives remain with the native Government. A French tribunal alone is competent to settle disputes where one of the parties is not a native.

The French are developing a network of communications, and the production of cotton and silk, as well as the fisheries of the lakes.

The chief sources of revenue are direct taxes, including poll-tax and taxes on the products of the soil, which amounted to 8,215,575 piastres in 1925—3.42 piastres per head. (*See* INDO-CHINA, FRENCH.)

### ARCHAEOLOGY

The spread of Indian culture to this area, after the beginning of the Christian era, left no monuments of the first centuries, probably because at that time wood was the only building material known, but from the sixth and seventh centuries onwards temples and stone and bronze images are found. In the older forms the direct influence of the Indian tradition is perceptible. The monuments are small with great sobriety of sculpture. In the more recent period the native elements of the district in question assert themselves and the ornamentation becomes richer and more elaborate. Vast elaborately constructed groups of temple buildings arose in Java in the second half of the first period, while in Cambodia they belong to the more recent period. Finally, due principally to political circumstances, a period of degeneration set in, in Cambodia after the 12th century, in Champa after the 11th and in Java after the 14th century.

In the valley of the Mekong, the district around the great lake and the adjoining hills, the name of the oldest established kingdom, Fu-nan, gives place in the Chinese documents after the sixth century, to that of Chen-La, without evidence of the connection

between the ancient kingdom and the two simultaneous Chen-La states, the northern and the southern. The art of the sixth to the eighth century may be termed primitive Khmer. In the course of the eighth century the northern Chen-La gained predominance, and from the ninth century union with the Khmers was an established fact. In regard to art the first part of this century is a

blank, followed by a transition period, named after the reigning prince Indravarman, which has certain common features with the primitive style, but is in general nearly related to the classical Khmer art of the following centuries. Classical art flourished from the 10th to the 12th century, reaching its highest point in the temple of Angkor Wat. After this degeneration rapidly set in.

### The Primitive Khmer Style.

—This yields usually small, solitary temples (*prāsāt*) rectangular or square constructed in brick. Horizontal lines predominate, the profiling is weak and the mouldings are furnished with niche-shaped antefixes, with human heads as ornamentation. The external roof, built in storeys, does not correspond to the vaultings of the interior, because this style of building arose through the adaptation in stone of a style already using lighter materials. Probably a survival of the pre-Khmer style is to be found in the miniature buildings carved in relief, forming the decoration of the frontages and the space above the entrance, in the latter case enclosed in a wide arch. The entrance itself, flanked by round pillars, is covered by a lintel, a favourite theme for which is a depressed arch, often set with medallions, the extremities springing from the open mouths of *makaras* (sea-elephants).

FROM DE LAJOUERGIE, "INVENTAIRE DEScriptif DES MONUMENTS DU CAMBODGE," BY COURTESY OF L'ÉCOLE FRANÇAISE D'EXTREME ORIENT

LONGITUDINAL SECTIONS THROUGH CAMBODIAN TEMPLES. THESE ARE BUILT OF BRICK AND VAULTED. THE LOWER TEMPLE HAS A PORCH WITHIN THE ENTRANCE

In this primitive art two styles, a simpler and a more complicated, are recognizable. The latter is richer and lighter in decoration, the building is raised upon a considerable base, having projections on all four sides, one of which contains the entrance, the others bearing niches or blind doors. The roof, which is the first style, is constructed of many storeys, each of small height, is in the latter a few stories of great height, which lend to the whole a slender appearance. The first style has been regarded as being Hindu, and therefore in contrast to the later Khmer art.

The most important remains are those of Sambor Prei Kuk, to the east of the great lake, some forty buildings, divided into different groups of both types. The stone cell of Asram Maha Rosei on the lower Mekong represents the older type and the lofty temple of Bayang the later one. In the lake district the simple Trapan Kuk contrasts with Damrei Krap and the group of Pra Srei; while on the upper Mekong at Han Cei both styles are found. At Boran is preserved the only complete example of a temple with two chambers. The sculpture of this period combines severity of design with delicacy of modelling; of which the images of Phnom Da and the Harihara of Andet are striking examples.

**Indravarman Art.**—In common with the primitive style the buildings are solitary, usually in brick, preferably, however, in the square ground plan. The form of the arch above the entrance persists, and the pillars flanking the entrance, though now almost always octagonal in place of round, are treated in the same spirit,

the makara motive on both sides of the lintel being still frequently found.

The representation of buildings upon the façade has disappeared and given place to sculptured panels; mouldings and decoration have taken different forms, the technique is changed, the lintel has lost its architectural character and has become merely an ornament. In everything a tentative search for new forms is felt.

The group of sacred buildings at Roluoh, south east of Angkor, consisting of the shrines of Prah Ko, Bakong and Lolei, is characteristic of the Indravarman style. The first consists of two rows of three temples with a few outbuildings, contained within a double wall; Bakong is a tall pyramidal construction of six stories in stone, with two brick smaller temples on either side; Lolei is formed of four temples upon a vast terrace. With these, though of a somewhat later date, may be grouped Pre Rup, five temples raised upon a terrace, with twelve upon a lower level and a conglomeration of terraces, gateways and minor buildings; the (eastern) Mebon, also comprising five central temples, but with rather different surroundings; and Baksei Camkrong set alone upon a foundation raised in terraces. At Içvarapura, the present Bantay Srei, is a main temple between two others, in which the proportions of the stone buildings are small. They are conspicuous for the delicacy of their execution. This temple is typical of the Indravarman style in a number of particulars, although it was only built in the 14th century in what was then a very archaic style, to replace a 10th century sanctuary. The principal image is the representation of Śiva with Umā, almost naked, carved in bold lines, without ornamentation except for the head dress.

The oldest productions of the *classical style* are usually attributed to the ninth century (King Yaçovarman, 889-910). Certain characteristics are shared with the Indravarman style, which also produced groups of buildings with gateways and minor constructions, divine figures, often heavenly nymphs in niches, forming the principal decoration of the panels on the façade. The entrance, between octagonal pillars, is covered by a lintel, ornamented by garlands extending from the centre-piece, this centre-piece being frequently formed by the head of a monster. The *makaras* are replaced by *nagas* (snakes) which coil around the pointed-arch above the lintel, and other projecting parts and rear their heads on both sides; also the profiling is more animated.

The principal buildings, now almost invariably of stone, are connected by a more or less consecutive system of galleries. Great projections on each side transform the square into a cruciform plan. The layers of the roof repeat this form, succeeding each other in such a way that the whole roof, beneath the great lotus flower by which it is crowned, acquires an elongated cone shape, giving it the appearance of a tower.

The centre of this classical art is the capital city of Angkor Thom, the building of which is supposed to have been begun at the end of the 9th century. At Banteai Chma, in the north west, are still older remains of an ancient stronghold of the 9th century, showing even then the typical construction of a classical sanctuary. The temples of which the centre one has a portico, are combined and surrounded by a square gallery with four gateways; in front more passages and galleries join on, connected by side galleries; the whole, with other buildings at the side and back, is surrounded by another gallery, outside which again lie ponds and entrances with balustrades, the latter formed of huge snakes. The mountain of Kulen and perhaps Prah Khan, yield further examples of the older classical style; in the latter group there are twelve minor temples, excluding the outbuildings.

Angkor Thom itself, the ancient Yaçodharapura, is a square, surrounded by wall and moat, each side of which is three kilometers in extent. There are five gateways, from which roads with snake-balustrades lead to the centre of the city. In this centre stands the state temple Bayon. The chief building is surrounded by two galleries provided with portals and turrets and decorated with reliefs. These towers and the gates are cut in the form of four huge human faces, presumably representations of Śiva. The central tower, outside which a ring of small chapels are built, is provided with projections. In front there is a network of corridors and side passages; the inner chamber contained Śiva's Lingga,

while in the chapels both Hindu and Buddhist sacred images are found. The latter, however, were probably introduced at a later date. North of Bayon lie the remains of the palace, in which the royal temple Phimeanakes still stands. Gallery and shrine here arise above three steep terraces. In front of the building runs a great terrace of honour ornamented with reliefs (elephants and others). All this is believed to belong to the most ancient plan

| B. Gallery with reliefs   | G. Inner Court                           |
| C. Libraries              | H. Corner Towers                         |
| D. Galleries of Vestibule | I. Central Tower, with sanctuary of Śiva |
| E. Outer Court            |  |

of the city. Ta Prohm, to the east, dates from the same time, having a particularly intricate arrangement of projections against the inner gallery, large gateways and ponds. The neighbouring Banteai Kedei, attached to a great pond, while adhering to the leading principles, shows a very mixed ground plan.

The group of Koh Ker, the remains of a new capital city, in the classical style but much simpler in construction, belongs to the second quarter of the tenth century. In the capital itself, Baphuon dates from this period, and is reared up high upon the topmost of three steep terraces, each of which is surrounded by a gallery and reached by a triple balustraded way. Ta Keo, just outside the city, is of the 11th century, with five towers on a high terrace, four at the corners and one in the middle. These great institutions are mostly Sivaitic; Buddhism is rather less conspicuous, although a great veneration for the Bodhisattva Lokeśvara is apparent everywhere. The same reign (Sūryavarman I. 1002-1050) saw Prah Vihear arise, on a high forepost of the Dangrek, a temple now ruinous with gallery porticos and a long approach with steps, portals and terraces. In Phnom Chiso(r) the same features can be recognized, the 200 sanctuaries of which are constructed of the old brick material.

The culmination of classical art is reached in Angkor Vat, the magnificent Sivaitic sanctuary raised by Sūryavarman II. (1112-

1152) to the south of the capital. The temple court, surrounded by a broad moat, contains two square cloisters rising one above the other and surrounding the central pile of four corner turrets and a central tower connected by galleries, with an elaborate approach. The celebrated reliefs in the first gallery represent scenes from the heroic epics, the contemporary royal court, priesthood and army.

**Champa.**—The history of Champa art, taken as a whole, shows a gradual process of degeneration, following the expulsion of the Chams from Annam, by the Annamites from Tonkin. The removal of the capital to Chaban in the south about A.D. 1000, divides the older (primary) period from the more recent (secondary). When stone came into favour for temple buildings (*kalan*) and replaced the lighter material—in Champa they have always gone on building in brick—we find, beside the small temples of the delicate form of the primitive art, another kind of building of a much more massive and heavy construction, to which the name of cubic art has been given. In the 10th century they fuse and form a hybrid style, though the pure primitive style still persists, and at the beginning of the secondary period, produces the so-called classical art, which follows the forms of the older style. In several buildings, an alteration in the form of the roofing leads to the pyramidal style, which survived to the 14th century. Classical art maintained itself up to the beginning of the 12th century. It then shows a rapid decline and after the fall of Chaban in 1471 is completely degenerate, although up to the 17th century it still produced buildings.

In sculpture, the oldest pieces are the best, some obviously dating from before the oldest monuments, e.g., those from Tra-kieu. The primitive shrines are small square edifices, with a separate vestibule in front and projections for blind doors on the other sides. The plan of the temple building is repeated in the stories of the roof, which recede and leave space for small corner towers, the whole surmounted by an apex usually octagonal. The façades are decorated with slender pillars and floral or foliated scrolls. Divine nymphs, at the corners of the cornice with projecting motives at the foot of the buildings, form a typical characteristic of Cham art. The cubic style is much more artificial and conventional; the layers of the roof recede less and the corner towers disappear. The pilasters are broad and heavy. Mi-Son, south of Tourane contains the remains of some sixty small temples, dedicated to Siva; which exemplify the whole development of the Cham style from the 7th century onwards. In the sculpture of the divine figures, the gradual deterioration is perceptible. In Po Nagar near Nhatrang, beside the style of the first period, pyramidal forms are found; the primitive style marks the temples of Khuong My and Binh Lam. As specimens of cubic style, Po Dam and Hoa Lai and the group of Dong Duong, south of Mi-Son, are the most important.

The remains of the second period are necessarily in the south. In the classical style of the 11th century, descended from the primitive way everything that demands special skill is eliminated; decorative sculpture is replaced by a repetition of mouldings and edgings, terra-cotta ornaments take the place of sculpture; the roofs become higher and more clumsy, as at Binh Dinh, in the so-called Towers of Silver, Copper and Gold. The increase in number and the decrease in size of the stories of the roof which at the same time are less overlapping, lead to the pyramidal roof, running up in gentle curves, of Hung Thanh and Chanh Lo. An attempt to return to the old style at the end of the 11th century forms the derivative style, as at Chien Dang, Klaung Garai and Po Rome.

## HISTORY

The name *Kambuja*, whence the European form Cambodia, is derived from the Hindu *Kambu*, the name of the mythical founder of the Khmer race. Some centuries before the Christian era, immigrants from the east coast of India began to exert a powerful influence over Cambodia, introducing Brahminism and the Sanskrit language. This Hinduizing process became more marked about the 5th century A.D., when, under S'rutavarman, the Khmers as a nation rose into prominence. At the end of the 7th century the dynasty of S'rutavarman ceased to rule over the whole of Cambodia, which during the next century was ruled over by two sovereigns. About the beginning of the 9th century, with Jayavarman III., there began a dynasty which embraced the zenith of Khmer greatness. The royal city of Angkor-Thom (see ANGKOR) was completed under Yasovarman about A.D. 900. In the 10th century Buddhism, which had existed for centuries in Cambodia, began to become powerful and to rival Brahminism, the official religion. The construction of the temple of Angkor Vat dates probably from the first half of the 12th century. The conquest of the rival kingdom of Champa, which embraced modern Cochinchina and southern Annam, and in the later 15th century was absorbed by Annam, may probably be placed at the end of the 12th century in the reign of Jayavarman VIII., the last of the great kings. In the later 13th century the liberation of the Thais or inhabitants of Siam from the yoke of the Khmers, to whom they had for long been subject, and the expulsion of the now declining race from the basin of the Menam began. The royal chronicles of Cambodia, the historical veracity of which has often to be questioned, begin about the middle of the 14th century, at which period the Thais assumed the offensive. These aggressions were continued in the 15th century, in the course of which the capital was finally abandoned by the Khmer kings. At the end of the 16th century, Lovek, which had succeeded Angkor-Thom as capital, was itself abandoned to the conquerors. During that century, the Portuguese had established some influence in the country, whither they were followed by the Dutch, but after the middle of the 17th century, Europeans counted for little in Cambodia till the arrival of the French. At the beginning of the 17th century the Nguyen, rulers of southern Annam, began to encroach on the territory of Cochinchina, and in the course of that and the 18th century, Cambodia, governed by two kings supported respectively by Siam and Annam, became a field for the conflicts of its two powerful neighbours. At the end of the 18th century the provinces of Battambang and Siem-reap were annexed by Siam. In 1863, in order to counteract Siamese influence there, Doudart de Lagrée was sent by Admiral la Grandière to the court, and as a result of his efforts King Norodom placed Cambodia under the protection of France, removing his capital to Pnom-Penh in 1866. In 1867 a treaty between France and Siam, was signed, whereby Siam renounced its right to tribute and recognized the French protectorate over Cambodia in return for the provinces of Battambang and Angkor, and the Laos territory as far as the Mekong. In 1884 another treaty was signed by the king, confirming and extending French influence, and reducing the royal authority to a shadow. In 1904 the territory of Cambodia was increased by the addition to it of the Siamese provinces of Melupré and Bassac, and the maritime district of Krat, the latter of which, together with the province of Dansai, was in 1907 exchanged for the provinces of Battambang, Siem-

reap and Sisophon. By the same treaty France renounced its sphere of influence on the right bank of the Mekong. In 1904 King Norodom was succeeded by his brother Sisowath, the present king. Under the French the country has rapidly developed, but there is still a shortage of labour. The opening up of the interior is still rapidly proceeding. The historical monuments of the country make it one of the most important archaeological grounds of Asia.

**CAMBON, PIERRE JOSEPH** (1756-1820), French revolutionary and financier, was born at Montpellier. As a member of the legislative assembly, he quickly attracted public attention by his able and sagacious speeches. An opponent of Marat, Danton and Dumouriez, Cambon nevertheless voted in favour of Louis XVI.'s execution. He opposed the creation of the Revolutionary Tribunal, and he incurred Robespierre's hatred by his outspoken criticism of his actions no less than by his intervention in favour of the Girondists on June 2, 1793. Cambon gave his valuable support to the Mountain, and it was due to his initiative and financial acumen that the *assignats* appreciated in value. Accused by Robespierre of reactionary and aristocratic leanings, Cambon replied so vehemently and effectively that his speech sounded the knell for Robespierre's own downfall. Under the Thermidor Cambon was violently attacked as a supporter of the Mountain and was accused of malversation. In April 1795 he was excluded from the committee of finance, and he soon afterwards sought safety from Tallien's attacks in flight to Switzerland. The amnesty of the 4th Brumaire enabled him to return to his estate at Terral, near Montpellier, where he lived in seclusion throughout the entire Napoleonic era. After Napoleon's downfall, and despite his advocacy of a Bourbon restoration, Cambon was exiled as a regicide. He retired to Belgium and died near Brussels on Feb. 15, 1820.

BIBLIOGRAPHY.—F. Bornard, *Cambon et la Révolution Française* (1905); R. Arnaud, *Cambon* (1926).

**CAMBON, PIERRE PAUL** (1843-1924), French diplomatist, was born on Jan. 20, 1843, and educated at the Lycée Louis-le-Grand and the École de Droit. He was called to the Parisian bar, and became private secretary to Jules Ferry during the Commune. Thiers subsequently appointed him to administrative posts in the Alpes-Maritimes and at Marseilles. Later he became prefect of Lille. In 1882 he was appointed resident in Tunis, where he displayed his rare diplomatic talent. Four years later he was appointed ambassador to Madrid, and in 1890 was transferred to Constantinople, where he had an opportunity of watching German diplomacy at work in the Near East. In 1898 he became French ambassador in London immediately after the Fashoda incident had embittered Franco-British relations. Cambon at once set himself the task of improving those relations, and so successful was he that in 1904 he signed with Lansdowne the Anglo-French Agreement. He was very largely responsible for the promotion of the Anglo-Russian Agreement of 1907. In that year his brother, M. Jules Cambon, became French ambassador in Berlin, and thenceforth the two brothers worked in close accord to frustrate the designs of the military party in Germany. A believer in the doctrine expressed in the old French proverb "Tout vient à temps à qui sait attendre," Cambon pursued his policy of strengthening Franco-British relations with quiet skill. The culmination of his long years of work was reached in November 1912 with the exchange with Sir Edward Grey of the now famous letters regarding a naval and military co-operation between France and Great Britain in the possible event of war. Despite some anxious moments in the early days of Aug. 1914, Cambon never wavered in his belief in Great Britain; and his participation in the war on the side of France fittingly crowned his life-work. During the war he laboured unceasingly to smooth away difficulties and allay irritations between the Allied commands, but when the peace had been signed at Versailles Cambon felt that the hour of his retirement had come. After 22 years of unremitting service to the interests of France and Great Britain,

he left London in 1920 amid manifestations of regret rarely displayed to the ambassador of a foreign power. In 1903 he had been created G.C.V.O., and in 1917 the King accorded him the unusual distinction of the Grand Cross of the Bath. He died in Paris on May 29, 1924.

His brother, **JULES MARTIN CAMBON** (1845- ), was called to the bar in 1866, served in the Franco-Prussian War and entered the civil service in 1871. He was prefect of the department of Nord (1882) and of the Rhone (1887-91), and in 1891 became governor-general of Algeria (see Guyot, *L'oeuvre de M. Jules Cambon*, Paris, 1897), where he had served in a minor position in 1874. He was nominated French ambassador at Washington in 1897, and in that capacity negotiated the preliminaries of peace on behalf of the Spanish Government after the war with the United States. He was transferred in 1902 to Madrid, and in 1907 to Berlin; in 1915 he became secretary to the Ministry of Foreign Affairs. He wrote the article SECURITY for this *Encyclopædia*.

(I. F. D. M.)

**CAMBORNE**, a market town of Cornwall, England, 13m. W.S.W. of Truro, on the G.W.R. Pop. of urban district (1931) 14,157. It lies on the northward slope of the central elevation of the county, among numerous tin and copper mines. Mining, metal-working, stone-quarrying and the making of chemicals are the main industries. The parish church of St. Martin contains an ancient stone altar bearing a Latin inscription. There are science and art and mining schools, and practical mining is taught in South Condurrow mine. It was developed from classes initiated in 1859 by the Miners' Association. Camborne (*Cambron, Camron*) formed part of the large manor of Tehidy, held at Domesday by the earl of Mortain and subsequently by the Dunstanville and Basset families. In the early 18th century copper and tin began to be worked vigorously at Dolcoath: in 1788 ore worth £2,000,000 and in 1882 ore worth £5,500,000 was produced. It was the scene of the scientific labours of Richard Trevithick (1771-1833), the engineer, and of William Bickford, the inventor of the safety-fuze.

**CAMBRAI**, a town of northern France, the seat of an archbishop and capital of an arrondissement in the department of Nord, 37 m. S.S.E., of Lille on the main line of the Northern railway. Pop. (1926) 24,854. Cambrai is situated on the right bank of the canalized Schelde, arms of which traverse the west of the town. Formerly strongly fortified, the ramparts had given way before the war of 1914-18, in which Cambrai figured prominently and was badly damaged, to handsome boulevards.

Cambrai is the ancient Nervian town of *Camaracum*, mentioned in the Antonine Itinerary. In the 5th century it was the capital of the Frankish king Raguacharius. Fortified by Charlemagne, it was captured and pillaged by the Normans in 870, and unsuccessfully besieged by the Hungarians in 953. During the 10th, 11th and 12th centuries it was the scene of frequent hostilities between the bishop and the citizens; but the latter ultimately effected their independence. In 1478 Louis XI., who had obtained the town on the death of Charles the Bold, handed it over to the emperor, and in the 16th century Charles V. built a strong citadel, for the erection of which the castles of Cavillers and Escaudoeuvres were demolished. From that date to the peace of Nijmegen, 1678, which assigned it to France, it frequently changed hands by capture or treaty. The League of Cambrai is the name given to the alliance of Pope Julius II., Louis XII., Maximilian I. and Ferdinand the Catholic against the Venetians in 1508; and the peace of Cambrai (the Ladies' Peace) was concluded in the town in 1529 by Louise of Savoy, mother of Francis I., and Margaret of Austria, aunt of Charles V., in the names of these monarchs. The bishopric of Cambrai, dating from the 5th century, was raised in 1559 to the rank of an archbishopric which continued till the Revolution and has since been restored. The bishops received the title of count from the emperor Henry I. (919-936), and in 1510 were raised to the dignity of dukes, their territory including the town itself and its territory, called Cambrésis. In the war of 1914-18, Cambrai was occupied by the Germans from August 26, 1914, to October 8, 1918. When they retired they left the town heavily mined, and the central portion was wrecked. (See also CAMBRAI, BATTLE OF.)

The former cathedral of Cambrai was destroyed after the Revolution. The present cathedral of Notre-Dame is a church of the 19th century built on the site of the old abbey church of St. Sulpice. It was severely damaged in 1918, but the façade is intact. Among other monuments it contains that of Fénelon, archbishop from 1695 to 1715. The church of St. Géry (18th century) contains, among other works of art, a marble Renaissance rood-screen. The Place d'Armes, a large square in the centre of the town, is bordered on the north by the *hôtel de ville* (1863). The Tour St. Martin is an old church-tower of the 15th and 18th centuries transformed into a belfry. The triple stone portal, which gave entrance to the former archiepiscopal palace, is a work of the Renaissance period.

Cambrai has a sub-prefect, tribunals of first instance and of commerce, a board of trade-arbitrators and a chamber of commerce. There is a museum of antiquities and objects of art. Prior to 1914 it was a prosperous industrial town, its chief industry being the weaving of muslin (*batiste*) and other fine fabrics (see CAMBRIC); wool-spinning and weaving, bleaching and dyeing were also carried on. The town has now regained its pre-war position; there are large beet-sugar works, and trade is in coal, cattle and grain.

**CAMBRAI, BATTLE OF.** In the history of the World War of 1914-18 this battle, fought in Nov.-Dec. 1917, stands out as a landmark in the history of warfare. On Nov. 20, 1917, the British 3rd Army launched an attack, based on a new method, with an initial success so striking that on the morrow the bells of London were rung in joyous acclaim of the "victory." Little more than a week later, on Nov. 30, after the hopes of exploiting the success had already faded, there came a German retort so full of menace that the public thereafter showed a strong distaste for premature celebrations. Yet if the battle in itself was a tragedy of error and missed opportunities, its eventual effect on the for-

for the Cambrai method, the initial impulse came from another source, where the lesson had been absorbed within three days.

On Aug. 3, 1917, an alternative proposal was drawn up at Tank Corps headquarters by the chief general staff officer, Col. Fuller. The preface to it contained this significant example of prevision: "... from a tank point of view the third battle of Ypres may be considered dead. To go on using tanks in the present condition will not only lead to good machines and better personnel being thrown away, but also to a loss of *morale* in the infantry and tank crews through constant failure. From an infantry point of view the third battle of Ypres may be considered comatose. It can only be continued at colossal loss and little gain. . . ."

Then came the alternative proposal, to restore British prestige, before the winter set in, by a tank blow against St. Quentin, as a strategical prelude to an advance towards Valenciennes the following spring. Discussion of this project brought out the objection that it required a combined British and French operation, which might lack the simplicity and smooth working essential to a novel method. Therefore, on Aug. 4, a second project was framed, for a great tank raid south of Cambrai. The word raid should be stressed, for, as originally conceived, the object was "to destroy the enemy's personnel and guns, to demoralize and disorganize him, and not to capture ground." As the preliminary notes stated, "the duration of the raid must be short—eight to 12 hours—so that little or no concentration of the enemy may be effected for counter-attacks."

Had this plan been followed there would have been no need to lament Nov. 30. For the raid a force of six tank battalions, supported by "one, or better two," divisions with extra artillery, was suggested, operating on an 8,000yd. front. The object, as proposed, was "to raid the re-entrant formed by the L'Escaut canal between Ribécourt-Crèvecœur-Banteux." The raiding force was to be divided into three groups, the main one to scour this canal-enclosed pocket, while the smaller groups formed offensive flanks on each side to protect the main operation.

The detailed project, from which the foregoing are extracts, was taken to Gen. Byng, commander of the 3rd Army, on Aug. 5. On Aug. 6 Byng went to G.H.Q., saw the commander-in-chief, and suggested an attack with tanks on Sept. 20. Sir Douglas Haig is understood to have been favourable to the idea, but counter-arguments, for concentrating every possible man in the Ypres area delayed its adoption. However, the continued lack of definite success at Ypres lent emphasis to an alternative, and on Sept. 7, as a result of a consultation at 3rd Army headquarters, a letter was addressed by Tanks Corps headquarters to G.H.Q. asking that the tanks might be withdrawn from the Ypres area, and suggesting two operations, one on the 1st Army front and one on the 3rd.

On Sept. 11 G.H.Q. approved the withdrawal of the bulk of the tanks and gave instructions to the Tank Corps to reconnoitre the Lens front (1st Army). After a report and project had been submitted to G.H.Q. the area was changed back to Cambrai, and on Oct. 25 the first general conference on the Cambrai operation was held. The date had been fixed for Nov. 20. Among the factors which induced the British command to approve the Cambrai scheme were the need of disarranging the enemy's plans of withdrawing troops from France to strengthen the Austro-German thrust against Italy, and the urgency of striking any such blow before the stream of German reinforcements released by the Russian revolution could swell to its full strength. Despite the heavy drain on British resources, caused by the Ypres offensive, these arguments prevailed.

**The Plan Adopted.**—The basis of the tactical plan was the use of a mass of tanks in a surprise onslaught, to replace the customary method of an intense preparatory bombardment by artillery. The historical interest of the Cambrai scheme centres around two points, the general plan and the tank plan.

The 3rd Army plan was (a) to break the German defensive system, the famous Hindenburg line, in the neck of land between the Canal de L'Escaut and the Canal du Nord; (b) to seize Cambrai, Bournon wood and the passages over the river Sensée; (c) to cut off the Germans in the area south of the Sensée and

tunes of the Allies was beneficent—it pointed the way to the victorious method of 1918.

**Origin of the Battle.**—The question of the origin of the Cambrai operations is of primary historical importance, both because of the outcome, and because of the method, of Nov. 20. The initial source is to be found in the third battle of Ypres, which opened on July 31, 1917, and died away three months later in the swamps of Passchendaele. The lesson of these operations was that the method of an overwhelming artillery bombardment stultified its own objects by rendering impassable the ground over which the advance was planned to follow. If the ultimate appreciation of this lesson by the High Command paved the way

west of the Canal du Nord; and (d) to exploit the success towards Valenciennes. The force allotted for this ambitious plan was the 3rd and 4th Army Corps, comprising six divisions and part of another, the Cavalry Corps of two divisions, 381 fighting tanks and approximately 1,000 guns. They were to be employed on a front extending from Gonnellieu to Havrincourt wood. The German defences opposing them consisted of the Hindenburg line system, and behind this the Hindenburg reserve line and the unfinished Beaufort-Masnières line. Thus of the original project there remained only the fundamental idea—the massed tank surprise, the tank method and the locality.

In the alterations to the original plan lay the germ of disaster. The raid had been transformed into a large-scale offensive, with far-reaching aims. Instead of scouring a pocket and withdrawing, an organized advance was to be made up a narrow lane bounded by two canals. As protection to a raid, these became a danger to such an attack, circumscribing the action of the tanks and preventing the formation of tank offensive flanks. Otherwise the ground was good, and ideally chosen indeed for the original purpose, being mostly rolling downland, excellent for tank movement. It was marked by two features, the Flesquières-Havrincourt ridge and Bourlon hill.

The fundamental weakness of the plan was not topographical, but the almost complete lack of reserves. To undertake such an important operation in such a condition was surely a violation of one of the cardinal axioms of war. There were local reserves, naturally, in most divisions, but there was no general reserve, unless the two cavalry divisions can be considered such—and, apart from their limited strength, the futility of so regarding them was amply shown in their fresh inability, in face of modern weapons, to influence the action.

The six divisions employed in the initial attack were all that the 3rd Army commander had at his disposal, for a plan that visualized a penetration beyond Cambrai towards Valenciennes. It is difficult to understand what was in mind as to the future, for without reserves complete success could only mean the creation of an excessively deep and narrow salient, requiring many divisions to hold it. It is true that the Guards and one or two other divisions could be made available, and were ultimately brought to the scene, but they were too far away for prompt intervention. The situation, indeed, had some reminder of Loos. The French also moved a special force forward in readiness to co-operate, but their aid was not called upon.

If the excuse be that the third battle of Ypres had drained the British of reserves, then it surely reflects on the choice of that swamp-like area and the failure to try earlier the method that at Cambrai unlocked the doors to decisive success. On the other hand, it may be urged that G.H.Q. put an initial time-limit of 48 hours on the operation. To this the reply is that if the lack of resources was appreciated, the objectives were excessively ambitious, and that the powerful raid originally proposed was far more in accordance with the principle of security than an offensive involving occupation of newly consolidated positions.

Turning now to the tank plan, the problems were to gain surprise, to cross the wide and deep obstacle of the Hindenburg line and to ensure co-operation between the infantry and tanks for their common security. Careful organization and the absence of a preliminary bombardment contributed to the accomplishment of the first object. The difficulty presented by the Hindenburg line was overcome by devising super-fascine, huge bundles of brush wood, which were carried on the nose of each tank and released on reaching the edge of the Hindenburg trenches; the tanks, working in sections of three, had thus the power to cross three successive obstacles. Thirdly, a strictly drill attack was worked out and practised, by which in each section an advanced guard tank moved about 100 yd. ahead of the two main body tanks, keeping down the enemy's fire and protecting the main body as they led the infantry forward. The infantry, moving in flexible file formations, followed immediately behind the main body tanks. While the tanks cleared a way for them through the deep belts of enemy wire and subdued the hostile machine-gun fire, the infantry acted as "moppers-up" to the tanks and were also

ready to protect them from the enemy's guns at close quarters. The one fault of the tank plan was that, against expert advice, the tanks attacked on the whole frontage instead of against selected tactical points, with the result that no tank reserve was kept for use in the later stages.

**The Battle.**—The preparations for the battle were made with great skill and secrecy, while to mislead the enemy as to the scale and frontage of the attack, gas and smoke attacks, dummy attacks with dummy tanks, raids and feints, were carried out on a wide front both north and south of the real sector of attack.

At 6.20 A.M. on Nov. 20 the tanks and infantry moved forward to the attack on roughly a six-mile front, achieving complete surprise and a demoralizing initial success at all points, save in the left centre in front of Flesquières. The cause of this one serious check appears to have been that the 51st Division here adopted formations of its own instead of conforming to those devised by the Tank Corps and adopted in all the other divisions. Whatever the reason, the result was that the infantry fell too far behind the tanks, lost the gaps in the wire and were stopped by machine-gun fire. This loss of touch lay also at the root of the losses which befell the tanks when they came over the ridge and under the close fire of several German batteries, for infantry accompanying them could have picked off the gunners.

But the effect of this battlefield incident has been unduly magnified. On the right the 12th, 20th and 6th Divisions secured their objectives rapidly, though the 12th had severe fighting at Lateau wood. The 20th Division passed through and captured Masnières and Marcoing, securing the passage of the canal at both and even the bridge intact at the latter. On the left the 51st and 62nd Divisions made a brilliant advance, advancing by night-fall as far as Anneux, over 2 m. in the rear of Flesquières. The Flesquières resistance was thus only an islet, cut off and overlapped by the waves which swept round its flanks and on to Marcoing, Anneux and even to the edge of Bourlon wood. A penetration of 5 m. had been made—the equivalent of months of heavy fighting and heavier losses on the Somme and at the third battle at Ypres. Decisive success was within the grasp of the British forces, the enemy's main defence systems had been overrun, only a half-finished line and the open country lay beyond. But the original divisions and the tank crews were exhausted, and apart from one squadron of the Canadian Fort Garry Horse the two cavalry divisions could contribute nothing toward fulfilling their rôle of exploitation.

On Nov. 21 local reserves made some further progress. The village of Flesquières fell at 8 A.M., and the 51st and 62nd Divisions pressed rapidly on, clearing the German salient formed by this resistance on the first day and carrying the tide of the British advance as far as Fontaine-Notre-Dame, 1½ m. beyond the high-water mark of Nov. 20. But on the right, little ground was gained—a relieving German division had arrived just in time to occupy the rear defence. The High Command's time-limit of 48 hours had expired, but owing to the menace of the uncaptured Bourlon hill, to the new British position, as well as to the hope of an enemy withdrawal and the desire to relieve the enemy pressure on Italy, the commander-in-chief decided to continue the offensive, placing a few fresh divisions at the disposal of the 3rd Army. But the Tank Corps, the essential cause of the early success, was tired out, men and machines—all had been staked on the first throw. The fresh attacks met with more failure than success against an enemy now braced to meet the danger.

**The German Counter-Attack.**—On Nov. 22 the Germans recaptured Fontaine-Notre-Dame; on the 23rd, the 40th Division with tanks captured the whole of Bourlon wood, but the attempts on Bourlon village and Fontaine-Notre-Dame failed. Bitter and fluctuating fighting followed; Bourlon and Fontaine-Notre Dame were won and lost again, and meanwhile there were signs of a strong German counter-thrust against the already over-strained attackers, most of whom had been kept in action unrelieved since Nov. 20. Unfortunately, moreover, warnings of the storm were received with scepticism in some of the higher commands. In the early morning of Nov. 30 the blow fell, the German army commander, von der Marwitz, making a convergent attack against

the northern and southern flanks of the salient which the British advance had created. In the north, round Bourlon wood, the attack was stopped after bitter fighting, but in the south, where the blow fell on the joint of the salient and also on the weakly held front to the south, it broke right through. This was a finely planned surprise assault, unheralded by any preliminary bombardment, and made more effective by the cloud of gas and smoke shells. Villers Guislain and Gonnelleu soon fell, and the thrust penetrated deeply behind the old British front line as far as Gouzeaucourt, overrunning gun positions and headquarters. Disaster was only averted by the superb counter-attack of the Guards Division, which recaptured Gouzeaucourt, and later, of the 2nd Tank Brigade, which brought out the value of this arm for defence.

Fresh attacks on Bourlon and Masnières failed, but further German progress was made towards Villers Plouich. The British position in the Masnières-Bourlon salient was thus rendered so precarious that on the night of Dec. 4-5 most of the salient was evacuated and the line drawn back roughly to the Flesquières ridge. Although the result left the British with a slight gain of ground on balance, and better still had a helpful influence on the Italian campaign, Cambrai would be remembered mainly as a tragedy of mistaken aims and lost opportunities, were it not for its revelation of a new key to victory, turned to effect in 1918.

**CAMBRIA**, the M. Lat. name for Wales. After the end of the western Roman empire the Cymric Celts held for a while both Wales and the land round the Solway (now Cumberland and adjacent regions), and the former came to be called Cambria, the latter Cumbria, though the two names were sometimes interchanged by early mediaeval writers.

**CAMBRIAN SYSTEM**, in geology, is the name applied to the oldest group of rocks in which fossils have been found in any abundance. Organic remains have, indeed, been discovered in still older beds, but they are rare and obscure. The name was originally proposed by Sedgwick and, as used by him, it included the Lower Silurian of Murchison, which is now commonly recognized as a separate system under the name Ordovician. Thus the Cambrian of the present day is the Lower Cambrian of Sedgwick. Other terms which have been used with approximately the same significance are Primordial Silurian and Taconic, the latter in America only. The original Taconic of Emmons has, however, proved to be a complex of various ages and the name has dropped out of use. Although the term Cambrian is now universally accepted, there are still differences of usage with regard to its precise limits. In England the Tremadoc beds, which in their fauna are intermediate between the Cambrian and the succeeding system, are usually included in the Cambrian; on the Continent the corresponding beds are placed in the Ordovician.

In general the Cambrian period was a quiet one. No violent crustal disturbances can be assigned to it and manifestations of volcanic activity are insignificant. Considerable changes of level are indicated by the nature of the sediments and by local discontinuities, but these changes were not accompanied by folding. Even the most considerable gaps in the succession are usually not marked by any definite unconformity and have often been overlooked till the examination of the included fossils showed that a part of the system was missing. In many areas, however, the beds have since undergone great earth-movements and the muds and sands of the period have been converted, as in Wales, into slates and quartzites. Where, as in Estonia, they have been little disturbed, they may remain nearly as soft as when laid down.

At one time it was imagined that the Cambrian faunas throughout the world were more uniform in character than those of later periods. It was even supposed that there was a similar uniformity in the nature of the deposits and, in particular, a conspicuous deficiency in limestone. Hence it was argued that during the Cambrian period the ocean waters were more evenly spread over the globe than they have been since, and that climatic differences were less marked. Such views, however, can no longer be held.

So great are the differences between the Cambrian faunas of western America and of northern Europe that the real difficulty is not to distinguish between them but to correlate them; and while limestone is absent from the Cambrian of Wales there are thousands of feet of limestone in the Cambrian of the Canadian Rockies.

**Life of the Period.**—Although the Cambrian fauna is the earliest of which we know more than traces, there is nothing primitive about it. It is very varied and includes many different classes of animals. The Protozoa are represented by radiolaria and sponges, the Coelentera by corals, by the earliest graptolites and even by casts of such delicate forms as medusae. The Echinodermata include crinoids, starfishes and cystideans. Annelids occur even in the oldest beds. Brachiopoda and Mollusca are locally numerous and various forms of Crustacea are found; but by far the most varied and abundant group is the Trilobita (*q.v.*), which includes a great variety of forms, ranging from the small and simple *Agnostus* to the large and many-segmented *Paradoxides*.

**Classification.**—Lithological divisions of a geological system have no more than a local value, and a grouping of the beds according to their fossil contents is much more widely applicable; but in the Cambrian there is nothing comparable, either in precision or in generality, with the graptolite zones of the Ordovician and Silurian or the ammonite zones of the Jurassic. It is true that many of the palaeontological zones established in Scandinavia can be recognized in Wales and even in Newfoundland, but in Western America and Eastern Asia the characteristic fossils of these zones are entirely absent. Even the broader palaeontological subdivisions of northern Europe cannot there be distinguished.

In Europe three divisions have long been recognized, each characterized by a special group of trilobites, after which it is named. These divisions are, in ascending order, the *Olenellus* series, the *Paradoxides* series, and the *Olenus* series. In this connection *Olenellus* and *Olenus* are used in a wide sense and must be understood to include allied forms. Neither *Olenellus* nor *Olenus* in the stricter sense ranges throughout the series named after it. The *Olenellus* group of trilobites seems to have been world-wide in its distribution, but through the greater part of America, Asia and Australia *Paradoxides* and *Olenus* and their allies are unknown, although the deposits of the period during which they lived are present. In America *Olenoides* series and *Dikelocephalus* series would be more appropriate terms; but it is not yet possible to establish any subdivision of the Cambrian system into series of universal applicability. We use such terms as Lower, Middle and Upper Cambrian: but it would be rash to assume, *e.g.*, that the Middle Cambrian of the Rockies corresponds in more than a general way with that of Wales or even of New Brunswick.

**Atlantic and Pacific Faunas.**—The Cambrian fauna of Wales is very like that of Scandinavia, many of the species being identical, and a similar fauna is also found in the extreme east of North America. But the Cambrian fossils of the north of Scotland are quite different and closely resemble those from the Appalachian region of Canada and the United States. There are, in fact, two distinct faunas which lived, no doubt, in separate seas. Between them lay a barrier of land which stretched from the Appalachian plateau across the Atlantic into Scotland.

In the Western Cordillera of Canada and the United States there is another abundant Cambrian fauna, very different from that of Wales but with a much closer affinity to that of the Appalachian area. A very similar fauna is found in China, and the Cambrian faunas of India and Australia are also closely related. It seems, therefore, that even in Cambrian times there was an Atlantic and a Pacific occupying part of their present sites and in some directions spreading far beyond.

It is not possible here to do more than indicate a few of the differences between the faunas of the two oceans. In the Atlantic fauna *Paradoxides*, *Olenus*, *Peltura*, *Parabolina*, *Leptoplastus* and several other allied genera play an important part; in the Pacific fauna they are unknown, though one or two species allied to *Olenus* have been found. The Pacific fauna includes a whole series of genera which are not found in the Atlantic area. There is a much greater variety of forms belonging to the same family

as *Olenellus* (the Mesonacidae); but perhaps the most striking feature is the number of large-tailed genera, such as *Asaphiscus* and *Ogygopsis*, which closely resemble the Asaphids characteristic of the European Ordovician. To a certain extent the place of *Paradoxides* is taken by *Olenoides* and its allies, the place of *Olenus* by *Dikelocephalus* and similar genera. The latter are not altogether absent from the Atlantic fauna but are much less numerous and varied.

The *Atlantic fauna* of the Cambrian period stretched from the mouth of the St. Lawrence on the west to the Lena on the east. The western limit is sharply defined, for while the Cambrian of eastern Newfoundland, New Brunswick, and eastern Massachusetts belongs to the Atlantic type, the corresponding beds of western Newfoundland and the Appalachian region are of Pacific type. Northwards the Atlantic fauna did not reach the Scottish Highlands, for there we find the fauna of the Appalachian sea. In eastern Europe, however, it extended into Vaigach island and farther east it stretched beyond the present continent of Asia to the New Siberian islands. Southwards it reached the Mediterranean region, for the Cambrian of the Spanish peninsula, Sardinia and the Dead sea belongs to this type.

The whole of the area included within these limits was not a single broad expanse of sea. The Cambrian fauna of Sardinia is very different from that of Scandinavia. Probably an incomplete land-barrier lay between, but the differences may be partly due to differences of temperature, depth or other conditions. In some cases an apparent difference between the faunas of two regions has been brought about by the absence in one of them of the deposits belonging to a part of the period.

On the western side of the present Pacific the *Pacific fauna* of the Cambrian period has been found in Manchuria, China, Indo-China, the central Himalayas, the Indus Salt range, Australia and Tasmania. On the eastern side it is found in the Western Cordillera of North America, in the Appalachian region and in the north of Scotland. Much of the interior of the United States was also covered by seas for some part of the period. The Appalachian Cambrian, for example, seems to have been laid down in a comparatively narrow gulf which north-eastward stretched as far as Scotland and south-westward entered the open ocean. The Cordilleran Cambrian is believed to have been deposited in a trough running along the line of the present Cordillera and separated from the ocean by a land-mass which occupied the site of the Cascade range. This trough is supposed to have been connected with an Arctic ocean in the north and an open Pacific towards the south. For the greater part of the period the Appalachian gulf and the Cordilleran trough were separated by land occupying most of the interior of Canada and the United States, but towards the close much of this area was covered by the sea. The Cambrian faunas of China, India and Australia, although all of Pacific type, show sufficient individuality to suggest that the seas in which they lived were not always in free communication.

**Europe.**—The principal Cambrian areas of Europe are in the north-west of Scotland, in Wales and the neighbouring counties of England, in Scandinavia, Estonia, Bohemia, the Spanish peninsula and Sardinia. Beds also occur in the Ardennes, Brittany, the Montagne Noire S. France, and in Germany and Poland.

It has already been remarked that the Cambrian of the north of Scotland belongs to the Pacific type. The rocks are chiefly sandstones and dolomitic limestones, the former predominating in the lower part of the series and the latter in the upper part. *Olenellus* occurs in the Fucoid beds, towards the middle of the series, but the Durness limestone, which forms the upper part, contains a very different fauna. Trilobites occur, but the most striking feature is the dominance of cephalopods and gasteropods, most of the species being unknown elsewhere in Britain but occurring in Canada. Comparison with that area suggests that the limestone belongs to the Upper Cambrian. Palaeontologically there is no trace of the Middle Cambrian, but as yet no break has been detected in the succession.

The accompanying table gives many of the more important local names of subdivisions used in various parts of northern Europe and shows their approximate correlation. It should be

remembered that the greater part of the "Passage Beds" of this table is placed by Continental geologists in the Ordovician. The *Dictyonema flabelliforme* zone, which in Wales occurs near the base of the Tremadoc, is usually taken as the line of demarcation.

|                           | Wales                            | Shropshire                              | Malvern                                  | Nuneaton            | South Scandinavia                      | Estonia         |

Note. The major gaps in the succession are indicated by the wavy lines.

In the strip of northern Europe which includes the areas mentioned in the table, the Cambrian attains its greatest thickness in Wales, where it has been estimated to exceed 12,000 feet. Upon the Welsh borders the thickness is much reduced, partly because there was less deposition throughout the period and partly because there is a considerable gap in the succession. Probably there was land here during the middle of the period and shallow water during the remainder. At Nuneaton, in Warwickshire, no break in deposition has been detected, but the total thickness is still much less than in Wales.

In Scandinavia the Alum shales, which are black shales with dark calcareous nodules and bands, are only some 400 ft. thick, but the succession is complete, except that there has been a certain amount of submarine erosion at the top of the shales. In Estonia, along the south shore of the Gulf of Finland, the total thickness of the Cambrian is not more than 100 ft., though borings at Reval and Leningrad show as much as 600 feet. But the small thickness here is certainly due in part to the total absence of the *Paradoxides* series and the imperfect development of the *Olenus* series. The Ungulite grit is placed in the latter, but *Olenus* and its congeners are absent. In spite of this great gap there is no unconformity, and the gap is indicated chiefly by the fact that the base of this grit contains fragments of the underlying beds.

In Bohemia the Cambrian consists of sandstones and conglomerates below, with a few obscure fossils, followed by greenish thick-bedded slates containing an abundant fauna. Trilobites predominate, and amongst them are species of *Paradoxides*. The *Olenellus* series may perhaps be represented by the unfossiliferous sandstones, but the *Olenus* series is absent, for the *Paradoxides* beds are followed immediately by the Ordovician. Even in the *Paradoxides* series most of the fossils are so distinct from those of Scandinavia as to suggest the possibility of an intervening land barrier. The occurrence of a Tremadoc fauna near Hof, Bavaria, points to an extension of the sea at the close of the period.

In southern Europe Cambrian beds are found in the Montagne Noire, the Spanish provinces of Leon, Asturias, Aragon and Seville, the Portuguese province of Alemtejo, and in Sardinia. In all these areas *Paradoxides* occurs, and the discovery of that genus near the Dead sea seems to indicate that in Middle Cambrian times a southern sea extended as far as Palestine. Neither *Olenellus* nor *Olenus* has been found, but in Portugal and Sardinia there is a lower fauna suggestive of the *Olenellus* series. The wide

distribution of *Archaeocyathus* limestones in southern Europe is noteworthy.

**Asia.**—Cambrian beds cover a wide area in Siberia and in Manchuria and northern China. They have also been found in Yunnan and Indo-China. In the central Himalayas there is an interesting development in Spiti, while south of the Himalayas a different type is found in the Salt range of the Indus. The occurrence of *Paradoxides* and other Cambrian fossils near the Dead sea, already referred to, suggests that the series of sandstones so widely spread in south-western Asia and northern Africa may include deposits of Cambrian age. So far as the fauna is concerned the Cambrian of the Dead sea and of Siberia belong to the Atlantic type, while in the remaining areas it is of Pacific type.

In Siberia the Cambrian covers a wide area extending from the Yenisei to the Lena. It has been found as far south as 56° N. Lat., and as far north as the New Siberian islands. In general the beds are nearly horizontal and consist of sandstones, shales and limestones. Much of it may certainly be referred to the *Paradoxides* series, though *Paradoxides* itself has not been recorded, but it is probable that the lower beds belong to the *Olenellus* series. In this lower division there is a considerable development of *Archaeocyathus* limestones containing *Dorypyge*.

In Manchuria and northern China, also, the Cambrian strata are in general horizontal, but along certain lines there has been very considerable disturbance, accompanied even by overthrusting. Two main divisions are recognized, the Man-t'o shale below and the Kiu-Lung group above. These are approximately the equivalents of the Lower Sinian and the Middle Sinian of Richtofen, who first described them. His Upper Sinian is Ordovician. The Man-t'o series has a thickness of 300–500ft., consisting chiefly of red shale with beds of sandstone and thin layers of limestone. Fossils are not abundant but Lower Cambrian and Middle Cambrian forms have been found. Amongst them is the trilobite *Redlichia*, a genus which has a wide distribution in Asia. It seems to belong to the same family as *Olenellus* although, unlike the other genera of that family, it has a distinct facial suture. It occurs chiefly in the Lower Cambrian but extends upwards into beds which are referred to the Middle Cambrian. The Kiu-Lung group, about 1,000ft. in thickness, consists of shales and limestones, the shales being green in colour. The fauna is very rich and includes a number of trilobite genera which have not yet been found elsewhere. There is, however, enough resemblance to the fauna of western North America to indicate that the lower part of the group belongs to the Middle Cambrian and the upper part to the Upper Cambrian.

In Yunnan and in the northern part of Indo-China the Cambrian beds are greatly disturbed but nevertheless have yielded an abundant fauna. In general it is very like that of northern China but includes one or two peculiar genera.

The Cambrian of Spiti consists of several thousand feet of slates and quartzites with thin bands of dolomite in the upper thousand feet. It is from this upper portion that fossils have been obtained. *Redlichia* has been found, and in the higher fossiliferous bands there are one or two forms which seem to be allied to *Olenus*, but no true *Olenus* has been discovered. The majority of the fossils seem to belong to the Middle Cambrian and have Pacific rather than Atlantic affinities.

The beds which are referred to the Cambrian in the Salt range consist chiefly of sandstone and shale with a very remarkable deposit of salt in the lower part of the series. Cambrian fossils occur in the *Neobolus* shales, which lie in the upper half of the series. Amongst them are *Redlichia* and other trilobites, brachiopods and mollusca.

**Australia and Tasmania.**—Cambrian beds occupy a wide area in Northern Territory, where they consist largely of limestones and attain a thickness of perhaps 7,000 feet. Thick sheets of basic lava below seem to belong to the period. In South Australia the system is found between Lake Eyre and Kangaroo island, and stretches across the Barrier range into New South Wales. In this southern area one of the most remarkable features is the presence of glacial deposits, fully 1,000ft. thick, towards the middle of the system. Higher up is a great development of *Archaeo-*

*cyathus* limestones. The fauna of the Australian Cambrian is distinctly Pacific in type, including *Redlichia* and large-tailed trilobites of Asaphid aspect. In Tasmania the Cambrian beds have yielded well-preserved casts of *Dikelocephalus*.

**North America.**—In the eastern part of Newfoundland, in New Brunswick and Cape Breton, and in the eastern part of Massachusetts the Cambrian is of Atlantic type. Even the individual zones which have been distinguished in Wales or Scandinavia may sometimes be recognized. On the whole recent researches tend rather to reduce than to increase the differences which have been observed. The *Protoleues* zone, for example, with its peculiar fauna, which was first recognized in New Brunswick, has since been discovered in Shropshire.

With the exception of these most eastern parts the American Cambrian is of Pacific type, the system attaining its greatest development in the Appalachian and Cordilleran troughs. The intervening space is largely concealed by later beds and where the Cambrian is exposed the Lower and Middle divisions are often, but not always, absent.

In the Appalachian trough the deposits are thickest and most continuous in the south. They become more sandy and pebbly towards the east, that is, towards the land-barrier which separated the trough from the Cambrian Atlantic. The Middle Cambrian is poorly represented in the north of the region and it seems that at that time the sea had retreated towards the south. But in Upper Cambrian times it spread northward again, and also overflowed the land-mass that separated it from the Cordilleran trough.

The Cordilleran trough contains perhaps the finest development of the system in the world, and certainly it has yielded the most abundant fauna. The beds are often very little disturbed or altered and consequently the fossils are remarkably well preserved. A whole series of genera have been described which are as yet unknown elsewhere. Mt. Stephen in the Canadian Rockies is perhaps the most famous of all the fossil localities, but very fine sections are also to be seen in California, Utah and Nevada. Towards the west the deposits become sandy, indicating the existence of a land-mass in that direction, which has been called Cascadia. It included the site of the present Cascade range.

The terminology of the North American Cambrian has varied greatly and it may be convenient to mention here the names that have been applied at different times to the major subdivisions. The Lower Cambrian has sometimes been called the Georgian, sometimes the Waucoban; the Middle Cambrian is often named the Acadian; the Upper Cambrian has been called the Potsdamian, the Saratogan or the Croixan. The name Ozarkian has been applied to the passage beds between the Cambrian and the Ordovician, but Ulrich, who first proposed the name, considers the Ozarkian to form a separate system, which has not been definitely identified outside America.

**South America.**—Cambrian beds have been found in Argentina and Bolivia, but are still very imperfectly known. It is, indeed, scarcely possible to say from the recorded fauna whether it is more closely allied to the Atlantic or to the Pacific type. The Argentine fossils suggest the Middle Cambrian, but the occurrence of *Peltura* in Bolivia points to the upper division of the system and to an Atlantic connection.

**BIBLIOGRAPHY.**—For the better-known areas no short list of original memoirs can be of any value. Perhaps the best summary of our knowledge of the Cambrian system throughout the world at the close of the 19th century is that by F. Frech in *Lethaea Geognostica*, Theil i., Band i. (Stuttgart, 1897). For later work the following references will be useful. Britain: *Handbook of the Geology of Great Britain*, ed. J. W. Evans (1928). Portugal: J. F. N. Delgado, *Faune cambrienne du Haut-Alemtejo*, Commun. Serv. Géol. du Portugal, vol. v. (1904). Siberia: Von Toll, *Mém. Acad. Imp. Sci. St. Pétersbourg*, ser. 8, vol. viii. no. 10 (1899), and *ibid.*, vol. ix. no. 1 (1899). China: Bailey Willis, C. D. Walcott, etc., *Research in China*, Carnegie Institution, vols. i. and ii. (1907), vol. iii. (1913). Yunnan and Indo-China: Various memoirs by J. Deprat and H. Mansuy, in *Mém. du Serv. géol. de l'Indochine*, vols. i., ii., iv., v. Spiti: H. H. Hayden, *Mem. Geol. Surv. by C. D. Walcott in the *Smithsonian Miscellaneous Collections* (vols. liii., lvii., lxiv., lxvii., lxxv.) (P. LA.)

**CAMBRIC.** A word derived from *Kameryk* or *Kamerijk*, the Flemish name of Cambrai, a town in the department of Nord, France, where the cloth of this name is said to have been first made. It was originally made of fine linen. There is a record of a privy purse expenditure in 1530 for cambric for Henry VIII.'s shirts. Cambric has been used for many years in the manufacture of handkerchiefs, collars, cuffs, and for fine underclothing; also for the best shrouds, and for fine baby linen.

The yarns for this cloth are of very fine quality, and the number of threads and picks often reaches and sometimes exceeds 120 per inch. Embroidery cambric is a fine linen used for embroidery. Batiste, said to be called after Baptiste, a linen-weaver of Cambrai, is a kind of cambric frequently dyed or printed. All these fabrics are largely copied in cheaper materials, mixtures of tow and cotton, and in many cases cotton alone, taking the place of the original flax line yarns.

**CAMBRIDGE, EARLS AND DUKES OF.** Under the Norman and early Plantagenet kings of England the earldom of Cambridge was united with that of Huntingdon, which was held among others by David I., king of Scotland, as the husband of earl Waltheof's daughter, Matilda. As a separate dignity the earldom dates from about 1340, when William V., count (afterwards duke) of Juliers, was created earl of Cambridge by King Edward III.; and in 1362 (the year after William's death) Edward created his own son, Edmund of Langley, earl of Cambridge, the title being afterwards merged in that of duke of York, which was bestowed upon Edmund in 1385. Edmund's elder son, Edward, earl of Rutland, who succeeded his father as duke of York and earl of Cambridge in 1402, appears to have resigned the latter dignity in or before 1414, as in this year his younger brother, Richard, was made earl of Cambridge. In the following year Richard was executed for plotting against King Henry V., and his title was forfeited, but it was restored to his son, Richard, who in 1415 became duke of York in succession to his uncle Edward. Subsidiary to the dukedom of York the title was held by Richard, and after his death in 1460 by his son Edward, afterwards King Edward IV., becoming extinct on the fall of the Yorkist dynasty.

In 1619 King James I., anxious to bestow an English title upon James Hamilton, 2nd marquess of Hamilton (d. 1625), created him earl of Cambridge, a title which came to his son and successor James, 3rd marquess and first duke of Hamilton (d. 1649). In 1651 when William, 2nd duke of Hamilton, died, his English title became extinct.

Again bestowed upon a member of the royal house, the title of earl of Cambridge was granted in 1659 by Charles II. to his brother Henry, duke of Gloucester, only to become extinct on Henry's death in the following year. In 1661 Charles, the infant son of James, duke of York, afterwards King James II., was designated as marquess and duke of Cambridge, but the child died before the necessary formalities were completed. However, two of James's sons, James (d. 1667) and Edgar (d. 1671), were actually created in succession dukes of Cambridge, but both died in childhood. After the passing of the Act of Settlement in 1701 it was proposed to grant an English title to George Augustus, electoral prince of Hanover, who, after his grandmother, the electress Sophia, and his father, the elector George Louis, was heir to the throne of England; and to give effect to this proposal George Augustus was created marquess and duke of Cambridge in Nov. 1706. The title lapsed when he became king of Great Britain and Ireland in 1727, but it was revived in 1801 in favour of Adolphus Frederick, the seventh son of George III. He and his son are dealt with below.

ADOLPHUS FREDERICK, duke of Cambridge (1774-1850), was born in London on Feb. 24, 1774. Having studied at the university of Göttingen, Adolphus Frederick served in the Hanoverian and British armies, and, in Nov. 1801, was created earl of Tipperary and duke of Cambridge, becoming a member of the privy council in the following year. The duke is chiefly known for his connection with Hanover. In 1815, on the conclusion of the war, the electorate of Hanover was raised to the rank of a kingdom, and

in the following year the duke was appointed viceroy. He held this position until the separation of Great Britain and Hanover in 1837. He died in London on July 8, 1850. In 1818 he married Augusta (1797-1889), daughter of Frederick, landgrave of Hesse-Cassel. He left three children: his successor, George; Augusta Caroline (b. 1822), who married Frederick William, grand duke of Mecklenburg-Strelitz; and Mary Adelaide (1833-1897), who married Francis, duke of Teck.

GEORGE WILLIAM FREDERICK CHARLES, duke of Cambridge (1819-1904), was born at Hanover on March 26, 1819. He was thus about two months older than his cousin, Queen Victoria, and was for that period in the line of succession to the British throne. In Nov. 1837, after he had served for a short time in the Hanoverian army, he became a colonel in the British army and was attached to the staff at Gibraltar from Oct. 1838 to April 1839. After serving in Ireland with the 12th Royal Lancers he was appointed in April 1842 colonel of the 17th Light Dragoons (now Lancers). From 1843 to 1845 he was colonel on the staff in the Ionian islands, and was then promoted major-general. In Oct. 1846 he took command of the Limerick district, and shortly afterwards of the Dublin district. In 1850 his father died and he succeeded to the dukedom. Being appointed inspector of cavalry in 1852, he held that post until 1854, when, upon the outbreak of the Crimean War, he was placed in command of the 1st division (Guards and Highland brigades) of the British army in the East. In June of the same year he was promoted lieutenant-general. He was present at the battles of the Alma, Balaklava, and Inkerman, and at the siege of Sevastopol. On July 15, 1856, he was appointed general commanding-in-chief, on Nov. 9, 1862, field-marshal, and by letters patent, 1887, commander-in-chief. The long period during which he held the command of the army was marked by many changes. The Crimean War led to a regrouping of the departments, which, with the whole personnel of the army, were brought under the authority of the secretary of state for war. But only in 1870, after the successes of Prussia had created a profound impression, were drastic changes introduced by Cardwell into the entire fabric of the army. The objects of the reformers of 1870 were undoubtedly wise; but some of the methods adopted were strongly resented by the duke of Cambridge, whose views were shared by the majority of officers. Further changes were inaugurated in 1880, and again the duke found much to criticize. His opinions stand recorded in the voluminous evidence taken by the numerous bodies appointed to inquire into the condition of the army. They show a sound military judgment, and, as against innovations as such, a strong attachment to the old regimental system. That this judgment and this attachment were not so rigid as was generally supposed is proved by his published correspondence. The duke invariably accepted and loyally endeavoured to carry out the measures on which the Government decided.

Throughout his long term of office the duke of Cambridge evinced a warm interest in the welfare of the soldier, and great experience combined with a retentive memory made him a master of detail work. Belonging to the older generation of soldiers, he could not easily adapt himself to the new conditions; and in dispensing patronage he was somewhat distrustful of originality, while his position as a member of the royal family tended to narrow his scope for selection. He was thus inclined to be influenced by considerations of pure seniority, and to underrate the claims of special ability. He resigned the commandership-in-chief on Nov. 1, 1895, and was succeeded by Lord Wolseley, the duties of the office being considerably modified. He was at the same time gazetted honorary colonel-in-chief to the forces. He was made ranger of Hyde park and St. James's park in 1852, and of Richmond park in 1857; governor of the Royal military academy in 1862, and its president in 1870, and personal aide-de-camp to Queen Victoria in 1882. He died on March 17, 1904, at Gloucester house, London. The chief honours conferred upon him were: G.C.H., 1825; K.G., 1835; G.C.M.G., 1845; G.C.B., 1855; K.P., 1861; K.T., 1881. From 1854 he was president of Christ's hospital. The duke of Cambridge was married to Louisa Fairbrother, who took the name of FitzGeorge. She died in 1890.

See Rev. E. Sheppard, *George, Duke of Cambridge; a Memoir of his Private Life* (1906); and Willoughby Verner, *Military Life of the Duke of Cambridge* (1905). For the negotiations attending his resignation see J. A. Spender, *Life of Sir Henry Campbell-Bannerman* (1923), vol. i. ch. ix. pp. 148-154.

**CAMBRIDGE, ADOLPHUS CHARLES, MARQUESS OF** (1868-1927), elder brother of Queen Mary, was born at Kensington Palace, London, on Aug. 13, 1868, the son of the Duke of Teck and his wife Princess Mary of Cambridge, and died on Oct. 24, 1927. He was educated at Wellington college, and entered the 17th Lancers at the age of 19, being transferred in 1910 to the 1st Life Guards, of which he became lieutenant-colonel. The public service of the marquess of Cambridge was varied and strenuous. He served in the South African War, was military attaché in Vienna (1904-09), and during the World War temporary assistant military secretary at the War Office and then military secretary to the Commander-in-chief in France. He had succeeded in 1900 to his father's title as duke of Teck, but in 1917 German titles in the British royal family were abandoned, and the duke was created marquess of Cambridge. He married, in 1894, Lady Margaret Grosvenor, daughter of the 1st duke of Westminster. He was succeeded in the marquessate by his elder son George Francis (born on Oct. 11, 1895).

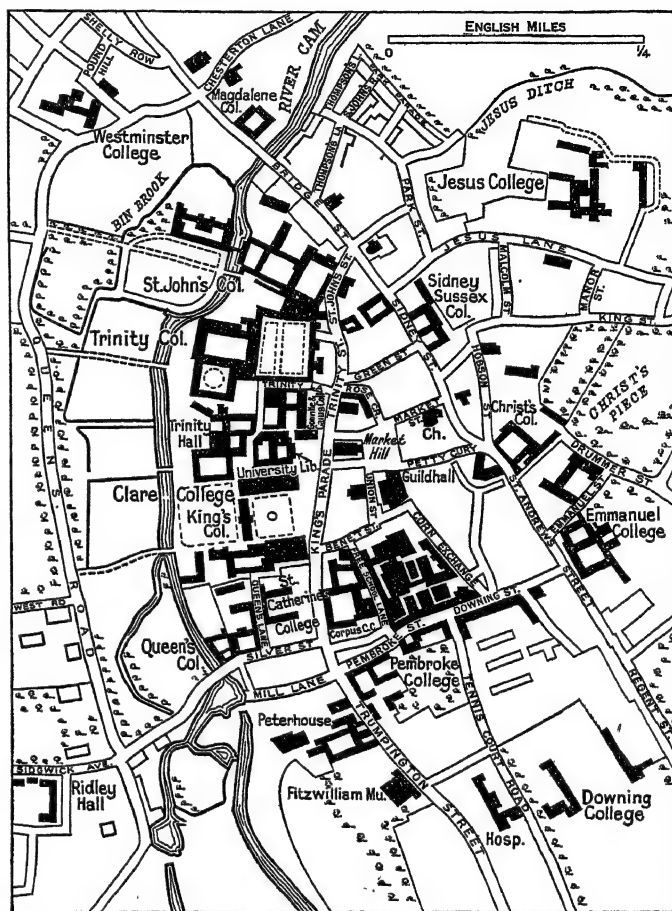

**CAMBRIDGE, RICHARD OWEN** (1717-1802), English poet, was born in London on Feb. 14, 1717, and died at Twickenham on Sept. 17, 1802. He was educated at Eton and at St. John's college, Oxford, and went into residence at Lincoln's Inn in 1737. Four years later he married, and went to live at his country seat of Whitminster, Gloucestershire. In 1751 he removed to Twickenham, where he enjoyed the society of many notable persons. Horace Walpole in his letters makes many jesting allusions to Cambridge in the character of news-monger. His chief work is the *Scribleriad* (1751), a mock epic poem, the hero of which is the Martinus Scriblerus of Pope, Arbuthnot and Swift.

*The Works of Richard Owen Cambridge, Esq., including several Pieces never before published, with an Account of his Life and Character by his Son, George Owen Cambridge* (1803), includes, besides the *Scribleriad*, some narrative and satirical poems, and about 20 papers originally published in Edward Moore's paper called *The World*. His poems are included in A. Chalmers's *English Poets* (1816).

**CAMBRIDGE**, a municipal and parliamentary borough, the seat of a university, and the county town of Cambridgeshire, England, 56 m. N. by E. of London by the L.N.E.R. and served also by the L.M.S.R. Area 5,457 acres. Pop. (1931) 66,803. It lies at the southern border of the Fen country, at an elevation of only 30 to 50 ft. above sea-level. The greater part of the town is situated on the right bank of the Cam, a tributary of the Ouse, but suburbs extend across the river. To the south and west the slight hills bordering the fenland rise gently. The borough returns one member to parliament.

Cambridge owed its growth to its command of a ford over the River Cam on a natural line of communication between the east and the midlands of England, flanked on the one hand by the deep forests which covered the uplands, on the other by the unreclaimed fens. The importance of this highway may be judged from the number of early earthworks, including Castle Hill at the north side of the present town. Roman remains discovered in the same locality give evidence of the existence of a small town or village at the junction of roads; the name of *Camboritum* is usually attached to it, but without certainty. The modern name of Cambridge has usually been derived from a corruption of the original name Grantebrycge or Grantabridge (Skeat); but it has been suggested that the name Cantebrig was very early given to that quarter of the town near the Cante brig. Cambridge castle was built in this quarter, close to the bridge, by the Conqueror, as a base of operations against Hereward the Wake and the insurgents of the fenland, and the name spread to the whole town, the similarity between the names Grantebrig and Cantebrig playing some part in this extension (see A. Gray, *The Dual Origin of the Town of Cambridge*, p. 31). Granta is the earlier and still an alternative name of the river Cam, this more common form having been adopted in sympathy with the modern name of the town. Cambridge had a further importance from its position at

the head of river navigation, and a charter of Henry I., in which the town is already referred to as a borough, grants it exclusive rights as a river-port, and regulates traffic and tolls. The wharves lay principally along that part of the river where are now the celebrated "backs" of some of the colleges. The great Sturbridge or Stourbridge fair at Barnwell, formerly one of the most important in England, is a further illustration of the ancient

PLAN OF CAMBRIDGE SHOWING THE SITUATION OF THE PRINCIPAL COLLEGES. SEE CAMBRIDGE UNIVERSITY

commercial importance of Cambridge; the oldest known charter concerning it dates from the opening of the 13th century, though its initiation may perhaps be placed a century before. From the 14th century onward materials were taken from the castle by the builders of colleges while the gatehouse, the last surviving portion, was removed in 1842. See CAMBRIDGE UNIVERSITY below.

**CAMBRIDGE**, a town on the "eastern shore" of Maryland, U.S.A., on the broad estuary of the Choptank river, near Chesapeake bay; a port of entry and the county seat of Dorchester county. It is served by the Pennsylvania railroad and by steamers. The population in 1920 was 7,467 and it was 8,544 in 1930. It is the business centre of a prosperous farming region; a shipping point for fish, oysters and oyster-shells, and agricultural products; and has a large oyster packing industry, vegetable canneries, and other factories. The commerce of its harbour (navigable through the year) amounted in 1925 to 67,090 tons, valued at \$4,999,344. Cambridge was founded in 1684, and was chartered as a town in 1900.

**CAMBRIDGE**, a city of Massachusetts, U.S.A., on the Charles river, opposite Boston; the county seat of Middlesex county. It is served by the Boston and Maine railroad and the local transportation system of the Boston metropolitan area, and for freight by the Boston and Maine, the Boston and Albany and a belt line which connects with the New York, New Haven and Hartford. The area of the city is 6.25 sq. miles. The population

in 1920 was 109,694, of whom 32,104 were foreign-born white and 5,334 were negroes; and was 113,643 in 1930.

Old Cambridge, centring at Harvard square, has been to Americans a symbol of culture ever since the founding of Harvard college (*q.v.*) in 1636. Adjoining it has developed in the 20th century a commercial and industrial centre which now ranks third among the manufacturing cities of the State. The first printing-press in America was set up here in 1639, and a publishing business flourished through the 17th century. As long ago as 1850 there were glassware factories employing 500 persons. In the early '70s was begun the reclamation of two square miles of tide-covered marshlands for a manufacturing district. Rapid expansion, however, began in 1912, when the opening of the underground railway brought the business section of Boston within three minutes of Cambridge, and it was further stimulated by the war-time boom and by the development of motor-trucking, which gave direct access (without encountering the heaviest traffic congestion of Boston) to all the steamship piers, to the freight-yards of all the railroads entering Boston and to the suburban district of the metropolitan area. In 1927 there were 355 manufacturing establishments, and their output for the year was valued at \$176,000,000. The leading industries are printing and publishing and the manufacture of soap, candy, bakery products, electrical machinery and apparatus, foundry and machine-shop products and rubber goods. Most of the large New England industries are represented to some extent. The manufacturing as a whole is clean and unobjectionable in character. Slaughtering and meat-packing, formerly the principal industries, have almost disappeared with the rise of the packing centres of the middle west. The industrial growth has been advantageous as an offset to the large proportion of tax-exempt holdings in the city, while encroachment of manufacturing on the historic residential and educational sections has been obviated by zoning regulations. A city-planning board was created by ordinance in 1913. Modern transportation facilities have made Cambridge also an important distributing centre. Many national producers have established here their Boston headquarters; several Boston department stores have erected warehouses; and the Boston and Maine railroad in 1927 moved its general offices to Cambridge. The assessed valuation of property in 1927 was \$173,602,700, about \$1,400 per capita.

In addition to Harvard university (*q.v.*) the older educational institutions include Radcliffe college for women (1879), affiliated with Harvard; the Episcopal theological school (1867); and the New-Church (Church of the New Jerusalem) theological school (1866). Andover theological seminary (Congregational) moved to Cambridge in 1908, after a notable century in Andover. In 1915 the Massachusetts Institute of Technology (*q.v.*) moved from the site it had occupied in Boston for 50 years to a tract of 80 ac. on the Cambridge side of the Charles river basin.

The shaded irregular streets around Harvard square are full of historic and literary associations. The site of Cambridge was selected by Governor Winthrop and others in 1630 for the capital of the Massachusetts Bay Colony, but Boston's position was seen to have the advantage both for commerce and for defence. The town records (published) are continuous since 1632. The settlement was at first called New Towne, but in 1638, after the founding of Harvard, was named after the English university town. General Synods of the New England churches met here in 1637 and 1647 to settle disputed points of doctrine and from here in 1636 Thomas Hooker's congregation left for Connecticut. Here camped the first American army at the outbreak of the Revolution, and from it went the detachment which entrenched on Bunker Hill. Under an elm which stood until 1923 Washington (according to tradition) took command of the Continental army on July 3, 1775. The convention which framed the Constitution of Massachusetts met here in 1779-80. In Apthorp House (1760) Gen. Burgoyne and his officers were lodged as prisoners of war in 1777. Vassall or Craigie House (1759) was occupied by Washington in 1775-76, and later was the home of Edward Everett, Joseph E. Worcester, Jared Sparks and (1837-82) Henry Wadsworth Longfellow. In "Elmwood" (1767) James Russell Lowell was born and lived all his life; and there are many associations with Oliver Wendell

Holmes, Louis Agassiz, Charles Eliot Norton, John Fiske, Amy Lowell and many other men and women of note in the literary and scientific history of America.

The original town of Cambridge was very large. From it Newton was set off in 1691; Lexington in 1713; Brighton in 1837; and Arlington in 1846. The city was chartered in 1846. In 1850 the population was 15,215; in 1870, 39,634; in 1900, 91,886.

See Lucius R. Paige, *History of Cambridge, Massachusetts, 1630-1877* (Boston, 1877); T. W. Higginson, *Old Cambridge* (1899); *Historic Guide to Cambridge* (Cambridge, 1907); and Arthur Gilman (ed.), *The Cambridge of Eighteen Hundred and Ninety-Six* (Cambridge, 1907).

**CAMBRIDGE**, a city of eastern Ohio, U.S.A., on a hill 800 ft. above sea-level; the county seat of Guernsey county. It is on Federal highways 21, 23 and 40, and is served by the Baltimore and Ohio and the Pennsylvania railways. The population in 1920 was 13,104, (92.9% native white) and was 16,129 in 1930 by Federal census. Coal, oil, natural gas, clay and iron are found in the vicinity, and the city has important manufactures of iron, steel, tin, glass and pottery. The output of its factories in 1925 was valued at \$9,243,898. The first settlers here came from the Isle of Guernsey in 1798. A town was laid out in 1806 and the city was chartered in 1893.

**CAMBRIDGE PLATONISTS**, a school of philosophico-religious thinkers which flourished mainly at Cambridge University in the second half of the 17th century. The founder was Benjamin Whichcote and the chief members were Ralph Cudworth, Richard Cumberland, Joseph Glanvill, Henry More and John Norris (*see* separate articles). Other less important members were Nathanael Culverwel (d. 1651), Theophilus Gale (1628-1678), John Pordage (1607-1681), George Rust (d. 1670), John Smith (1618-1652) and John Worthington (1618-1671). They represented liberal thought at the time and were generally known as Latitudinarians. Their views were due to a reaction against three main tendencies in contemporary English thought: the sacerdotalism of Laud and his followers, the obscurantist sectaries and, most important of all, the doctrines of Hobbes. They consist chiefly of a reconciliation between reason and religion, resulting in a generally tolerant spirit. They tend always to mysticism and the contemplation of things transcendental. In spite of inaccuracy and the lack of critical capacity in dealing with their authorities both ancient and modern, the Cambridge Platonists exercised a valuable influence on English theology and thought in general. Their chief contributions to thought were Cudworth's theory of the "plastic nature" of God, More's elaborate mysticism, Norris's appreciation of Malebranche, Glanvill's conception of scepticism as an aid to Faith, and, in a less degree, the harmony of Faith and Reason elaborated by Culverwel. The one doctrine on which they all combined to lay especial emphasis was the absolute existence of right and wrong quite apart from the theory of divine authority. Their chief authorities were Plato and the Neo-platonists (between whom they made no adequate distinction), and among modern philosophers, Descartes, Malebranche and Boehme. From these sources they attempted to evolve a philosophy of religion, which would not only refute the views of Hobbes, but would also free theology finally from the errors of scholasticism, without plunging it in the newer dangers of unfettered rationalism (*see* ETHICS, HISTORY OF).

**CAMBRIDGESHIRE**, an eastern county of England, bounded north by Lincolnshire, east by Norfolk and Suffolk, south by Essex and Hertfordshire, and west by Bedfordshire, Huntingdonshire and Northamptonshire. The greater part of the county falls within the district of the Fens, and is flat, lying only a few feet above sea-level, and intersected with innumerable drainage channels. The physical characteristics of this district, and the history of its reclamation are more fully treated under the heading FENS. Except in the south of the county the scenery is very monotonous and open: such isolated elevations as the Gog Magog Hills, south-east of Cambridge, and the hillock on which

the city of Ely stands, are very conspicuous. The principal rivers are the Ouse and its tributaries in the south and centre, and the Nene in the north: they flow for the most part in artificial channels, of which those for the Ouse, two great parallel cuts between Earith and Denver Sluice, in Norfolk, are called the Bedford Rivers. The old channel of the Ouse, from Ely to Denver (below which are tidal waters), is followed chiefly by the Cam or Granta, the Lark, which with its feeder, the Kennett, forms part of the boundary of the county with Suffolk, and the Little Ouse, forming part of the boundary with Norfolk.

In the south and south-east the chalk gives a continuous belt of dry uplands, clothed with scattered groves of beech. North of this, but best developed in the south-west, is a clay and greensand area; the rest of the county is alluvial Fenland. The general strike of the rocks is along a south-west and north-east line, and the dip is south-easterly. The oldest rock is the jurassic Oxford Clay, forming an irregular strip of rising ground west of Cambridge, reaching from Croxton by Conington and Fenny Drayton to Willingham and Rampton. Eastward and northward it forms the floor of the Fen country, and at Thorney and Whittlesea rises in "islands" through the level fen alluvium. The Coralline Oolite, with the Elsworth or St. Ives rock at the base, occurs as a small patch, covered by Greensand, at Upware. Elsewhere its place is taken by the Ampthill Clay passage beds between the Oxford and Kimmeridge Clays. The latter clay lies in a narrow strip by Papworth St. Agnes, Oakington and Cottenham; a large irregular outcrop surrounds Haddenham and Ely. Above the Kimmeridge Clay comes the Lower Greensand, sandy for the greater part, but here and there hardened into "Carstone" which has been used as an inferior building-stone. This formation extends from the border by Gamlingay, Cuxton and Cottenham, and appears again in outliers at Upware, Ely and Haddenham. The Gault forms a strip of flat ground, 4 to 6 m. wide, and 200 ft. thick in the south-west, running roughly parallel with the course of the river Cam, from Guilden Morden through Cambridge to Soham. At the bottom of the chalk is the Chalk Marl, 10 to 20 ft. thick, with a nodule-bearing layer at its base, known as the Cambridge Greensand. This bed has been largely worked for the nodules and for cement; it contains many fossils derived from the Gault below. Several outliers of Chalk Marl lie upon the Gault west of the Cam. Much glacial boulder clay covers all the higher ground of the county. Near Ely there is a remarkable mass of chalk, evidently transported by ice, resting on and surrounded by boulder clay. Plateau gravel caps some of the chalk hills, and old river gravels occur at lower levels with the bones of mammoth, rhinoceros and other extinct mammals. The low-lying Fen beds are marly silt with abundant peat beds and buried forests; at the bottom is a gravel layer of marine origin. *See FENS.*

**Early Settlement.**—Neolithic types of flint implements are very common in parts of the county, implying a prolonged period of occupation in the areas bordering on the fens, around Mildenhall (part of the East Anglian heathlands) and along the river Cam south-westwards. "Beakers," a type of pottery introduced from the continent after 2000 B.C., occur in the Anglian river valleys and on the edge of the fens. Throughout the bronze age, settlement seems to have been mainly concentrated in the strip east of the Cam from Royston north-eastwards to Soham, including the chalk escarpment. Hoards of the late bronze age come mainly from the borders of the fens and from the Cam valley; several have been found in the fens; inland waterways were evidently important. There is also evidence that raw material (copper and tin) was brought to the region from the south-west along the Icknield Way. The forested valleys in the chalk of the south-east had been penetrated to some extent. Invaders reached the region during the early iron age, in the La Tène and possibly in the preceding Hallstatt period. Penetration took place by the Wash and also from the south, and the La Tène culture profoundly influenced provincial Roman craftsmanship. Population was densest in the fertile valley of the Cam; the southern fens and the forests west of Cambridge were very barren. Several hill-forts were occupied in the south of the county and the present sites of villages and towns in many cases seem already to have been fixed. The

coming of the Romans established the pre-eminence of Cambridge, a nucleus of trackways, the crossing-place of the Cam nearest the upper limit of the tidal influence. A remarkable feature of the Romano-British period is the widespread occurrence of finds in what had been marshland as well as on the fen islands. That a good deal of drainage was done is probable (the Car Dyke between Cam and Great Ouse is of Roman construction), and the forested claylands were also penetrated. Southern Cambridgeshire lay athwart the main Roman road to the north (Ermine Street) whence Ake-man street branched north-eastwards, west of the Cam, to Cambridge and Norfolk.

The earliest English settlements were made in the 5th century. The Anglo-Saxon conquest was followed by a period of contraction but by the time of the Domesday Survey, the range of settlement was in its essentials that of modern times. The districts corresponding to the counties of Huntingdonshire and Cambridgeshire were distinguished as the lands of the North Gyrwas and the South Gyrwas respectively. At this period the fen-district stretched southward as far as Cambridge, and the essential unity which it preserved is illustrated later by its inclusion under one sheriff, chosen in successive years from Cambridgeshire proper, the Isle of Ely and Huntingdonshire. After the treaty of Wedmore, the district became part of the Danelaw. On the expulsion of the Danes by Edward in the 10th century it was included in East Anglia, but in the 11th century was again overrun by the Danes, who burnt Cambridge. The Saxon Chronicle records the shire's valiant resistance to the invaders in 1010, when the rest of East Anglia had taken ignominious flight. The shire-system of East Anglia was not definitely settled before the Conquest, but during the Danish occupation of the 9th century the district possessed a certain military and political organization round Cambridge, its chief town, whence probably originated the constitution and demarcation of the shire. At the time of Domesday (1086) the county was divided as now, except that the Isle of Ely, which then formed two hundreds having their meeting-place at Witchford, is now divided into the four hundreds of Ely, Wisbech, North Witchford and South Witchford, while Cambridge formed a hundred by itself. Cambridgeshire was formerly included in the diocese of Lincoln, until, on the erection of Ely to a bishop's see in 1109, almost the whole county was placed in that diocese. The Isle of Ely formerly constituted an independent franchise but its privileges were abridged in the reign of Henry VIII., though the bishop still retains certain exceptional rights.

From the time of Hereward the Isle of Ely was intimately concerned with the great political struggles of the country. It was defended against Stephen by Bishop Nigellus of Ely, who fortified Ely and Aldreth, and the latter in 1144 was held for the empress Maud by Geoffrey de Mandeville. The Isle of Ely was seized by the followers of Simon de Montfort in 1266, but in 1267 was taken by Prince Edward. The county showed much sympathy with the Reformation. In the civil war of the 17th century Cambridgeshire was one of the associated counties in which the king had no party, but the university helped him with plate and money.

The county is rich architecturally. Norman buildings include Sturbridge chapel, near Cambridge, and the parish church of Thorney, a portion of the church of an abbey founded or re-founded by Ethelwold, bishop of Winchester, as a Benedictine monastery in 972. The lepers' hospital to which Sturbridge chapel belonged was granted a fair by King John which is still held in September. The magnificent cathedral of Ely (*q.v.*) and the rich college buildings and chapels of Cambridge (*q.v.*) are outstanding treasures. At Swaffham Prior there are remains of two churches in one churchyard, the tower of one being good Transitional Norman, of the other mainly Perpendicular. Among many Early English examples the church of Cherry Hinton near Cambridge may be mentioned. The churches of Trumpington and Bottisham are fine specimens of the Decorated style. As Perpendicular examples the tower and spire of St. Mary's, Whittlesey, and the rich wooden roof of Outwell church, may be selected. Monastic remains are scanty. Excluding the town of Cambridge there are no domestic buildings of special note with the exception of Sawston Hall (1557-1584) in the south.

**Agriculture.**—The Domesday Survey mentions over ninety mills and numerous valuable fisheries, especially eel fisheries. The county had a flourishing wool industry in the 14th century, and became noted for its worsted cloths. The Black Death of 1349 and the Wars of the Roses brought severe depression, and in 1439 several Cambridgeshire towns obtained a remission of taxation on the plea of poverty. In the 16th century barley for malt was grown in large quantities in the south, and the manufacture of willow baskets was carried on in the fen districts. Saffron was extensively cultivated in the 18th century, and paper was manufactured near Sturbridge. Sturbridge fair was at this period reckoned the largest in Europe, the chief articles of merchandise being wool, hops and leather; and the Newmarket races and horse-trade were already famous. Large waste areas were brought under cultivation in the 17th century through the drainage of the fen district, completed about 1652 under Cornelius Vermuyden, a Dutchman. The coprolite industry was very profitable for a short period from 1850 to 1880, and its decline was accompanied by a general industrial and agricultural depression.

Cambridgeshire is one of the principal grain-producing counties in England. Cereal growth is favoured by the flat fertile lands, and by the dry climate. About 85% of the total area is under cultivation, and an unusually small proportion is under permanent pasture. Wheat is the chief grain crop, but large quantities of barley and oats are also grown. Potatoes occupy a large and increasing area in the Isle of Ely, and sugar-beet is increasingly grown. Dairy-farming is especially practised in the south-west, where the district of the Cam valley has long been known as the Dairies; and much butter and cheese are sent to the London markets. Sheep are pastured extensively on the higher ground. Fruit-growing and market-gardening are important in many parts. There is no large manufacturing industry common to the county in general.

**Communications.**—The principal railway serving the county is the L.N.E., which has numerous branch lines centring chiefly upon Cambridge, Ely and March. Communications are also maintained by the L.M.S.R. and by the M. and G.N.Jt.R. The artificial waterways provide the county with an extensive system of inland navigation.

**Population and Administration.**—The area of the administrative county, excluding that of the Isle of Ely is 315,168 acres. Pop. (1931) 140,004. The ancient county includes the two administrative counties. The liberty of the Isle of Ely was formerly of the independent nature of a county palatine, but ceased to be so under acts of 1836 and 1837. Its area is 238,073 acres. Pop. 77,705. Cambridgeshire contains seventeen hundreds. The municipal boroughs are Cambridge, the county town (pop. 66,803) and Wisbech (12,005) in the Isle of Ely. The urban districts are: Chatteris (5,153), Ely (8,382), March (11,276) and Whittlesey (8,299), all in the Isle of Ely. The town of Newmarket, which, although wholly within the administrative county of West Suffolk, is mainly in the ancient county of Cambridgeshire, is famous for its race meetings. The county is in the south-eastern circuit and assizes are held at Cambridge. Each administrative county has a court of quarter sessions. There are 168 entire civil parishes in the two administrative counties. Cambridgeshire is almost wholly in the diocese of Ely and the archdeaconries of Ely and Sudbury, but small portions are within the dioceses of St. Albans and Norwich. There are 194 ecclesiastical parishes or districts wholly or in part within the county. The university of Cambridge returns two members. The administrative county, exclusive of the parliamentary borough of Cambridge returns one member to the House of Commons.

See C. C. Babington, *Ancient Cambridgeshire* (1883); R. Bowes, *Catalogue of Books printed at or relating to Cambridge* (Cambridge, 1891 et seq.); E. Conybeare, *History of Cambridgeshire* (London, 1897); also Cyril Fox, *The Archaeology of the Cambridge Region* (1923).

**CAMBRIDGE UNIVERSITY.** (See also UNIVERSITIES.) Schools of some sort certainly existed in Cambridge in the twelfth century, but we cannot speak of anything approaching a university in the technical sense, a *studium generale*, until the thirteenth. The reputation of Cambridge teaching was good

enough to attract a number of Oxford students in 1209, when the lectures at their own university were suspended, and from this date Cambridge flourished. It had a chancellor, recognised by king and pope as early as 1226, and, before the end of the century, had a constitution modelled on that of Oxford and Paris. "Nations" appear in 1261, there were two proctors or "rectors," and the usual four faculties. The supreme authority lay in the "full" congregation of regents and non-regents; in 1401 the chancellor was dispensed from seeking confirmation from the bishop of Ely, and in 1432 he was made entirely independent of him. Throughout the middle ages, the town was kept, as far as possible, rigorously subject to the university. In 1318, a bull founding the university was obtained from Pope John XXII., although this meant nothing more than a formal recognition of its existence by Rome. Compared with Oxford, its history was insignificant until the fifteenth century, when it became the home of orthodoxy, the other having been left, by Wyclif's career, under a cloud of suspicion of heresy. By the fifteenth century, too, the Mendicant Orders had made Cambridge an important centre of their educational work in the east of England.

**Colleges and Their Foundations.**—Slowly the need for colleges and hostels became apparent. There were many of the latter, but the former, better endowed and equipped, have lasted and grown. The first college to be founded—after an abortive attempt at St. John's Hospital—was Peterhouse, 1284, on the model of Merton college, Oxford. University Hall, 1326, became Clare Hall in 1336; Pembroke was founded in 1347; Gonville Hall in 1349 (enlarged in 1558 into Gonville and Caius college); Trinity Hall, 1350; Corpus Christi, 1352; King's, 1441; Queens', originally St. Bernard's, 1446, re-founded in 1475; St. Catharine's, 1475; Jesus, 1497; Christ's, 1505 (absorbing God's House which had been founded in 1441); St. John's, 1511; Magdalene, on the site of an earlier foundation, 1542; Trinity, 1546 (absorbing several earlier foundations); Emmanuel, 1584; Sidney Sussex, 1588; Downing, 1800; Selwyn, 1882. Non-collegiate students possess a centre known as Fitzwilliam House.

Of the two women's colleges, Girton was established in 1873 and Newnham in 1875 (founded in 1873, as a hall of residence).

**Cambridge at the Renaissance and After.**—During the sixteenth century, the reputation of Cambridge grew steadily at the expense of Oxford. It claimed the Lady Margaret, Fisher and More as its patrons and officers, Erasmus, Cheke, Croke and Linacre as its teachers, and the New Learning found a more gracious welcome there than at Oxford. A little later it became the real centre of the Reformation in England, counting Bilney, Barnes, Tyndale, Cranmer and Bucer among its *alumni*. In the seventeenth century its reputation declined a little, its constitution became less liberal, its educational curriculum narrower. There was trouble with the town and trouble with the Puritans, even though Cambridge was something of a Puritan stronghold. But it recovered. By the end of the century it was the home of the Cambridge Platonists and of Sir Isaac Newton, Lucasian professor of mathematics from 1673 to 1702. It was favoured in the eighteenth century by the Hanoverian kings and by the duke of Newcastle as the Whig university, while the reputation of a man such as Bentley, master of Trinity, 1700–1742, proved that it still had scholars of merit. The first tripos, the mathematical, was established in the middle of the eighteenth century. In the early nineteenth century a wave of evangelicalism swept over Cambridge, comparable with, if less than, the Tractarian movement at Oxford.

During the same period the examinations were improved, written examinations were more and more employed and in 1824 the classical tripos was introduced. In 1858, the university was thrown open to dissenters who were allowed to take the B.A., and finally all tests were abolished in 1871. In 1877 further reforms were carried, one of which included the provisions for natural science. The effect of these reforms is shown from the fact that in 1862 the number of undergraduates was 1,526 and in 1887 2,979. A large number of colleges at home and abroad were affiliated to the university. From the later half of the 19th century onwards a series of new triposes were created: moral science (1851), natural

science (1851), theological (1856, examination theological tripos since 1874), law (1857, previously there had been civil law classes since 1816), Semitic language (1878, since 1895 Oriental languages), history (1875), Indian languages (1879), mediaeval and modern languages (1886), mechanical science (engineering, 1894), economics (1905) and most of the triposes were divided into two parts. A similar growth in the university professoriate took place. New creations were made in archaeology, divinity (Hulsean), pure mathematics, political economy, zoology, Sanskrit, international law, Latin, fine arts, experimental physics, mechanics and applied science, Anglo-Saxon, ecclesiastical history, physiology, pathology, divinity (Ely), mental philosophy and logic, Chinese, ancient history, agriculture, biology, agricultural botany, astrophysics, German, English literature, genetics. Readerships and college lectureships showed a like increase. A large number of important and often beautiful buildings were added to the university, increasing in the majority of cases the provision for scientific laboratory study. Among the more important are the famous Cavendish laboratory for physical research (1874), the chemical laboratory (1887), the law library erected from funds given in 1898 by Miss R. F. Squire, and the Sedgwick Geological museum (opened 1904).

**War Period.**—This period marks in one sense a stage of great moment in the history of the university. Sixteen thousand members of the university were engaged on active service; the contributions in research, invention, technical advice of every kind, rendered by the university, extended over the entire range of the activities provoked by the war over the whole of the British Empire; the university itself was empty of students and teachers; their places were taken for the time being by cadets, instructors, military staffs and troops, and to some extent by refugees, mainly from Belgium. Never, presumably, in the history of the university was the co-operation between university and State so close, so intense or so fruitful, not without leaving permanent traces on the development of the university during the post-war period. At the same time, few phenomena of social life, after the conclusion of the war, are so impressive as the ease and rapidity with which the historic traditions of the university, in teaching, in social intercourse, in collegiate life, were resumed.

The immediate effect of the conclusion of peace was a very great increase in the number of students, temporarily swelled in addition by the presence of over 1,500 men whose education had been interrupted by the war; assisted by Government grants, they were enabled to complete their courses by coming into residence for one, two, or in some cases three years. But the considerable increase (about 75%) in the number of students over pre-war numbers, which has continued even after 1922, would seem to be one of the several permanent features of the post-war history of the university, due to many causes such as the wide-spread redistribution of wealth in the country, the increase in facilities provided for education and the enhanced prestige of university training, both generally and professionally.

Meanwhile within the university one of the most outstanding events was the admission in 1923 of women to degrees but not to full membership of the body academic. In addition, the courses of study for honours, and more especially for pass men, underwent considerable revision. Greek, as a compulsory subject, was dropped from, and other noteworthy changes were effected in, the previous examination (1919); the regulations governing the pass degree were entirely remodelled (1920); several of the honours examinations, notably the classical tripos and the oriental languages tripos, were reconstituted with a division into two parts, the first of which does not normally carry the B.A. degree with it. New triposes were established in anthropology (1913) and geography (1919), while the mediaeval and modern languages tripos, greatly enlarged in scope and endowed with benefactions for Spanish and Scandinavian studies, was split into the modern and mediaeval languages tripos and the English tripos (1917). The university further recognized the value of graduate studies by establishing the degrees of Ph.D. (1919) and of M.Litt. and M.Sc. (1920).

New professorships, readerships and boards of studies were

established beyond pre-war additions which have been listed above such as the professorships of Italian (1919), naval history (1919), French (1919), physics (1919), aeronautical engineering (1919), physical chemistry (1920), biochemistry (1921), animal pathology (1923), political science (1927); readerships in Spanish, modern history, geography, agriculture, agricultural physiology, physiology, morphology of vertebrates, petrology, pharmacology, electrical engineering, geodesy, biochemistry, preventive medicine and experimental psychology.

Aids to learning and research of a more material nature were provided by the erection of numerous new institutes or the extension of existing laboratories. The engineering laboratory on the north side of Downing street was twice enlarged and finally removed to a completely new site behind Scroope terrace, Trumpington road (1920-21). Part of the buildings thereby vacated, as well as new buildings erected close to them, were taken over by the neighbouring chemical laboratories. On the south side of Downing street sites had been found for the School of Agriculture (1910), which was further enlarged 1926-27, for the Museum of Archaeology and Ethnology (1910-15), the Psychological laboratory (1913), the Physiological laboratory (1914), the Forestry school (1914); the Molteno Institute of Animal Parasitology (1921), a low temperature station for research in biochemistry and biophysics (1922), the Sir William Dunn School of Biochemistry (1924) and the new Pathological laboratory (1928) form imposing additions to the institutes on the same Downing street site. The Examination Hall and the Arts school, off Benet street, a fine brick building faced with stone, designed by G. Hubbard, which contains a number of lecture-rooms and also houses several departmental libraries, dates back to 1911. In that year the university had accepted the Government's proposal to take charge of the Solar Physics observatory, then at South Kensington, and the necessary accommodation, in close proximity to the existing observatory on the Madingley road, was completed in 1913. Field laboratories in connection with the agricultural and other departments on the Milton road came into use in 1910-11. An important and handsome addition to the university buildings was Stuart House, the seat of the new "Board of extra-mural studies" (opened in 1927). In 1924 the university purchased further estate for an eventual extension of the Fitzwilliam museum: a gallery leading to the projected addition was built and opened in 1925 for the temporary housing of the "Marlay Bequest" and one side of the quadrangle which is ultimately to form the extension of the museum, has been so far erected (1928). In 1925 the university also bought the "Lensfield House" estate, for the building of further institutes; "Lensfield House" itself houses the "Captain Scott Polar Research Institute" (founded 1925) and an extension of the university school of architecture, which since 1923 also occupies No. 1, Scroope terrace. Another important site has been secured by the university in the "Backs" for the erection of the new university library.

Emmanuel, Queens', Sidney Sussex, Clare, King's and Jesus colleges and Peterhouse added to their fabric and the chapels of Sidney Sussex and Corpus Christi colleges were enlarged and re-decorated. Wesley house, a post-graduate theological college for the training of accepted candidates for the ministry of the Wesleyan Methodist Church, was opened in 1925; and Cheshunt college, a theological seminary which was removed from Cheshunt to Cambridge in 1905, found permanent quarters at the end of Bateman street (1915).

The most serious after-effect of the war on the university, in addition to straining its resources and accommodation as well as its teaching powers to the utmost by the increased numbers of its students, was its financial position due to the serious rise in the cost of living and the depreciation in the value of money. Before the war and up to 1919 the university had never received any State aid, apart from small subventions of certain departments, like Agriculture or Medicine. But in 1919 the university was faced with the alternative of a considerable deficit or a reduction of its educational efficacy, and decided to apply to the Government for an annual grant. The result was the appointment of a royal commission, the first since 1877, to carry out "a comprehensive

enquiry into the resources of the university and colleges and the uses made of them"; until the commission should be in a position to report, the Government made an annual grant of £3,000 without prejudice to any eventual decision reached as the result of the enquiry. While abstaining from interference with teaching or curricula, the commission were bound to comprise in their enquiry also matters of administration and government of the university. The report of the commission, presented in 1922, is a most interesting document, giving an historical survey of the universities of Oxford and Cambridge, a review of the present situation of the two universities and a detailed statement of the commission's recommendations. In 1922 a statutory commission was created to carry the recommendations into effect.

The main burden of the recommendations may be summarized as aiming (a) to effect a closer co-operation between the university and the colleges financially (revised system of college taxation; adjustment of university and college salaries, etc.); (b) to unify and centralize university finance; (c) to increase the number and to improve the status of university lecturers and demonstrators; (d) to introduce a pension scheme for university teachers; (e) to increase the accessibility of the university by a revision of the scholarship system, and to improve the provision made for research students, etc.; (f) to introduce certain changes in the administration of the university (such as the creation of a regent house) in order to simplify legislative machinery for the internal government of the university; and (g) to secure an annual grant (which was in 1925 fixed at £85,000).

The period from 1922 to 1927 saw the introduction of most of the changes decided on by the statutory commissioners, including the recasting of college statutes to bring them into harmony with the changes in university administration. It was a time of intense activity, carried on in the most friendly spirit of collaboration between the statutory commissioners, the university and the colleges, and destined to mark the beginning of a new era in the history of the university. Enjoying more than ever public confidence, fuller than ever, with a constantly increasing pressure of applicants for admission, advancing into the ever widening fields of study and research, more than ever generous in help to merit and intelligence, the university, as always conscious of its tradition, has also adapted itself to the exigencies of the new situation, created by post-war conditions, and to the call of further educational progress.

**University Constitution and Administration.**—The university is a corporate body, including all the colleges. These, however, are also corporations in themselves, and have their own statutes, but they are further subject to the paramount laws of the university. The head of the university is the chancellor. He is a member of the university, elected by the senate for life. The vice-chancellor, who is the head of a college, is elected for one year by the senate. The proctors (*q.v.*) have as their main duty that of disciplinary officers over the members of the university *in statu pupillari*. The public orator is the spokesman of the senate upon such public occasions as the conferring of honorary degrees. The librarian has charge of the university library. The registry records the proceedings of the senate, etc., and has charge of documents. The assistant registrars act as secretaries to various boards. The treasurer is secretary to the financial board.

The senate in congregation is the legislative body. Those who have votes in it are the chancellor, vice-chancellor, doctors of divinity, law, medicine, science, letters and music, and masters of art, law, surgery and music. The council of the senate, consisting of the chancellor, vice-chancellor and sixteen members of the regent house, brings all proposals (called "graces") before the regent house or senate. The senate is the legislative body but the majority of its business is done by the regent house, the senate only acting as a court of appeal. The regent house consists of burgesses, university officers, heads of houses, members and secretaries of faculties, boards and syndicates and all fellows. The revenues of the university are derived chiefly from fees at matriculation, for certain examinations, and for degrees, from a tax upon all members of the university, and from con-

tributions by the colleges. A board, consisting of the vice-chancellor *ex officio* and certain elected members, administers the finances of the university. There are boards for each of the various faculties, and a General Board of Studies, with the vice-chancellor at the head. There are 60 professors, 27 readers, the total staff with lecturers, demonstrators and teachers amounting to about 250. The oldest professorship is the Lady Margaret professorship of divinity, instituted by the founders of Christ's and St. John's colleges in 1502.

The head of a college generally bears the title of master. The foundation of each college includes a certain number of fellows and scholars. The affairs of the college are managed by a college council of the head and the fellows. The scholars and other members *in statu pupillari* are termed undergraduates. Those who receive no emoluments (and therefore pay the full fees) form the bulk of the undergraduates. As regards his work, the undergraduate is under a director of studies; the disciplinary officer in college is the dean.

The total number of students is over 5,000. The colleges cannot accommodate this number, so that a student commonly spends some part of his residence in lodgings, which are licensed by, and under the control of, the university authorities. Such residence implies no sacrifice of membership of a college. There are three terms—Michaelmas (October), Lent and Easter (summer). They include together not less than 227 days, though the actual period of residence for undergraduates is about 24 weeks annually. Undergraduates usually begin residence in Michaelmas term. An elementary examination or other evidence of qualification is required for admission to a college. After nine terms' (three years') residence an undergraduate may take the first degree, that of bachelor of arts (B.A.). Students from affiliated colleges are allowed to present themselves for the first degree after a shortened period of residence. The examinations required for the ordinary B.A. degree are (1) Previous examination or "Little-go," or its equivalent to the School Certificate with five "credits," one necessarily in Latin; (2) examinations in the main subject; and evidence of study in three subordinate ones. Candidates for honours are required to have passed the Previous examination with certain additional subjects or the equivalent School Examination; they then take a tripos examination in one of the following subjects—mathematics, classics, moral sciences, natural sciences, theology, law, history, oriental languages, mediaeval and modern languages, mechanical sciences, economics, anthropology, English, geography and archaeology. The mathematical tripos is divided into two parts, in the second of which the candidates are classed in the result as Wranglers, Senior Optimes and Junior Optimes. The classical tripos is also in two parts, to the second of which certain kindred subjects are added (ancient philosophy, history, etc.); other triposes are similarly divided with three classes in each part. A pass in the first part of some triposes does not ensure a degree and the candidate is obliged to take a further examination. The university also awards a certain number of diplomas in agriculture, etc., and also certificates in French, as well as research degrees which require one or two years of residence.

**BIBLIOGRAPHY.**—For details of the administration of the university and colleges, regulations as to studies, prizes, scholarships, etc., see the annual *Cambridge University Calendar* and *The Students' Handbook to the University and Colleges of Cambridge*; see also R. Willis and J. W. Clark, *Architectural History of the University of Cambridge* (3 vols., Cambridge, 1886); J. Bass Mullinger, *History of the University of Cambridge from the Earliest Times to the Accession of Charles I.* (2 vols., 1873–84; third vol., 1909); *Report of Oxford and Cambridge University Commission* (1922). (E. Br.; G. R. P.)

**CAMBUSLANG**, town and parish, Lanarkshire, Scotland. It is situated near the Clyde, 4½ m. S.E. of Glasgow (of which it is a residential suburb) by the L.M.S.R. Pop. (1931) 27,128. Its leading industry is coal-mining, and it contains one of the largest steel works in Great Britain. It was the birthplace of John Claudius London (1783–1843), the landscape gardener and writer on horticulture.

**CAMBYSES** (Pers. *Kambujiya*), the name borne by the father and by the son of Cyrus the Great. When Cyrus conquered

Babylon in 539 B.C. he was employed in leading religious ceremonies (*Chronicle of Nabonidus*), and in the cylinder which contains Cyrus's proclamation to the Babylonians his name is joined with his father's in the prayers to Marduk. On a tablet dated from the first year of Cyrus, Cambyses is called king of Babel, but in reality it was only in 530 that Cyrus associated Cambyses with him on the throne, and numerous Babylonian tablets of this time are dated from the first year of Cambyses, when Cyrus was "king of the countries" (*i.e.*, of the world). After the death of his father in 528 Cambyses became sole king.

The traditions about Cambyses, preserved by Greek authors, come from two sources. The first, forming the main account of Herodotus (iii. 2; 4; 10-37), is of Egyptian origin. Here Cambyses is the son of Cyrus and a daughter of Apries (Herod. iii. 2, Dinon fr. II., Polyæn. viii. 29), whose death he avenges on the successor of the usurper Amasis. (In Herod. iii. I. and Ctesias *ap.* Athen. xiii. 560 D, this tradition is corrected by the Persians: Cambyses wants to marry a daughter of Amasis, who sends him instead a daughter of Apries, and by her Cambyses is led into war.) His great crime is the killing of the Apis, for which he is punished by madness.

In the Persian tradition the chief crime of Cambyses is the murder of his brother. With the exception of Babylonian dated tablets and some Egyptian inscriptions we possess no contemporary evidence for Cambyses except the short account of Darius in the Behistun inscription. Without doubt, he seems to have been a wild despot, committing many atrocities in his drunkenness.

Cyrus having conquered Asia, Cambyses undertook the conquest of Egypt, the only remaining independent State of the Eastern world. The war took place in 525, when Amasis had just been succeeded by his son Psammetichus III. The Persians, being supported by the Cyprian towns and the tyrant Polycrates of Samos, who possessed a large fleet, and the commander of the Greek troops, Phanes of Halicarnassus, defeated the Egyptians at Pelusium, and shortly afterwards Memphis was taken. The captive king Psammetichus was executed, having attempted a rebellion. From Egypt Cambyses attempted the conquest of Ethiopia (Cush), *i.e.*, the kingdom of Napata and Meroe, the modern Nubia, but the deserts forced him to return. In an inscription from Napata (in the Berlin museum) the Ethiopian king Nastesen relates that he had beaten the troops of Kembasuden, *i.e.* Cambyses, and taken all his ships (H. Schäfer, *Die Äthiopische Königsinschrift des Berliner Museums*, 1901). The plan of attacking Carthage was frustrated by the refusal of the Phoenicians to operate against their kindred. Meanwhile the Persian usurper, the Magian Gaumata, who in 522 pretended to be Cambyses's murdered brother, Bardiya (Smerdis), was acknowledged throughout Asia. After an unsuccessful march against him, Cambyses died by his own hand (March 521) according to the preferable account of Darius though the traditions of Herodotus and Ctesias ascribe his death to an accident.

Lincke, *Kambyses in der Sage, Literatur und Kunst des Mittelalters*, in *Aegyptiaca: Festschrift für Georg Ebers* (Leipzig, 1897), pp. 41-61; Strassmaier: *Inscriptionen von Cambyses*, No. 97; E. Meyer: *Gesch. der Altertums*, 3rd ed. (Berlin, 1921); J. V. Prásek: *Gesch. der Meder und Perser* (Gotha, 1906); and "Kambyses" in *Der Alte Oriente* (1913); also PERSIA: *Ancient History*.

**CAMDEN, CHARLES PRATT**, 1ST EARL (1714-1794), lord chancellor of England, was born in Kensington in 1714. He was a descendant of an old Devonshire family, the third son of Sir John Pratt, chief-justice of the king's bench in the reign of George I. He was educated at Eton and King's college, Cambridge. In 1734 he became a fellow of his college, and in the following year obtained his degree of B.A. He entered the Middle Temple in 1738, and ten years later he was called to the bar. He practised at first in the courts of common law, travelling also the western circuit.

The first case which brought him into notice was his successful defence of a bookseller on a charge of libel. In this case he first maintained the principle for which he fought all his life, that in libel the jury is judge both of law and fact. He was appointed attorney general in 1787 and the same year entered the House of

Commons as member for Downton in Wiltshire, sitting there for four years. One of the most noticeable incidents of his tenure of office as attorney-general was the prosecution of Dr. J. Shebbeare (1709-88), a violent party writer of the day, for a libel against the government contained in his notorious *Letters to the People of England*, which were published in the years 1756-58. This, in a period when State Trials were the chief weapon of party warfare, was the only official prosecution for libel he set on foot. In Jan. 1762 Pratt was raised to the bench as chief-justice of the common pleas. He was at the same time knighted. Soon after his elevation the nation was thrown into great excitement about the prosecution of John Wilkes, and the question involved in it of the legality of "general warrants." Chief-Justice Pratt pronounced, with decisive and almost passionate energy, against their legality, thus giving voice to the strong feeling of the nation and winning for himself an extraordinary degree of popularity in the country. In July 1765 he was raised to the peerage as Baron Camden, of Camden Place, in the county of Kent; and in the following year he was made lord chancellor (July 30, 1766). But though his excellence as a judge was such that only one of his decisions was reversed on appeal, his uncompromising hostility to the governments of the day on such questions as the treatment of the American colonies and the proceedings against Wilkes forced the government to ask him to resign. He retired from the court of chancery in Jan. 1770. He continued steadfastly to oppose the taxation of the American colonists, and signed in 1778, the protest of the Lords in favour of an address to the king on the subject of the manifesto of the commissioners to America. In 1782 he was appointed president of the council under the Rockingham administration, but retired in the following year. Within a few months he was reinstated in this office under the Pitt administration, and held it till his death. Lord Camden was a strenuous opponent of Fox's India Bill, took an animated part in the debates on important public matters till within two years of his death, introduced in 1786 the scheme of a regency on occasion of the king's insanity, and defended zealously and at last successfully his early views on the functions of juries, especially of their right to decide on all questions of libel. He was raised to the dignity of an earl in May 1786, and was at the same time created Viscount Bayham. Earl Camden died in London, on April 18, 1794. He was buried in Seale church, Kent.

See E. Foss, *Judges of England*, vol. viii. p. 375 (1848-64).

**CAMDEN, JOHN JEFFREYS PRATT**, 2ND EARL and 1ST MARQUESS (1759-1840), only son of the 1st earl, was born on Feb. 11, 1759, and was educated at Trinity College, Cambridge. In the ministry of William Pitt, Pratt, who entered parliament as M.P. for Bath in 1780, was successively a lord of the admiralty and a lord of the treasury; then, having succeeded his father in the earldom in 1794, he was appointed lord-lieutenant of Ireland in 1795. Disliked in Ireland as an opponent of Roman Catholic emancipation, and as the exponent of an unpopular policy, Camden's term of office was one of commotion and alarm, culminating in the rebellion of 1798. Immediately after the suppression of the rising he resigned, and in 1804 became secretary for war and the colonies under Pitt, and in 1805 lord president of the council. He was again lord president from 1807-12, after which date he remained for some time in the cabinet without office. In 1812 he was created earl of Brecknock and Marquess Camden. He died on Oct. 8, 1840.

**CAMDEN, WILLIAM** (1551-1623), English antiquary and historian, was born in London. His father, Sampson Camden, was a member of the company of painter-stainers. Young Camden received his early education at Christ's Hospital and St. Paul's school, and in 1566 went to Magdalen college, Oxford, probably as a servitor or chorister. He afterwards removed to Broadgates hall (Pembroke college), and later to Christ Church, where he was supported by his friend, Dr. Thomas Thornton, canon of Christ Church. In 1571 he went to London and devoted himself to antiquarian studies, for which he had already acquired a taste.

Camden spent some time in travelling in various parts of England collecting materials for his *Britannia, sive florentissimarum regnorum Angliae, Scotiae, Hiberniae et insularum adjacentium*

*ex intima antiquitate chorographica Descriptio*, first published in 1586. He became second master of Westminster school in 1575, and succeeded Dr. Edward Grant as headmaster in 1593. During the vacations he travelled, and supervised the publication of three further editions of the *Britannia*. Although a layman he was granted the prebend of Ilfracombe in 1589, and in 1597 he resigned his position at Westminster on being made Clarenceux king-of-arms an appointment which caused some ill-feeling. The York herald, Ralph Brooke, led an attack on the genealogical accuracy of the *Britannia*, and accused its author of plagiarism. Camden replied to Brooke in an appendix to the fifth edition of the *Britannia*, published in 1600. Having brought out an enlarged and improved edition of the *Britannia* in 1607, he began to work on a history of the reign of Queen Elizabeth, which he had been urged to undertake by Lord Burghley in 1597. The first part of this history dealing with the reign down to 1588, was published in 1615 under the title *Annales rerum Anglicarum et Hibernicarum regnante Elizabetha*. Controversy at once arose over the author's treatment of Mary, Queen of Scots. It was asserted that Camden altered his original narrative in order to please James I., and, moreover, that the account which he is said to have given to his friend, the French historian, Jacques de Thou, differed substantially from his own. It seems doubtful if there is any truth in either of these charges. The second part of his work, finished in 1617, was published at Leyden in 1625 and in London in 1627. Selden spoke of the *Annales* and of Bacon's *History of Henry VII.* as the only two serious works on English history up to his day. In 1622 Camden founded the chair at Oxford known as the Camden professorship of ancient history, the first occupant of which was his friend, Degory Wheare. His later years were mainly spent at Chislehurst, where he had gone to live in 1609, and in spite of recurring illnesses he continued his antiquarian and historical studies. He died at Chislehurst on Nov. 9, 1623.

Camden, who refused a knighthood, was a man of enormous industry, and of a modest and friendly disposition. He had a large number of influential friends, among whom were Archbishop Ussher, Sir Robert Cotton, John Selden, the French jurist Brisson, and Isaac Casaubon. His correspondence was published in London in 1691 by Dr. Thomas Smith under the title *Vita Gulielmi Camdeni et Illustrium virorum ad G. Camdenum Epistolae* which, together with the notices in Bayle's *Dictionary* and in Wood's *Athenae Oxonienses*, is the chief authority for his biography. This volume contains Camden's *Memorabilia de seipso*; his notes of the reign of James I.; and other interesting matter. In 1838 the Camden Society was founded in his honour, and much valuable work has been done under its auspices.

**BIBLIOGRAPHY.**—The *Britannia* was first translated into English by Philemon Holland, in 1610, probably under the author's direction, and other translations have subsequently appeared, the best of which is an edition edited by Richard Gough and published in 3 vols. in 1789, and in 4 vols. in 1806. The best edition of the *Annales* is by Thomas Hearne (1717). The book was translated into French, and English translations appeared in 1635, 1675 and 1688. In addition to these works Camden compiled a Greek grammar, *Institutio Graecae Grammatices Compendiaria*, which became very popular, and he published an edition of the writings of Asser, Giraldus Cambrensis, Thomas Walsingham and others, under the title *Anglica, Hibernica, Normannica, Cambrica, a veteribus scripta*, (1602 and 1603). He also drew up a list of the epitaphs in Westminster Abbey, which was issued as *Reges, Reginae, Nobiles et alii in ecclesia collegiata Beati Petri Westmonasterii sepulti*. This was enlarged and published again in 1603 and 1606. In 1605 he published his *Remains concerning Britain*, a book of collections from the *Britannia*, which quickly passed through seven editions; and he wrote an official account of the trial of the Gunpowder Plot conspirators as *Actio in Henricum Garnetum, Societatis Jesuiticae in Anglia superiorem et caeteros*.

**CAMDEN**, a city of New Jersey, U.S.A., the county seat of Camden county, on the Delaware river, opposite Philadelphia, with which it is connected by a suspension bridge (opened 1926) which is 8,126ft. long, 135ft. above the water, and has a span of 1,750 feet. It is on Federal highways 30 and 130, and is served by the Pennsylvania and the Reading railways. The land area is 7.75sq. miles. The population in 1920 was 116,309, of whom 20,262 were foreign-born white and 8,500 were negroes; and was 118,700 in 1930 by Federal census.

The city has a water-front of 6.1m. on the Delaware and 6.2 along the Cooper river, which divides it into East and West Camden. A municipal pier with a floor area of 33,636sq.ft. was built in 1920–21. A civic centre was being developed in 1928 as part of a comprehensive city plan. Bus and electric lines are co-ordinated in a unified service, operating out of a common terminal. The water supply is derived from 136 artesian wells, with a flow of 36,000,000gal. a day. The city has a commission form of government (adopted 1923). The assessed valuation of property in 1927 was \$195,153,306.

The manufacturing industries are numerous and important, with a varied output ranging from pen-points to battleships. The aggregate output in 1925 was valued at \$164,050,849. Among the products manufactured are: steel pens, talking-machines, canned soups, and oilcloth and linoleum. During the World War the New York Shipbuilding Corporation delivered more ships than any other yard in the country, and made a record for rapid construction in the collier "Tuckahoe," which was launched on the 27th day after work was begun on her keel. There has never been a bank failure in Camden. Clearings in 1926 amounted to \$771,000,000.

The early settlers were largely Quakers. William Cooper in 1681 built a home just below the mouth of the Cooper river, and called it Pyne Poynt. For a century the settlement consisted of a little group of houses around the ferry. In 1773 Jacob Cooper, a descendant of William, laid out a town, and named it after Lord Chancellor Camden, one of the strongest opponents of the Stamp Act. Until 1828, when Camden was incorporated, with a population of 1,143, it was a part of the town of Newton, Gloucester county. During the British occupation of Philadelphia in the Revolutionary War a British force was stationed in Camden, and it was the scene of several skirmishes. Camden was the home of Walt Whitman from 1873 until his death. He was buried in Harley cemetery, and his house in Mickle street is kept as a memorial.

**CAMDEN**, a city of South Carolina, U.S.A., 30 m. N.E. of Columbia, near the Wateree river; the county seat of Kershaw county. It is on Federal highway 1 and is served by the Atlantic Coast Line, the Seaboard Air Line and the Southern railways. The population in 1920 was 3,930 (47% negroes); in 1930 it was 5,183. It is a winter resort, in the heart of the long-leaf pine region. There are many examples of colonial architecture, including the old court-house, which is now a museum. The city has a hydro-electric power plant and several factories. It was settled in 1758 and incorporated in 1791.

For a year during the Revolution, Camden was the centre of important military operations. It was occupied by the British under Cornwallis in June 1780, was well fortified and was garrisoned by a force under Lord Rawdon. On Aug. 16, Gen. Horatio Gates, with an American force of about 3,600, including some Virginia militia under Charles Porterfield and Gen. Edward Stevens, and North Carolina militia under Gen. Richard Caswell, was defeated here by the British, about 2,000 strong, under Lord Cornwallis, who had joined Rawdon in anticipation of an attack by Gates. Soon after the engagement began a large part of the Americans, mostly North Carolina and Virginia militia, fled precipitately, carrying Gates with them; but Baron De Kalb and the Maryland troops fought bravely until overwhelmed by numbers, De Kalb himself being mortally wounded. A monument was erected to his memory in 1825, Lafayette laying the corner-stone. The British loss in killed, wounded and missing was 324; the American loss was about 800 or 900 killed and 1,000 prisoners, besides arms and baggage. On Dec. 3, Gates was superseded by Greene, who after Cornwallis had left the Carolinas, advanced on Camden and arrived in the neighbourhood on April 19, 1781. Considering his force (about 1,450) insufficient for an attack on the fortifications, he withdrew a short distance north of Camden to an advantageous position on Hobkirk's Hill, where on April 25, Rawdon, with a force of only 950, took him somewhat by surprise and drove him from the field. The casualties on each side were nearly equal: American 271; British 258. On May 8, Rawdon evacuated the town, after burning most of it. On Feb. 24, 1865, during the Civil War, a part of Gen. Sherman's army entered Camden and burned stores of tobacco and cotton. (See AMERICAN REVOLUTION.)

See also T. J. Kirkland and R. M. Kennedy, *Historic Camden* (Columbia (S.C.), 1905).

**CAMEL**, the name applied to the two species of the genus *Camelus* of the order Artiodactyla (*q.v.*). Of the two species, *C. dromedarius*, the Arabian camel, is larger and has only one hump, while the Bactrian camel, *C. bactrianus*, has two. The Bactrian camel is shorter legged and more ponderous and grows a long, thick winter coat, which it sheds in masses in the spring. Its native home is central Asia, where it occurs in a wild state in the deserts of eastern Turkistan between the Altyn-tagh mountains and the Tarim river. The wild form, however, differs in several respects from the domestic breed, and is more similar in many ways to the fossil *C. knoblochi* from Russia and *C. alutensis* from Rumania. The domestic variety of *C. bactrianus* is the most important beast of burden in eastern Turkistan and Mongolia.

The Arabian camel is unknown in the wild state and is evidently one of the oldest of domestic animals. It will carry a load of 500 to 1,000 lb. 25 miles a day for three days without drinking. This and similar feats are rendered possible by the peculiar formation of the stomach of both species (*see* PECORA). The widespread, soft feet are admirably adapted for walking on yielding sand.

During the rutting season the male camel is very savage, uttering a loud bubbling roar and fighting fiercely with its fellows. The tameness of the camel is essentially the tameness of stupidity. Sir F. Palgrave writes, "He is from first to last an undomesticated and savage animal, rendered serviceable by stupidity alone, without much skill on his master's part or any co-operation on his own, save that of an extreme passiveness. Neither attachment nor even habit impress him; never tame, though not wide-awake enough to be exactly wild."

The food of the camel consists of the leaves of trees and shrubs. The female produces one young at a birth, after 11 months' gestation. The mother suckles her offspring for a year and the latter does not reach maturity until its sixteenth or seventeenth year, living until it is forty or fifty. (*See* TYLOPODA.)

**CAMEL CORPS**, a military unit mounted on camels for service in the desert. The first Egyptian camel corps was formed in 1884 for the Gordon relief expedition, the personnel being drawn from British units; it was disbanded at the conclusion of the campaign. Later a new camel corps was recruited from Sudanese and Egyptian sources, and became a permanent part of the Egyptian army; it fought with credit in the campaigns against the Khalifa between 1896 and 1898. It now numbers about 1,100 strong and forms part of the Sudan defence force. The Bikanir Camel Corps is an imperial service unit raised and maintained by the maharaja of Bikanir, one of the native princes of India. It has seen much active service, taking part, without its camels, in the China expedition of 1900, and in the operations in Somaliland in 1903-04. When the World War broke out, it again volunteered to go overseas, and did valuable work in Egypt. The establishment of the corps, which is recruited on the Silladar system, is some 500 of all ranks. An imperial camel corps brigade, a composite British, Australian and New Zealand formation, served in Palestine from 1917 to June 1918, when it was reorganized as cavalry. It played a creditable part in the battles of Romani and Gaza, and shared in the attack on Beersheba and the subsequent advance to Jerusalem as well as in the Amman and Es Salt raids.

**CAMELLIA**, a genus of evergreen trees or shrubs belonging to the family Theaceae, with thick, dark shining leaves and

BY COURTESY OF THE NEW YORK ZOOLOGICAL SOCIETY

THE BACTRIAN CAMEL

BY COURTESY OF THE NEW YORK ZOOLOGICAL SOCIETY

THE DROMEDARY (ARABIAN) CAMEL

handsome white or rose-coloured flowers. It contains about eight species, natives of India, China and Japan. Most of the numerous cultivated forms are horticultural products of *C. japonica*, a native of China and Japan. The wild plant has red flowers, recalling those of the wild rose, but most of the cultivated forms are double. In the variety *anemonaeflora* nearly all the stamens have become transformed into small petaloid structures, which give the flower the appearance of a double anemone. Another species, *C. reticulata*, a native of Hongkong, is also prized for its handsome flowers, larger than those of *C. japonica*, which are of a bright rose colour. Both *C. sasanqua* and *C. drupifera*, the former inhabiting Japan and China, the latter Cochin-China and the mountains of India, are oil-yielding plants. The oil of *C. Sasanqua* has an agreeable odour and is used for many domestic purposes. It is obtained from the seeds, the leaves in a dried state are mixed with tea on account of their pleasant flavour. The oil of *C. drupifera*, which is closely allied to *C. Sasanqua*, is used medicinally in Cochin-China. The flowers of these two species, unlike those of *C. japonica* and *C. reticulata*, are odoriferous.

Camellias, though generally grown in the cool greenhouse, are hardy in the south of England and the south-west of Scotland and Ireland and mild districts in the United States. They grow best in a rich compost of sandy peat and loam, and a liberal supply of water is necessary.

**CAMELOT**, the legendary seat of King Arthur's court (*see* ARTHURIAN LEGEND), variously identified with Caerleon-upon-Usk in Monmouthshire (*see* CAERLEON), with Queen's Camel in Somerset, with the little town of Camelford in Cornwall and with Winchester.

**CAMEO**, a term commonly applied to engraved work executed in relief on hard or precious stones, as well as to imitations of such stones in glass, called "pastes," and on the shells of molluscous animals. The cameo is therefore the converse of the intaglio (*q.v.*), which consists of an incised or sunk engraving in the same class of materials. (*See* GEM and GEMS IN ART.)

**CAMERA**, in law, is applied, in the phrase *in camera*, to cases heard in private; that is, in chambers. Originally the term was used for the English judges' chambers in Serjeants' Inn, as distinct from their bench in Westminster Hall. It was afterwards applied to the judges' private room behind the court.

It has been said by Lord St. Heliers, Lord Haldane and Lord Reading that, given proper circumstances, there is an inherent right in all courts to sit *in camera*. In the chancery courts this has been the practice in cases affecting wards of court, lunatics, family disputes, and where a public trial would defeat the object of the action. The court of appeal has also exercised the right to sit *in camera* in a patent case involving a secret process. Under the Matrimonial Causes Act, 1857, nullity and judicial separation suits may be heard in private, and by the Children Act, 1908, the Defence of the Realm Act, 1914, the Official Secrets Act, 1920, and the Adoption of Children Act, 1926, the courts are empowered to sit *in camera*. But apart from statutory provisions it is doubtful whether in civil or criminal proceedings the courts have power to sit in private or to order adults out of court. All cases tried under the Summary Jurisdiction Act, 1879, must be heard in open court, unless there is some statute to the contrary.

**CAMERA LUCIDA**, an optical instrument invented by Dr. William Hyde Wollaston for drawing in perspective. Closing one eye and looking vertically downwards with the other through a slip of plain glass, *e.g.*, a microscope cover-glass, held close to the eye and inclined at an angle of 45° to the horizon, one can see the images of objects in front, formed by reflection from the surface of the glass, and at the same time one can also see through the transparent glass. The virtual images of the objects appear projected on the surface of a sheet of paper placed beneath the slip of glass, and their outline can be accurately traced with a pencil. This is the simplest form of the camera lucida. The image (*see* fig. 1) is, however, inverted and changed from right to left and it is not very bright owing to the poor reflecting power of unsilvered glass. The brightness of the image is sometimes increased by silvering the glass; and on removing a small portion of the silver the observer can see the image with part of the

pupil while he sees the paper through the unsilvered aperture with the remaining part. This form of the instrument is often used in conjunction with the microscope, the mirror being attached to the eye-piece and the tube of the microscope being placed horizontally.

About the beginning of the 19th century Dr. Wollaston invented a simple form of the camera lucida which gives bright and erect images. A four-sided prism of glass is constructed having one angle of  $90^\circ$ , the opposite angle of  $135^\circ$ , and the two remaining angles each of  $67\frac{1}{2}^\circ$ . This is represented in cross-section and in position in fig. 2. When the pupil of the eye is held half over the edge of the prism *a*, one sees the image of the object with one half of the pupil and the paper with the other half. The image is formed by successive total reflection at the surfaces *b c* and *a b*. In the first place an inverted image (first image) is formed in the face *b c*, and then an image of this image is formed in *a b*, and it is the outline of this second image seen projected on the paper that is traced by the pencil. It is desirable for two reasons that the image should lie in the plane of the paper, and this can be secured by placing a suitable lens between the object and the prism. If the image does not lie in the plane of the paper, it is impossible to see it and the pencil-point clearly at the same time. Moreover, any slight movement of the head will cause the image to appear to move relatively to the paper, and will render it difficult to obtain an accurate drawing.

Before the application of photography, the camera lucida was of considerable importance to draughtsmen. The advantages claimed for it were its cheapness, smallness and portability; that there was no appreciable distortion, and that its field was much larger than that of the camera obscura. It was used largely for copying, for reducing or for enlarging existing drawings. It will readily be understood, for example, that a copy will be half-size if the distance of the object from the instrument is double the distance of the instrument from the copy. (C. J. J.)

**CAMERA OBSCURA**, an optical apparatus consisting of a darkened chamber (for which its name is the Latin rendering) into which light is admitted through a convex lens fixed in one end of the chamber. This lens forms an image of external objects on the other end of the camera (fig. 1). The end of the camera on which the image is formed, the screen, may be made of translucent paper or ground glass, in which case the image is viewed from outside the camera, or it may be an opaque surface, the camera being sufficiently large to allow the head and shoulders, or even the whole body of the observer to be introduced into the chamber, in which case the image is viewed from inside the camera. The image formed on the screen is a real or actual image, not virtual as in camera lucida (*q.v.*). Frequently a sloping mirror (fig. 2, *a*) or  $90^\circ$  prism (fig. 2, *b*) is added to the simple optical system; but more generally the mirror and lens are combined into a single piece of worked glass represented in section in fig. 3. Rays from external objects are first refracted at the convex surface *a b*, then totally reflected at the plane surface *a c*, and finally refracted at the surface *b c* so as to form an image on the sheet of paper *d e*. The curved surface takes the place of the lens in fig. 2, *a*, and the plane surface performs the function of the mirror. The prism *a b c* is fixed at the top of a small tent furnished with opaque curtains so as to prevent the diffused daylight from overpowering the image on the paper, and in the darkened tent the images of external objects are seen very distinctly.

CAMERA LUCIDA, AN OPTICAL INSTRUMENT FOR USE IN DRAWING IN PERSPECTIVE

FIG. 1.—Simple form using thin glass plate held at an angle of  $45^\circ$   
FIG. 2.—Wollaston's four-sided prism

Other modifications of the optical system have been made (*see* PHOTOGRAPHY). The camera obscura has come into use with submarine vessels, the *periscope* (*q.v.*) being simply a camera obscura under a new name. The camera obscura was extensively used in sketching from nature before the introduction of photography.

**History.**—The invention of this instrument has generally been ascribed to Giovanni Battista della Porta, but the principle of the simple camera obscura, or darkened chamber with a small aperture in a window or shutter, was well known and in practical use for observing eclipses long before his time, and all he seems really to have done was to popularize it. From the opening passage of Euclid's *Optics* (*c.* 300 B.C.), it would appear that the phenomena of the simple darkened room were used by him to demonstrate the rectilinear propagation of light by the passage of sunbeams or the projection of the images of objects through small openings in windows, etc. In the book known as Aristotle's *Problems* (sect. xv. cap. 5) we find the correlated problem of the image of the sun passing through a quadrilateral aperture always appearing round, and Aristotle has further noted that the lunated image of the eclipsed sun projected in the same way through the interstices of foliage or lattice-work.

There are, however, very few allusions to these phenomena in the later classical Greek and Roman writers, and we find the first scientific investigation of them in the great optical treatise of the Arabian philosopher Alhazen (*q.v.*), who died at Cairo in A.D. 1038. He seems to have been well acquainted with the projection of images of objects through small apertures, and to have been the first to show that the arrival of the image of an object at the concave surface of the common nerve—or the retina—corresponds with the passage of light from an object through an aperture in a darkened place, from which it falls upon a surface facing the aperture. Some two hundred years later, between A.D. 1266 and 1279, these problems were taken up by three almost contemporaneous writers on optics, two of whom, Roger Bacon (*De Speculis and Perspectiva*) and John Peckham (*Perspectiva Communis*), were Englishmen, and Vitello or Witelo (*Optics*), who was known to have been of Polish extraction.

The first practical step towards the development of the camera obscura seems to have been made by the famous painter and architect, Leon Battista Alberti, in 1437, contemporaneously with the invention of printing. It is not clear, however, whether his invention was a camera obscura or a show box, but in a fragment of an anonymous biography of him, published in Muratori's *Rerum Italicarum Scriptores* (xxv. 296), quoted by Vasari, it is stated that he produced wonderfully painted pictures, which were exhibited by him in some sort of small closed box through a very small aperture, with great verisimilitude. These demonstrations were of two kinds, one nocturnal, showing the moon and bright stars, the other diurnal, for day scenes. This descrip-

The addition of optical appliances to the simple dark chamber

Thus the use of the camera and of the lens with it was well known before Porta published his second edition of the *Magia Naturalis* in 1589. In this the description of the camera obscura is in lib. xvii. cap. 6. The use of the convex lens, which is given as a great secret, in place of the concave speculum of the first edition, is not so clearly described as by Barbaro; the addition of the concave speculum is proposed for making the images larger and clearer, and also for making them erect, but no details are given. He describes some entertaining peep-show arrangements, possibly similar to Alberti's, and indicates how the dark chamber

FIG. 3.—CAMERA OBSCURA WITH LENS AND PRISM COMBINED

with a concave speculum can be used for observing eclipses. There is no mention whatever of a portable box or construction beyond the darkened room, nor is there in his later work, *De Refractione Optices Parte* (1593), in which he discusses the analogy between vision and the simple dark room with an aperture, but incorrectly. Though Porta's merits were undoubtedly great, he did not invent or improve the camera obscura. His only novelty was the use of it as a peep-show; his descriptions of it are vague, but being published in a book of general reference, which became popular, he acquired credit for the invention.

The first to take up the camera obscura after Porta was Kepler, who used it in the old way for solar observations in 1600, and in his *Ad Vitellionem Paralipomena* (1604) discusses the early problems of the passages of light through small apertures, and the rationale of the simple dark chamber. He was the first to describe an instrument fitted with a sight and paper screen for observing the diameters of the sun and moon in a dark room. In his later book, *Dioptrice* (1611), he fully discusses refraction and the use of lenses, showing the action of the double convex lens in the camera obscura, with the principles which regulate its use and the reason of the reversal of the image. He also demonstrates how enlarged images can be produced and projected on paper by using a concave lens at a suitable distance behind the convex, as in modern telephotographic lenses. He was the first to use the term *camera obscura*, and in a letter from Sir H. Wotton written to Lord Bacon in 1620 we learn that Kepler had made himself a portable dark tent fitted with a telescope lens and used for sketching landscapes. Further, he extended the work of Maurolycus, and demonstrated the exact analogy between the eye and the camera and the arrangement by which an inverted image is produced on the retina.

In 1609 the telescope came into use, and the danger of observing the sun with it was soon discovered. In 1611 Johann Fabricius published his observations of sun-spots and describes how he and his father fell back upon the old method of projecting the sun's image in a darkened room, finding that they could observe the spots just as well as with the telescope. They do not seem to have used a lens, or thought of using the telescope for projecting an enlarged image on Kepler's principle. This was done in 1612 by Christoph Scheiner, who fully described his method of solar observation in the *Rosa Ursina* (1630), demonstrating very clearly and practically the advantages and disadvantages of using the camera, without a lens, with a single convex lens, and with a telescopic combination of convex object-glass and concave enlarging lens, the last arrangement being mounted with an adjustable screen or tablet on an equatorial stand. Most of the earlier astronomical work was done in a darkened room, but here we first find the dark chamber constructed of wooden rods covered with cloth or paper, and used separately to screen the observing-tablet.

Various writers on optics in the 17th century discussed the principle of the simple dark chamber alone and with single or compound lenses, among them Jean Tarde (*Les Astres de Borbon*, 1623); Descartes, the pupil of Kepler (*Dioptrique*, 1637); Bettinus (*Apiaria*, 1645); A. Kircher (*Ars Magna Lucis et Umbrae*, 1646); J. Hevelius (*Selenographia*, 1647); Schott (*Magia Universalis Naturae et Artis*, 1674); C. F. M. Deschales (*Cursus, seu Mundus Mathematicus*, 1674); Z. Traber (*Nervus Opticus*, 1675), but their accounts are generally more interesting theoretically than as recording progress in the practical use and development of the instrument.

The earliest mention of the camera obscura in England is probably in Francis Bacon's *De Augmentis Scientiarum*, but it is only as an illustration of the projected images showing better on a white screen than on a black one. Sir H. Wotton's letter of 1620 was published in 1651 (*Reliquiae Wottonianae*, p. 141) and in 1658 a description of Kepler's portable tent camera for sketching, taken from it, was published in a work called *Graphice, or the most excellent Art of Painting*, but no mention is made of Kepler. In W. Oughtred's English edition (1633) of the *Récréations mathématiques* (1627) of Jean Leurechon ("Henry van Etten") there is a quaint description, with figures, of the simple dark chamber with aperture, and also of a sort of tent with a lens in it and the

projection on an inner wall of the face of a man standing outside. The English translation of Porta's *Natural Magick* was published in 1658.

Robert Boyle seems to have been the first to construct a box camera with lens for viewing landscapes. It is mentioned in his essay *On the Systematic or Cosmical Qualities of Things* (ch. vi.), written about 1570, as having been made several years before and since imitated and improved. It could be extended or shortened like a telescope. At one end of it paper was stretched, and at the other a convex lens was fitted in a hole, the image being viewed through an aperture at the top of the box. Robert Hooke, who was some time Boyle's assistant, described (*Phil. Trans.*, 1668, 3, p. 741) a camera lucida on the principle of the magic lantern, in which the images of illuminated and inverted objects were projected on any desired scale by means of a broad convex lens through an aperture into a room where they were viewed by the spectators. If the objects could not be inverted, another lens was used for erecting the images. From Hooke's *Posthumous Works* (1705), p. 127, we find that in one of the Cutlerian lectures on Light delivered in 1680, he illustrated the phenomena of vision by a darkened room, or perspective box, of a peculiar pattern, the back part, with a concave white screen at the end of it, being cylindrical and capable of being moved in and out, while the fore part was conical, a double convex lens being fixed in a hole in front. The image was viewed through a large hole in the side. It was between 4 and 5 ft. long.

Johann Zahn, in his *Oculus Artificialis Teledioptricus* (1685-1686) described and figured two forms of portable box cameras with lenses. One was a wooden box with a projecting tube in which a combination of a concave with a convex lens was fitted, for throwing an enlarged image upon the focusing screen, which in its proportions and application is very similar to our modern telephotographic objectives. The image was first thrown upon an inclined mirror and then reflected upwards to a paper screen on the top of the box. In an earlier form the image is thrown upon a vertical thin paper screen and viewed through a hole in the back of the camera.

Most of the writers already noticed worked out the problems connected with the projection of images in the camera obscura more by actual practice than by calculation, but William Molyneux, of Dublin, seems to have been the first to treat them mathematically in his *Dioptrica Nova* (1692), which was also the first work in English on the subject, and is otherwise an interesting book. He has fully discussed the optical theory of the dark chamber, with and without a lens, and its analogy to the eye. He does not, however, mention the camera obscura as an instrument in use, but in John Harris's *Lexicon Technicum* (1704) we find that the camera obscura with the arrangement called the "scioptric ball," and known as *sciopticks*, was on sale in London, and after this must have been in common use as a sketching instrument or as a show.

Sir Isaac Newton, in his *Opticks* (1704), explains the principle of the camera obscura with single convex lens and its analogy with vision in illustration of his seventh axiom, which aptly embodies the correct solution of Aristotle's old problem. He also made great use of the simple dark chamber for his optical experiments with prisms, etc. Joseph Priestley (1772) mentions the application of the solar microscope, both to the small and portable and the large camera obscura. Many patterns of these two forms for sketching and for viewing surrounding scenes are described in W. J. Gravesande's *Essai de perspective* (1711), Robert Smith's *Compleat System of Optics* (1738), Joseph Harris's *Treatise on Optics* (1775), Charles Hutton's *Philosophical and Mathematical Dictionary*, and other books on optics and physics of that period. The camera obscura was first applied to photography (*q.v.*) probably about 1794, by Thomas Wedgwood. His experiments with Sir Humphry Davy in endeavouring to fix the images of natural objects as seen in the camera were published in 1802.

**CAMERA, PHOTOGRAPHIC**, see PHOTOGRAPHY.

**CAMERARIUS, JOACHIM** (1500-1574), German classical scholar, was born at Bamberg on April 12, 1500. In 1530 he was sent as deputy for Nuremberg to the diet of Augsburg,

where he helped Melanchthon in drawing up the Confession of Augsburg. Five years later he was commissioned by Duke Ulrich of Württemberg to reorganize the university of Tübingen; and in 1541 he rendered a similar service at Leipzig, where he died on April 17, 1574. He played an important part in the Reformation movement, and his advice was sought by leading men. In 1535 he corresponded with Francis I. as to the possibility of a reconciliation between the Catholic and Protestant creeds; and in 1568 Maximilian II. sent for him to Vienna to consult him on the same subject. He translated into Latin Herodotus, Demosthenes, Xenophon, Homer, Theocritus, Sophocles, Lucian, Theodoretus, Nicephorus, and other Greek writers. He published upwards of 150 works, including a *Catalogue of the Bishops of the Principal Sees*; *Greek Epistles*; *Accounts of his Journeys*, in Latin verse; a commentary on Plautus; a treatise on Numismatics; *Euclid* in Latin; and the Lives of Helius Eobanus Hessus, George of Anhalt, and Philip Melanchthon. His *Epistolae Familiares* (published after his death) are a valuable contribution to the history of his time.

See article by A. Horawitz in *Allgemeine deutsche Biographie*; C. Bursian, *Die Geschichte der klassischen Philologie in Deutschland* (1883); J. E. Sandys, *Hist. Class. Schol.* (ed. 1908), ii. 266.

**CAMERARIUS, RUDOLF JAKOB** (1665–1721), German botanist and physician, was born in Tübingen on Feb. 12, 1665, and died there on Sept. 11, 1721. He became professor of medicine and director of the botanical gardens at Tübingen in 1687. He is chiefly known for his investigations on the reproductive organs of plants (*De sexu plantarum epistola*, 1694).

**CAMERINO** (anc. *Camerinum*), a city and episcopal see (since A.D. 465, if not earlier; Treia is now combined with it) of the Marches, Italy, in the province of Macerata, 6 m. S. of the railway station of Castelraimondo (to which there is an electric tramway) which is 24 m. W. of Macerata; 2,148 ft. above sea-level. Pop. (1921) of town, 4,328; of commune, 12,211. The cathedral is modern, the older building having fallen in 1799; the church of S. Venanzo suffered similarly, but preserves a portal of the 15th century. The citadel dates from 1502. There is a small university (about 500 students). Camerino occupies the site of the ancient Camerinum, the inhabitants of which (*Camertes Umbri*) became allies of the Romans in 310 B.C.

**CAMERON, DONALD:** see LOCHIEL.

**CAMERON, IRVING HEWARD** (1855– ), Canadian surgeon, son of Sir Matthew Crooks Cameron, one-time Chief Justice of the Common Pleas, was born in Toronto on July 17, 1855. He was educated at Upper Canada college and the University of Toronto of which he is Emeritus professor of Surgery. He founded and edited the *Canadian Journal of Medical Sciences*, and was formerly president of the Canadian Medical Association. He holds honorary fellowships of the Royal College of Surgeons (Edinburgh, Ireland and England) and is an honorary LL.D. of Edinburgh university.

**CAMERON, JOHN** (c. 1579–1625), Scottish theologian, born at Glasgow about 1579, received his early education in his native city. After having taught Greek in the university for 12 months, he went to France, where he lectured at Bordeaux and Sedan. He then travelled in Germany and Switzerland with the sons of Calignon, chancellor of Navarre, and in 1618, was appointed professor of divinity at Saumur, the principal seminary of the French Protestants.

In 1620 the civil troubles in France drove Cameron to England. In 1622 the king appointed him principal of the University of Glasgow in the room of Robert Boyd. Cameron was prepared to accept Episcopacy, and was cordially disliked for his adherence to the doctrine of passive obedience. He resigned his office in less than a year.

He returned to France, and there again made many enemies by his doctrine of passive obedience. He was stabbed in the street at Montauban in 1625, and died of the wound. His collected works, which were written some in French, some in Latin, were collected (in Latin) and published at Geneva in 1642, with a memoir by Cappel.

Cameron has a distinct place in the development of Calvinistic

theology. He and his followers maintained that the will of man is determined by the practical judgment of the mind; that the cause of men's doing good or evil proceeds from the knowledge which God infuses into them; and that God does not move the will physically, but only morally, by virtue of its dependence on the judgment of the mind. This peculiar doctrine of grace and free-will was adopted by Amyraut, Cappel, Bochart, Dailé and others of the more learned among the Reformed ministers, who dissented from Calvin's. The Cameronites (not to be confused with the Scottish sect called Cameronians) are moderate Calvinists, and approach to the opinion of the Arminians. They are also called Universalists, as holding the universal reference of Christ's death; and sometimes Amyraldists.

**CAMERON, RICHARD** (1648?–1680), founder of a Scottish religious sect of Cameronians, which formed the nucleus of the regiment of this name in the British army, was born at Falkland, Fife. He was the schoolmaster of his native village and then chaplain and tutor in the house of a Sir W. Scott of Harden. He was licensed as a field-preacher, and moved great crowds by his eloquence. With many others he sought refuge for a time in Holland, returning in 1680. He gathered together a small band of recalcitrants, among them David Cargill and Thomas Douglas, who issued the Sanquhar Declaration, calling for war against Charles II. and the exclusion of James, duke of York from the succession. A price was placed on the heads of Cameron and his chief supporters. On July 22, 1680, Cameron was slain in a skirmish at the Aird's, or Airds, Moss, fighting bravely at the head of the few troops which he had been able to collect. His prayer before going into battle became a tradition—"Lord spare the green and take the ripe." After the accession of William III. the survivors were amnestied, and the Cameronian regiment was formed from them.

See Herzog-Hauck, *Realencyklopädie* (1897), s.v. "Cameronianer"; Herkless, *Richard Cameron* (1897).

**CAMERON, SIMON** (1799–1889), American politician, was born in Lancaster county, Pa., on March 8, 1799. Left an orphan at the age of nine, he early entered journalism, and, in banking and railway enterprises, accumulated a considerable fortune. He became influential in Pennsylvania politics, and in 1845–49 served in the U.S. Senate, being elected by a combination of Democratic, Whig and "American" votes. In 1854 he became a leader of the "People's Party," as the Republican Party was at first called in Pennsylvania. In 1857 he was elected to the U.S. Senate as a Republican. His prominence as a candidate for the presidential nomination in the Republican national convention of 1860 led to his being selected by President Lincoln as secretary of war. His administration of this office at a critical time was marked by his accustomed energy, but unfortunately also by partiality in the letting of Government contracts, which brought about his resignation at Lincoln's request in Jan. 1862 and his subsequent censure by the House of Representatives. He again served in the Senate from 1867 until 1877, when he resigned to make room for his son, whose election he dictated. Cameron was one of the ablest political organizers the U.S.A. has ever known, and his long undisputed control of Pennsylvania politics was one of the most striking examples of "boss rule" in American history. The definition of an honest politician as "one who when he is bought will stay bought" has been attributed to him. He died on June 26, 1889.

His son JAMES DONALD CAMERON (1833–1918) was born at Middletown, Pa., on May 14, 1833, graduated at Princeton in 1852, and became actively interested in his father's banking and railway enterprises. Trained in the political school of his father, he developed into an astute politician. From June 1876 to March 1877 he was secretary of war in President Grant's cabinet. In the Republican national convention of 1876 he took an influential part in preventing the nomination of James G. Blaine, and later was one of those who directed the policy of the Republicans in the struggle for the presidency between Tilden and Hayes. From 1877 until 1897 he was a member of the U.S. Senate. He died on Aug. 30, 1918.

**CAMERON, VERNEY LOVETT** (1844–1894), British traveller in central Africa, was born at Radipole, near Weymouth,

Dorsetshire, on July 1, 1844. He entered the navy in 1857, served in the Abyssinian campaign of 1868, and was employed for a considerable time in the suppression of the East African slave trade. He was selected to command an expedition sent by the Royal Geographical Society in 1873, to succour Dr. Livingstone and to make independent explorations. Not long after the expedition left Zanzibar, Livingstone's servants were met bearing the dead body of their master. Cameron's two European companions turned back, but he continued his march and reached Ujiji, on Lake Tanganyika, in Feb. 1874, where he found and sent to England Livingstone's papers. Cameron spent some time determining the true form of the south part of the lake, and solved the question of its outlet by the discovery of the Lukuga river. From Tanganyika he struck westward to Nyangwe, the Arab town on the Lualaba previously visited by Livingstone. This river Cameron rightly believed to be the main stream of the Congo, and could not procure canoes to follow it down, owing to his refusal to countenance slavery. He therefore turned south-west. After tracing the Congo-Zambezi watershed for hundreds of miles he reached Bihe and finally arrived at the coast on Nov. 28, 1875, being the first European to cross equatorial Africa from sea to sea. His book *Across Africa* (1877) contains valuable suggestions for the opening up of the continent, including the utilization of the great lakes as a "Cape to Cairo" connection. In recognition of his work he was promoted to the rank of commander, made a C.B., and received the gold medal of the Geographical Society. Cameron visited the Euphrates valley in 1878-1879, and accompanied Sir R. G. Burton in his West African journey of 1882, and was joint author with Burton of *To the Gold Coast for Gold* (1883). He was killed, near Leighton Buzzard (Bedford) by a fall from horseback on March 24, 1894.

A summary of Cameron's great journey, from his own pen, appears in Dr. Robert Brown's *The Story of Africa*, vol. ii. pp. 266-279 (1893).

**CAMERON OF LOCHIEL, SIR EWEN** (1629-1719), Scottish highland chieftain, passed part of his youth with the marquis of Argyll at Inverary, leaving his guardian about 1647 to succeed his grandfather as chief of the clan Cameron. In 1653 Lochiel joined the earl of Glencairn in his rising on behalf of Charles II. In July 1689 he was with Viscount Dundee at Killiecrankie. He was too old to share personally in the Jacobite rising of 1715, but his sympathies were with the Stuarts, and his son led the Camerons at Sheriffmuir. Lochiel, who died in Feb. 1719, is called by Macaulay the "Ulysses of the Highlands." He is said to have killed the last wolf in Scotland. An incident showing his strength and ferocity in single combat is used by Sir Walter Scott in *The Lady of the Lake* (canto v.). Lochiel's son and successor, John, who was attainted for sharing in the rebellion of 1715, died in Flanders in 1748. John's son Donald, sometimes called "gentle Lochiel," was wounded at Culloden, and escaped to France, dying in the same year as his father. The 79th regiment, or Cameron Highlanders, was raised from among the members of the clan in 1793 by Sir Alan Cameron (1753-1828).

See *Memoirs of Sir Ewen Cameron of Lochiel* (Bannatyne Club, 1842).

**CAMERON**, a city in the cotton region of central Texas, U.S.A., on the Santa Fe and the Southern Pacific railways; the county-seat of Milan county. The population was 4,298 in 1920, in 1930, 4,565. It is on the edge of an oil-field, and has an oil refinery, cotton-gins and compresses, cottonseed-oil mills and other manufacturing industries.

**CAMERONIANS**, the name given to that section of the Scottish Covenanters (*q.v.*) who followed Richard Cameron (*q.v.*), and were devoted to the covenanting faith and the maintenance of the Presbyterian form of public worship. Refusing to take the oaths of allegiance to an "uncovenanted" ruler, or to exercise any civil function, they passed through a period of trial and found some difficulty in maintaining a regular ministry; but in 1706 they were reinforced by some converts from the established church, and in 1743 their first presbytery was constituted at Braehead, when they took the official title of Reformed Presbyterians. In 1863 the Cameronians, or Reformed Presbyterians, decided to inflict no penalties upon those members who had taken

the oaths, or had exercised civil functions, and consequently a few congregations seceded. In 1876 the general body of the Reformed Presbyterians united with the Free Church of Scotland, leaving the few seceding congregations as the representatives of the principles of the Cameronians. In the British army the first battalion of the Cameronians (Scottish Rifles) is directly descended from the "Cameronian guard," which, composed of Cameronians, was embodied by the convention parliament in 1689, and was employed to restore order in the Highlands.

See J. H. Burton, *History of Scotland*, vols. vii. and viii. (Edinburgh, 1905); A. Lang, *History of Scotland*, vol. iv. (Edinburgh, 1907); Herkless, art. "Covenanters" in Hastings' *Encyclopædia of Religion and Ethics*, vol. iv.

**CAMEROONS**, a region of West Africa, bounded west by the Atlantic, north-west by Nigeria, north by Lake Chad, south and east by French Equatorial Africa, and for a short distance south-west by Spanish Guinea; area about 190,000sq.m. The coast line begins at the great bend of Africa from east to south forming the Bight of Biafra and has a length of 220m. Its chief indentation is the large bay or estuary named by its Portuguese discoverers Rio das Camarões (river of prawns); hence "the Cameroons" in English usage; French, Cameroun, and German, Kamerun. From 1884 to 1919 it was a German protectorate. By the treaty of Versailles Germany relinquished sovereignty, a mandate to administer the country being given to France and Great Britain.

**Physical Features.**—The greater part of the south and centre of the country is a plateau with a general elevation of 2,000ft., higher towards the west, where it descends in steps to the narrow coast belt, and to the south-east falling in terraces to the Congo basin. North and north-west the plateau is bounded by rugged, broken mountains, which stretch across the country in the form of an arc; north of them is the hilly region of Adamawa, traversed by the valley of the upper Benue (the great tributary of the Niger); and north again, beyond the Benue valley, are on the west the Mandara mountains (4,000ft.) and the alluvial plains (800 to 1,000ft.) which lead to Lake Chad and once formed part of its bed.

BY COURTESY OF THE BOARD OF FOREIGN MISSIONS

A CAMEROON NATIVE CLIMBING A PALM TREE

At the western end of the arc-like mountain ranges, but isolated, rises Mt. Cameroon, an active volcano. Its base covers 700 to 800sq.m. It has two well-defined peaks, Great Cameroon (13,370ft.), in which are a number of craters, and Little Cameroon (5,820 ft.), from bottom to top covered with dense forest. Alone of the great mountains of Africa Cameroon lies by the sea; its south-western base is washed by the Atlantic. From any point of vantage, but especially from the sea, it presents a magnificent spectacle, while some 30m. westward Clarence peak, the highest point of Fernando Po island, rises from the ocean. Mt. Cameroon was in eruption in 1909 and again in 1922; its western side is one of the rainiest regions in the world, with 400 to 430in. in the year. The Cameroons estuary, bay or river—all three terms are used—lies immediately south of the mountain. The estuary is 20m. wide; into it flow several rivers, the chief being the Mungo and Wuri. The largest of the rivers, the Sanaga (known in its upper course as the Lom) and the Nyong, which, rising in the central plateau, flow direct to the Atlantic, entering the ocean south of the estuary. These and other streams have their headwaters in the Jade massif, in the north-east of the plateau, where also rise the Logone and other rivers that flow north to the Shari (Lake Chad basin), as well as rivers which flow south-east to the Sanga, an affluent of the Congo. Thus the Cameroons has four

distinct river systems. It is noteworthy that there is a connection between the Niger and Chad systems. From a marshy lake in Adamawa called Tuburi there issues at its western end a tributary of the Benue and from its eastern end a tributary of the Logone.

**Climate.**—The Cameroons has a typically tropical climate and is unsuited for settlement by Europeans. Temperature everywhere is high, not being below 70° over the greater part of the country in the cool months, while it rises in the hot season to over 90° in the Lake Chad basin. The daily variation is fairly marked, especially in the central plateau, in some parts of which it is as low as 66° in the warmest month (April) and no higher than 62° in the coolest (Aug.). With the sun in the south there is in the early part of the year a dry, cool, dust-laden wind from the Sahara; by July, when the sun is over the Sahara, the wind blows from the south, mainly south-westerly, rain-laden sea-winds. Rain falls usually in every month of the year (except in the far north), chiefly in the second half; it is heaviest on the coast—155in. yearly at Duala; is less on the plateau (Yaunde, 62in.), and in parts of the Chad basin sinks to 18 to 13in. In the south there are two wet and two dry seasons in the year. The special conditions on Mt. Cameroon have already been noted. Large areas of the country are malaria ridden, but malaria ceases above a height of 4,000ft.

**Flora and Fauna.**—Very large areas both of plateau and mountain are covered by primeval forest with trees 200 and 250ft. high, their trunks covered with parasitic growths, such as orchids and arums. In the north there are wide stretches of open savannahs; all the creeks and swamps are lined with mangroves and behind is dense jungle. The swamps are often rendered beautiful by the enormous red-purple *Lissochilus* orchid, which rises 10 to 15ft. above the water. Part of the coast belt is grass-covered. The forest trees include mahogany, ebony, teak and other valuable timber, the *Funtumia elastic* (rubber tree) and the *Landolphia* (rubber vine), the kola tree, the bamboo palm and oil palm, the last named being very abundant. The coffee shrub and cotton plant (in the far north) are found wild, and there are fibre yielding plants such as *ceiba pentandra*. In the north there are gum-producing acacias. Tree-ferns of great beauty are characteristic of the middle belt (4,000 to 7,000ft.) of Mt. Cameroon. Bananas are cultivated, and rice, maize, plantains, yams and cassava are native food crops.

Among the animals the gorilla and chimpanzee are notable. The carnivora include the lion and leopard, and large rodents like the porcupine and cane rat are very common. There are several species of venomous snakes. Large herds of antelope are found in the plains and the elephant, though now little seen in the Cameroons estuary region, still inhabits many districts. Buffalo live in the forests; ostriches are found in the Lake Chad region; and cattle and horses are reared in the north and centre. South of the Sanaga river the tsetse fly is common; and mosquitoes are abundant in all the river valleys, among the species being *glossina*, the carrier of sleeping-sickness. Bees are found in most regions and the collection of honey is a regular industry.

**Inhabitants.**—The natives of the Cameroons are Bantu speaking negroes in the south and centre; Sudan negroes (*i.e.*, tribes speaking dissimilar languages) on the north. There are also in the north and centre numbers of immigrant Hausa (*q.v.*) and the ruling class in Dikwa and Adamawa are Fula (*q.v.*). There are also in the Lake Chad region the Arabic speaking Shua. In general in the north Mohammedanism prevails, with corresponding social organization, though some tribes maintain a sturdy paganism.

The Bantu speaking peoples—the bulk of the population—have been divided into the Bakoko and Bakundu groups, and, in the south-east, the Fang (*q.v.*) group. For long only the coast tribes were known, of these the Duala (*q.v.*) and Wuri occupying part of the Cameroons estuary were the most important. Cannibalism persisted among the Ngi (in the Bamedia district) as lately as 1922. Belief in witchcraft too remained among tribes, such as the Bakwiri (*q.v.*), long under the influence of Christian missions. Both the Duala and Bakwiri were noted for the use of "drum-language." Polygamy is almost universal; few men have more

than three wives, but at Bali, Cameroons province, in 1925 one man had 99 wives—the next most-married man having but 25—while there were 460 bachelors.

In the forests are a number of pygmy people, who live by hunting and are in semi-dependence on their Bantu neighbours. Generally known as Babingas they have characteristics, apart from their small size, which distinguish them from the negro proper. A French estimate (1924) put the pygmies as numbering 20,000.

**Trade Under German Rule.**—The Cameroons estuary afforded safe and ample accommodation for ships, and European merchants were attracted thither, the chief centre of trade being the adjoining Bell and Akwa towns on the Wuri river. When German authority was established in 1884 British, French and German firms all had agents in the river. The Germans renamed Bell and Akwa towns Duala and developed it greatly, while headquarters for the administration were made at Buea, on the southern slopes of Mt. Cameroon. Next to Duala the port of most value was Kribi, in the south, whence much forest produce

BY COURTESY OF THE BOARD OF FOREIGN MISSIONS

CAMEROON NATIVE PLAITING A GRASS HAT

was shipped. Trade was much hampered by defective means of transport, as well as by conflicts with the natives. Of all the German possessions in Africa the Cameroons remained to the end of their rule the least developed. Two railways were begun, one from Bonaberi on the north shores of the estuary and designed to be taken eventually to Adamawa, the other from Duala eastward. Apart from these enterprises German energy was expended chiefly on the development of plantations on the slopes of Mt. Cameroon, with Victoria on Ambas Bay (at the foot of the mountain) as port. These plantations proved successful and 54,000ac. were under cultivation in 1912. Of this total 26,000ac. were devoted to cocoa and 17,000 to rubber. Rubber, palm kernels and palm oil, cocoa and ivory were the chief exports, which in 1913, the last full year of German control, were valued at about £1,200,000. Rubber shipments were about half the total value of the exports. In every year of German rule from 1902 onward imports exceeded in value the exports.

**British Cameroons.**—The area under British mandate covers 33,750sq.m., with a pop. (1925) of 183 Europeans and 687,000 natives. It includes in the far north the Dikwa emirate (pop. 177,000), the part of Bornu which was in German occupation, and has been re-attached to the ancient state of Bornu, now the Bornu province of Nigeria. In the centre the Adamawa districts are administered as part of the Yola province of Nigeria. These with other small adjacent regions had in 1925 some 120,000 inhabitants. Of most importance is the southern area, which includes Mt. Cameroon, with all the ex-German plantations, Buea, and the port of Victoria. This area is named Cameroons province and is in charge of a senior resident. In 1925 the inhabitants numbered 390,000. By the British the system of indirect rule adopted in Nigeria was applied to the Cameroons. In the north—Dikwa and Adamawa, where well-recognized native states already existed—this system presented comparatively few difficulties. In the Cameroons province there were a few organized native states, such as that of the Bansa; but in many districts there was less to build upon.

European interests are centred in the plantations on the slopes of Mt. Cameroon. In the Victoria and Kumba divisions 403sq.m. out of a total of 5,222sq.m.—probably an excessive proportion—have been alienated for European private enterprise; in 1927 only 48,000ac. were, however, under cultivation. From 1915 to 1924 the plantations were in the care of a government department. They were sold by auction in London in Nov. 1924, realizing £224,670; the purchasers, who for the most part were Germans, entering into possession in March 1925. Cocoa is the chief crop, and its cultivation has been taken up by natives; there are also coffee,

banana and rubber estates. The bulk of the trade passes through the port of Victoria, from which a railway to Buea (the administrative capital) serves the plantations. Elsewhere traffic is by motor on metalled roads, which include one road, 200m. long as designed, to connect with the Nigerian trunk road system in the Cross River district. The export trade depends a good deal on the cocoa crop; 1923 was a bad year and the value of exports fell from £140,000 in 1922 to £74,000, but by 1926 exports had risen to £220,000. Besides cocoa the chief exports are kola nuts, palm kernels and palm oil. The imports, largely textiles, provisions, tobacco, motor spirit and machinery, were valued at £52,000 in 1922 and at £275,000 in 1926. Shipping is mainly in German and British hands. In the war years (1914-18) and those following revenue fell short of receipts, of which the chief items are customs and direct taxation. From 1916 to the end of 1925 the total deficit was £291,000. Deficits are made good by the Nigerian Treasury, and the Cameroons accounts are included in the Nigerian budget.

**French Cameroons.**—The area under French mandate is about 160,000sq.m. with a population estimated in 1924 at 2,700,000, including some 2,000 Europeans, half of whom lived in Duala (native pop. 30,000), the largest town, chief seaport and capital until 1921, when the seat of administration was removed to Yaunde, a fairly healthy station on the central plateau. French Cameroons is governed as a separate entity, with administrative and fiscal autonomy, by a commissioner, aided by a council, responsible to Paris. The resources of the country are agricultural, pastoral and sylvan; there are neither minerals nor manufactures. While there are European owned plantations—in which bananas, Cape tobacco, cocoa and oil palms are cultivated—production is mainly by natives. External trade is mainly in palm kernels and palm oil, timber and (since 1924) cocoa; the imports are mostly cotton goods (from England), clothing, salt and machinery. Trade developed, exports rising steadily from 31,000,000fr. in 1919 to 113,000,000fr. in 1925; in the same period imports rose from 17,000,000 to 126,000,000 francs. This increase was due in part to better transport conditions. The central railway, built by the Germans from Duala to Esaka (112m.), was in March 1927 completed to Yaunde (another 90m.), while, radiating chiefly from Yaunde, some 1,200m. of main roads were built. The northern railway from Bonaberi, 93m., built by the Germans, was improved, and from railhead a main road was continued north to the large native town of Fumbum. This northern line runs near the frontier of British Cameroons province and taps its trade. The general progress of French Cameroons was shown by the favourable financial situation; the budget showed successive surpluses, so that in 1925 there were 4,600,000fr. in the Caisse de Reserve. The budget for 1926 was balanced at 61,854,000 francs. An unusual fiscal feature is a poll tax on married women without children.

### HISTORY

The Cameroon estuary and the neighbouring coast were discovered towards the end of the 15th century by the Portuguese navigator Fernando Po. Not until the 17th century were European trading stations, called factories, established. The Duala and other coast tribes, who would not allow strangers to go inland, took goods on trust from the white merchants and bartered them with the forest tribes for ivory, rubber, and other produce—including slaves. This trust system worked well and continued until the German occupation of the country, when inland traders were allowed to come to the coast. Meanwhile the Duala, keen business men, had prospered and the "kings" of Akwa and Bell, the chief trading stations, were wealthy merchant princes. By the end of the 18th century the coast region had come politically under British influence and in 1837 the King of Bimbia made over a large part of the country round the estuary to Great Britain. No advantage appears to have been taken of this cession, but in 1845 British missionaries made a settlement in the estuary, at a time when there was still a flourishing trade in slaves between the Cameroons and America. In the year named, Alfred Saker (1814-80), of the Baptist Missionary Society, obtained from the Akwa family the site of a mission sta-

tion. Saker, whose headquarters were then on the island of Fernando Po, established another mission station at Bimbia in 1848. When in 1858 the Baptists were expelled from Fernando Po a colony of freed negroes who then left the island was founded in Amba bay, Saker naming the settlement Victoria. It was two years later that Messrs. Woermann, of Hamburg, established the first German "factory" in the estuary. Saker reduced the Duala language to writing and before he left the Cameroons, in 1876 witnessed, a year or two previously, the final suppression of the over-sea slave trade.

Although the British consul for the Oil Rivers during this period exercised a good deal of authority over the native chiefs, requests made by them—in particular by the Duala chiefs in 1882—for annexation by Great Britain were refused or neglected, with the result that when Germany started on her quest to pick up unappropriated parts of the African coast she was enabled to secure the Cameroons. A treaty with King Bell was negotiated by Dr. Gustav Nachtigal, the signature of the king and the other chiefs being obtained at midnight on July 15, 1884. Five days later E. H. Hewett, British consul, arrived with a mission to annex the country to Great Britain.<sup>1</sup> Though too late to secure King Bell's territory Mr. Hewett concluded treaties with all the neighbouring chiefs, but the British Government decided to recognize the German claim not only to Bell town, but to the whole Cameroons region, which the Germans named Kamerun. Subsequent agreements with Great Britain and France gave the newly acquired territory an extension inland to Lake Chad, including parts of the Fulani states of Adamawa and Bornu. The Baptist settlement at Victoria, at first excluded from the German protectorate, passed to Germany in March 1887.

The extension of German authority inland was gradual and was not effected without severe opposition and a number of revolts. The shores of Lake Chad were first reached by a German military force on May 2, 1902. In the northern regions, with their strong Muslim and non-negro elements, the Germans allowed the native chiefs to retain a good deal of authority. Most attention was paid to the development of the coast district around Mt. Cameroon, where many plantations were worked, and to the exploitation of the riches of the forests. Following risings in various districts in 1904 and 1905, the then governor, Herr von Puttkamer, was recalled in 1906. Administrative methods afterwards improved, to the benefit of the natives and of the plantations.

By the river Sanga the Cameroons had a connection with the Congo, and efforts were made at development in that direction. When, in the negotiations with France in 1911, Germany agreed to withdraw opposition to the establishment of a French protectorate over Morocco she obtained compensation by the addition to the Cameroons of some 107,000sq.m. of French Equatorial Africa (*q.v.*). This brought German territory at one point down to the Congo river itself. But in 1914-16 the Cameroons were conquered by French and British forces and in 1919, by the Treaty of Versailles, Germany renounced her sovereignty over it. The regions annexed in 1911 were restored to French Equatorial Africa; a mandate to administer the original colony was given by the Supreme Council to France and Great Britain. The portions adjoining Nigeria were given to Great Britain. They included Mt. Cameroon and "German" Bornu and these regions were administered as integral parts of Nigeria. Some five-sixths of the Cameroons came under French mandate and this part was administered as a separate entity. The terms of the mandate were approved by the Council of the League of Nations on July 20, 1922. The negotiations ended with the grant to citizens of the United States of equal economic rights with nationals of members of the League.

**BIBLIOGRAPHY.**—E. B. Underhill's *Alfred Saker . . . a Biography* (1884) deals with early missionary efforts; Mary Kingsley's *Travels in West Africa* (1897) includes the Cameroons; *Cameroon*, a useful handbook issued by H. M. Stationery Office, London, 1920, with bibliography; annual reports on the French and British spheres are presented to the League of Nations and officially published. See also F. W. H. Migeod, *Through British Cameroons* (1925), a travel diary by a competent observer. (F. R. C.)

<sup>1</sup>On July 26 a French gunboat also entered the estuary on a belated annexation mission.

**CAMEROONS, OPERATIONS IN.** The German forces in the Protectorate at the outbreak of the World War were commanded by Colonel Zimmerman, an able and resolute soldier, and consisted of approximately 200 Europeans and 1,550 natives in the military force and 40 Europeans and 1,255 natives in the police force. Some hundreds of settlers were available, as were a number of sailors from ships which made for the Cameroons estuary when war was declared. Considerable numbers of natives were trained as *askaris* during the campaign, and to some extent local levies co-operated, though the natives generally were hostile to their German masters. These forces were scattered, the main portion of them being about Duala, the chief port.

The offensive was initiated by the Allies. Bonga and Singa, the most advanced enemy posts in the two salients, were captured by the French on Aug. 6 and 7, 1914, a German offensive being thus forestalled. Two French columns were then despatched: the one (Hutin) north along the Sanga, with Lomie as its objective, the other (Morrison) moving west on Dume from Singa along the Lobaye. These enemy posts were in the centre of the Cameroons. On Sept. 21 General Largeau in the north occupied Kuseri in the Lake Chad region.

**British Movements.**—Meanwhile British forces had moved from Nigeria, and a column under Captain Fox crossed the frontier on Aug. 25, and unsuccessfully attacked Mora, a hill post in the north. A French column (Brisset), sent to co-operate with Fox, occupied Marua south of Mora on Dec. 12, with the result that the Lake Chad region was cleared of the enemy, except the garrison of Mora, which gallantly held out through all the campaign, surrendering upon terms at its conclusion.

Two other British columns invaded the Cameroons on Aug. 25 only to meet with repulse.

**Anglo-French Offensive.**—About the middle of September an Anglo-French expeditionary force, 4,300 strong, formed in equal proportions from British and French negro troops, and under the British commander-in-chief, General Dobell, embarked at different ports, and, forcing the barrier at Duala, bombarded that port on Sept. 26. On the surrender of the port on the following day 400 Germans and 30,915 tons of shipping were captured. Colonel Zimmerman withdrew to Edea, 40m. to the south-east. Three columns were at once directed in pursuit of the enemy at Edea which, after continuous opposition, was occupied on Oct. 26. A French garrison under Colonel Mayer was installed at Edea, the German commander-in-chief having retired to Yaunde, 100m. east, on a plateau beyond the forest belt.

Mayer, owing to the weakness of his force, being condemned to passive defence, the British forces proceeded to clear the country between the Cameroons estuary and Nigeria. By the end of 1914 the whole of the northern railway and Buea, the enemy administrative capital, had been occupied. On Jan. 5, 1915, Mayer beat off an attack on Edea with heavy loss to the attackers. Elsewhere the Allied offensive had almost ceased, Hutin's column alone had made some progress, and he had been joined by a small Belgian contingent. Reorganization was effected and Brig.-Gen. Cunliffe was appointed to command the Allied troops in the north, where the enemy was taking the offensive. Reinforcements reached Gen. Dobell at Duala in February.

A concentric advance upon Yaunde was decided upon, but was begun prematurely, largely in consequence of the usual difficulties which beset allies who endeavour to co-operate for the first time. The force was strongly opposed in the dense bush and when Yaunde was still 40m. distant, dysentery became rife, leading to a withdrawal to the Edea district. On the same date, however, June 28, Cunliffe occupied Ngaundere, some 300m. north-east of Yaunde. Here, simultaneously with the withdrawal to Edea, a halt was called. Hutin occupied Lomie—150m. south-south-east of Yaunde—on June 25 and Morrison took Dume a month later.

The general Allied offensive was resumed, and by early October General Dobell was moving in from the west, Cunliffe from the north and Hutin and Morrison from the east. The maximum Allied strength, about 15,000, was now disposed against the enemy, whose forces were estimated at 10,000 (inclusive of 700 Europeans). The opposition was, as before, vigorous and protracted.

The British force emerged first from the forest belt and on Dec. 17 were at Mangas in open country and about 50m. west of Yaunde. On Dec. 21 the French column, which had had severe fighting and many casualties, reached Mangle's 20m. south-east of Mangas. The British troops were instructed not to await the French arrival at Mangle's, and accordingly pushed straight on for Yaunde, which Colonel Gorges entered unopposed on Jan. 1, 1916.

**Conclusion of the Campaign.**—From Dec. 22 opposition by the enemy had ceased. Colonel Zimmerman, as soon as he knew that the Allied columns were clear of the forest, decided to give up the contest. He evacuated Yaunde and, together with the governor and 823 Germans, including civilians and his troops and carriers, headed south-west for Spanish Guinea, of which the nearest point was 125m. distant. He was pursued, but although forced to fight a rear-guard action on Jan. 8, he eluded the columns which had been sent to the borders of Spanish Guinea and were waiting to bar his entry into neutral territory. The first part of his forces, quickly followed by the rest, entered Spanish territory on Feb. 4 and with the surrender of the gallant garrison at Mora on Feb. 18, the conquest of the Cameroons was complete.

See E. Dane, *British Campaigns in Africa* (1919); H. C. O'Neill, *The War in Africa* (1919); Maj.-Gen. Sir C. Dobell, *The Campaign in the Cameroons, 1914-16* (1922).

**CAMILING**, a municipality (with administration centre and 18 *barrios* or districts), in the north-west part of the province of Tarlac, Luzon, Philippine Islands, on the Camiling river, about 80 m. N.N.W. of Manila. Pop (1918) 23,375, of whom none were white. Its chief products are rice, corn and sugar; fine timbers grow in the vicinity. In 1918 it had 3 manufacturing establishments and 87 household industry establishments, with small outputs from both. Of the 17 schools, 14 were public. The language spoken is Pampanga.

**CAMILLUS, MARCUS FURIUS**, Roman soldier and statesman, of patrician descent, censor in 403 B.C. He triumphed four times, was five times dictator, and was honoured with the title of Second Founder of Rome. Mommsen sums up his place in history by describing him as one who "first opened up to his fellow-countrymen the brilliant and perilous career of foreign conquest." When accused of having unfairly distributed the spoil taken at Veii, which was captured by him after a ten years' siege, he went into voluntary exile at Ardea. Subsequently the Romans, when besieged by the Gauls, created him dictator; he completely defeated the enemy (but see BRENNUS and ROME: *History*). He afterwards fought successfully against the Aequi, Volsci, and Etruscans and repelled a fresh invasion of the Gauls in 367. Though patrician in sympathy, he saw the necessity of making concessions to the plebeians and was instrumental in passing the Licinian laws, 367 B.C. (see PATRICIANS). He died of the plague in 365. The story of Camillus is no doubt largely traditional.

See Livy, v. 10, vi. 4; Plutarch, *Camillus*. For the Gallic retreat, see Polybius ii. 18; T. Mommsen *History of Rome* (trans. Dickson, 1901) ii. chap. iv.

**CAMISARDS**, the name given to the Protestant peasantry of the Cévennes who, from 1702 to 1705, and for some years afterwards, carried on an organized military resistance to the revocation of the Edict of Nantes. The Camisards (from *camisade*, obs. Fr. for "a night attack," from the Ital. *camiciata*, formed from *camicia*, a shirt, from the shirt being worn over the armour to distinguish friends from foes), were also called Barbets ("water-dogs," a term also applied to the Waldenses), Vagabonds, Assemblers, Fanatics and the Children of God. They belonged to that romance-speaking people who made the South of France the most fertile nursing ground of mediaeval heresy (see CATHARS and ALBIGENSES). At the time of the Reformation the same causes produced like results.

In 1686 Pierre Jurieu published his work *L'Accomplissement des prophéties*, in which, speaking of the Apocalypse, he predicted the end of the persecution of the Huguenots and the fall of Babylon (that is to say of Roman Catholicism) for 1689. The revolution in England seemed to provide a striking corroboration of

his prophecies, and the apocalyptic enthusiasm took so strong a hold on people's minds that Bossuet felt compelled to refute Jurieu's arguments in his *Apocalypse expliquée*, published in 1689. The *Lettres pastorales* of Jurieu (Rotterdam, 1686-87), a series of brief tracts which were secretly circulated in France, continued to narrate events and prodigies in which the author saw the intervention of God, and thus strengthened the courage of his adherents. This religious enthusiasm, under the influence of Du Serre, was manifested for the first time in the Dauphiné. Du Serre, who was a pupil of Jurieu, communicated his mystic faith to young children who were called the "petits prophètes," and went from village to village quoting the most obscure and terrible predictions. (See ANTICHRIST.)

The assassination of the Abbé du Chayla on July 23, 1702, at Ponte de Monvert, marks the beginning of the war of the Cévennes. The abbé, a veteran Catholic missionary from Siam, had been appointed inspector of missions in the Cévennes, where he introduced the "squeezers" (which resembled the Scottish "boot"). His murder was planned by Esprit Séguier, who at once began to carry out his idea of a general massacre of the Catholic priests. He soon fell, and was succeeded by Laporte, an old soldier, who, as his troop increased, assumed the title of "the colonel of the children of God," and named his camp the "camp of the Eternal." He used to lead his followers to the fight singing Clement Marot's grand version of the 68th Psalm, "Que Dieu se montre seulement," to the music of Goudimel. The movement was essentially a popular one; there were no noblemen among its leaders. Besides Laporte, the forest-ranger Castanet, the wool-carders Conderc and Mazel, the soldiers Catinat, Joany and Ravenel were selected as captains—all men whom the *théomanie* or prophetic malady had visited. The most important figures are those of Roland, who afterwards issued the following despatch to the inhabitants of St. André, "Nous, Comte et Seigneur Roland, généralissime des Protestants de France, nous ordonnons que vous ayez à congédier dans trois jours tous les prêtres et missionnaires qui sont chez vous, sous peine d'être brûlés tout vifs, vous et eux" (Court, i. p. 210); and Jean Cavalier, the baker's boy, who, at the age of 17, commanded the southern army of the Camisards, and who, after defeating successively the Comte de Broglie, Montrevel, Berwick and Villars, made an honourable peace. (See CAVALIER, JEAN.)

Cavalier for nearly two years continued to direct the war. Regular taxes were raised, arsenals were formed in the great limestone caves of the district, the Catholic churches and their decorations were burned and the clergy driven away. Occasionally routed in regular engagements, the Camisards, through their desperate valour and the rapidity of their movements, were constantly successful in skirmishes, night attacks and ambushes. The rising was far from being general, and never extended to more than three or four thousand men, but it was rendered dangerous by the secret, and sometimes the open, support of the people in general. Their knowledge of a mountainous country clothed in forests and without roads, gave the insurgents an enormous advantage over the royal troops, and the rebellion was not finally suppressed until Baille had constructed roads throughout the country.

Montrevel adopted a policy of extermination, and 466 villages were burned in the Upper Cévennes alone, the population being for the most part put to the sword. Pope Clement XI. assisted in this work by issuing a bull against the "execrable race of the ancient Albigenes," and promising remission of sins to the holy militia which was now formed among the Catholic population, and called the Florentines, Cadets of the Cross, or White Camisards. Villars, the victor of Höchstädt and Friedlingen, saw that conciliation was necessary; he took advantage of the feelings of horror with which the quiet Protestants of Nîmes and other towns now regarded the war, and published an amnesty. In May 1704 a formal meeting between Cavalier and Villars took place at Nîmes, resulting in the despatch to the court of a document containing the requests of the Camisards. The three leading requests for liberty of conscience and the right of assembly outside walled towns, for the liberation of those sentenced to prison or the galleys under the revocation, and for the restitution to the emigrants

of their property and civil rights, were all granted—the first on condition of no churches being built, and the third on condition of an oath of allegiance being taken. The greater part of the Camisard army under Roland, Ravenel, and Joany would not accept the terms which Cavalier had arranged, and, insisting that the Edict of Nantes must be restored, continued the war till Jan. 1705, by which time all their leaders were either killed or dispersed. In 1709 Mazel and Claris, with the aid of two preaching women, Marie Desubas and Elizabeth Catalan, made a serious effort to rekindle revolt in the Vivarais; but in 1711 all opposition and all signs of the reformed religion had disappeared. On March 8, 1715, by medals and a proclamation, Louis XIV. announced the entire extinction of heresy.

What we know of the spiritual manifestations in the Cévennes (which much resembled those of the Swedish Raestars of Smaland in 1844) is chiefly derived from *Le Théâtre sacré des Cévennes* (London, 1707), reprinted at Paris in 1847; *A Cry From the Desert*, etc., by John Lacy (1707); *La Clef des prophéties de M. Marion* (London, 1707); *Avertissements prophétiques d'Élie Marion*, etc. (London, 1707). The inspiration (of which there were four degrees, *avertissement*, *souffle*, *prophétie*, *dons*) was sometimes communicated by a kiss at the assembly. The patient, who had gone through several fasts three days in length, became pale and fell insensible to the ground. Violent agitations of the limbs and head followed, as Voltaire remarks, "quite according to the ancient custom of all nations, and the rules of madness transmitted from age to age." Finally the patient (who might be a little child, a woman, a half-witted person) began to speak in the good French of the Huguenot Bible words such as these: "Mes frères, amendez-vous, faites pénitence, la fin du monde approche; le jugement général sera dans trois mois; repentez-vous du grand péché que vous avez commis d'aller à la messe; c'est le Saint-Esprit qui parle par ma bouche," Brueys, *Histoire du fanatisme de notre temps* (Utrecht, 1737, vol. i. p. 153). The discourse might go on for two hours; after which the patient could only express himself in his native patois, and had no recollection of his "ecstasy." All kinds of miracles attended on the Camisards. Lights in the sky guided them to places of safety, voices sang encouragement to them, shots and wounds were often harmless. Those entranced fell from trees without hurting themselves; they shed tears of blood; and they subsisted without food or sleep for nine days. The supernatural was part of their life. The publication of J. F. K. Hecker's work, *Die Volkskrankheiten des Mittelalters*, made it possible to consider the subject in its true relation. This was translated into English in 1844 by B. G. Babington as *The Epidemics of the Middle Ages*.

**CAMMAERTS, ÉMILE** (1878— ), Belgian poet, was born at Brussels on March 16, 1878. In 1908 he settled in England. His earlier works include four volumes of translations of

Ruskin into French, and *Les Bellini* (later ed. 1927), an essay in criticism; he has also written two plays, *Les Deux Bossus* (1917), and *La Veillée de Noël* (1917). He attained his widest popularity by poems written during the World War, including *Chants patriotiques et autres poèmes* (1915, trans. as *Belgian Poems*, 1915); *Les Trois Rois et autres poèmes* (1916, trans. as *New Belgian Poems*, 1916); and *Messines et autres poèmes* (Eng. trans. 1918). He also wrote *A Ma Patrie enchainée* (1918, trans. as *Through the Iron Bars*, 1918), an account of the sufferings of Belgium during the World War, and in 1922 a further collection of poems *Poèmes intimes* (Brussels, 1922). He married the daughter of the singer Marie Brema, Tita Brand, who was responsible for the translations of his poems mentioned above.

**CAMOENS (CAMÕES), LUIS DE** (1524-1580), Portugal's renowned epic poet and one of the greatest lyric poets of 16th century Europe, was born either at Coimbra or Lisbon about or in the year 1524. He came of Galician stock, owners of land near Finisterre; his ancestor, the soldier-poet Vasco Perez de Camões, fled to Portugal after the rout of Montiel in 1369, and in 1385 fought at Aljubarrota on the losing side of Castille. His grandson married Dona Guiomar Vaz da Gama, of an Algarvian family soon to be immortalized by the discovery of the sea-route to India. Their son Simão Vaz de Camões was born at Coimbra a few years before that world-shaking event; he married a lady of a Santarem family, Dona Anna de Sá e Macedo, and their son Luis Vaz de Camões, perhaps an only child, was born probably in the year of his great kinsman Vasco da Gama's death. The death of Simão Vaz at Goa, whither he had gone as captain of a ship in the hope of redressing the fortunes of a poor "cavaleiro fidalgo," left his widow and child in something like penury, and it is perhaps unlikely under these circumstances that the boy would have been sent from Lisbon to study at the famous university which had been transferred to Coimbra in 1537. This seems to incline the scales slightly in favour of Coimbra in the very evenly balanced claims of Coimbra and Lisbon to be the poet's birthplace. We only know that he studied at Coimbra university, then described as a second Athens, to which King João III. by lavish salaries enticed professors from many foreign countries; they included men of world-wide reputation from Salamanca, Paris and Bordeaux, among them George Buchanan. How thorough was the education of the young Camões is evidenced by the general scientific and literary culture shown in his work, and his constant classical allusions, a knowledge which he could not have acquired at any other time of his unquiet life and retained to the end. His acquaintance with Latin literature was extensive, and it is very probable, although not certain, that he also knew Greek. These were the years when the Renaissance was making its late appearance in Portugal; the old national school of poetry represented by Gil Vicente was dying out, while Sá de Miranda was fighting an uphill battle in favour of the "dolce stil nuovo." Camões was to excel in either school. A document recently unearthed shows that the poet's cousin, Bento Vaz, was not the powerful prior of the College of Santa Cruz but a poor canon; but, whatever assistance Camões may have received in his studies, there can be no doubt as to his brilliance. His early play, "Os Amphitriões," perhaps acted at Coimbra, and the beautiful canzone "Vam as serenias aguas," written there, testify to the depth and variety of his genius. The fervent humanism of the beautiful old city on the hill above the transparent waters of Mondego and the exquisite surrounding scenery had sunk deep into his spirit, and we may surmise that it was love rather than ambition that drove the poet from the university, where his learning and talent could not fail to be appreciated.

He had fallen in love with a lady described in his early poetry as having a snow-white face and hair of gold. If she belonged to the court and was first seen by the poet on one of the court's periodical visits to Coimbra, it was but natural that he should follow her to Lisbon. The year of his arrival in what had now become one of the most important as well as most interesting capitals in Europe, is uncertain, but it may have been 1545. For the next eight years of the poet's life we are confronted by a series of fluctuating and contradictory conjectures. It is best to abandon

the widely held theory that he came to Lisbon in 1542 as tutor to the son of the second count of Linhares, the infant Dom Antonio de Noronha, who was killed in North Africa at the age of 17 in April 1553. The other tradition, that he fell in love with a lady of the court, Dona Caterina (Natercia) de Ataíde, whom he is alleged to have seen for the first time in a Lisbon church on Good Friday of 1544, is older but scarcely less fragile. Camões sang of a dozen different loves; sometimes they may be the same under different names, sometimes the circumstances are different and make identity impossible. Apart from the charming verses to Barbara, the Indian slave-girl, his most inspired love poems seem to centre round two objects, the early "head of gold and snow," who may conveniently but perhaps incorrectly be called Caterina-Natercia, and secondly a lady who was drowned at sea and is sung under the name of Dinamene. To the latter, now generally assumed to be a Chinese slave-girl with whom he was returning from Macao on the occasion of his shipwreck, were addressed some of his loveliest sonnets, including the famous "Alma minha gentil." As to Natercia, she may have been the daughter of Dom Antonio de Lima, that Dona Caterina de Ataíde who died at an early age in 1556; but there were two other Caterinas of the same surname, neither of whom can be summarily dismissed, while a more recent learned conjecture rejects all three and considers the object of the poet's love to have been King Manuel's daughter, the Infanta Maria, born in 1521. A further very real difficulty consists in attributing the evidently sincere and impassioned early love poems to two different passions, that for the Coimbra lady celebrated in "Vam as serenias aguas" and that for the Lisbon lady first seen in 1544. The attribution of this precocious fickleness seems an error in psychology on the part of the critics, and it is preferable to assume that the object of the poet's love between the years 1542 and 1553 was one and the same.

The years before the departure to India were spent at Lisbon, with the exception of two years' military service in North Africa. The poet and penniless fidalgo, after coming to the capital, continued to woo Natercia at court, where he wrote and produced his second play, "El Rei Seleuco." Either because the subject of this play was held to contain an allusion to the king or because the suit of the poor and indiscreet gentleman and scholar was less favourably received by Natercia's parents than by Natercia, all his hopes were suddenly dashed to earth, and he found himself wandering disconsolately in the Ribatejo country near Santarem, banished from the capital and court. Two years' service in Africa followed (1547-49), during which, either by an accident or under fire of the enemy, Camões lost the sight of his right eye. On returning to Lisbon he found his cousin, Simão Vaz de Camões, high in favour with the youthful Prince João (1537-53), to whom many men of letters looked as their patron, and he probably now made the acquaintance of another of the prince's friends, D. Antonio de Noronha. The poet's hopes again rose high, he had many friends at court, and, although still penniless, enjoyed himself with rowdy boon-companions while waiting to receive some reward for his services in Africa and to win recognition for his literary genius. He continued to write lyrics, probably now composed his play "Filodemo," later acted in India, and began to entertain thoughts of an elaborate epic of the recent glories of his country. The dreamy Coimbra boy had become a rash and generous youth of the world; ladies of the court might gibe at the "one-eyed devil," but were glad to receive his compliments in verse; his comrades dubbed him Trincafortes, the Swashbuckler; and beneath these superficial frivolities his love for Natercia continued. As suddenly and completely as in 1547 his hopes and prospects ended. During the Corpus procession on June 16, 1552, Camões wounded a certain Gonçalo Borges, a court official, in a street quarrel, and lay for eight months in the Lisbon gaol.

Within three weeks of his release on March 7, he set sail for India (March 26, 1553). He went as a common soldier bound for three years' service, and soon after his arrival at Goa took part in a punitive expedition against the King of Chembe on the coast of Malabar in November. Immediately after his return to Goa he served in an expedition to the Red sea. From Cape Guardafui the Portuguese fleet sailed to Ormuz on the Persian gulf, and after a

successful engagement off Maskat, in which six Turkish ships were captured, returned to Goa in November 1554. Camões must certainly have received some of the spoils, and for some months was able to live quietly and happily at Goa, engaged in the composition of some of his noblest lyrics and of the first six books of the *Lusiads*. The new Viceroy, Pedro de Mascarenhas, had been chamberlain to Prince João at Lisbon, and is likely to have been an old friend of the poet, but he died in 1555 within a year of his appointment to India. Under his successor, the Governor Francisco de Barreto, Camões received an appointment at Macao as trustee for the property of dead or absent Portuguese. Posts of all kinds were eagerly coveted in India, the obscurest appointment disappointed a score of claimants, and there is no reason to consider Camões' appointment as a punishment, however little it may have corresponded to his hopes in 1555, and many as may have been the envious enemies which his favour with the viceroy and his own sharp satirical tongue brought him in that motley crowded Goa of gossip and intrigue. On his way to Macao, he may have gone to the Moluccas, but this is by no means certain. We know a little more about his return voyage. It would appear that his return was due to a quarrel with the captain of the "silver and silk ship" trading between Japan and Goa. Captain Leonel de Sousa, incensed at being deprived of jurisdiction as *provedor* at Macao (the post given to Camões) is alleged to have arrested him and brought him back to Goa in chains. Much has been made of two words of the *Lusiads* referring to an "unjust order" (*injusto mando*), which it is perhaps preferable to take in a more general sense as alluding to the original exile to India in 1553. The poet's term of office at Macao was probably nearly up when Captain Sousa put in there at the end of 1558. The desire to give a dramatic cast to every step in the poet's career has been overdone; he may have embarked less picturesquely, without the chains, in the ordinary course of events after making a small fortune at Macao. The ship was wrecked on shoals off the coast of Cambodia near the river Mekong, and Sousa and 23 others were the sole survivors. It was here that Dinamene perished. Camões is represented as swimming ashore holding the *Lusiads* above his head, like Caesar with his Commentaries. The survivors were taken by a passing ship to Malacca and Goa (1559). Camões at Goa addressed some octaves to the viceroy (1558-61) Dom Constantino de Braganza. By his successor, the Conde de Redondo (1561-64), Camões' poetical talent was appreciated, so much so that they could bandy familiar verse and the poet could beseech the viceroy to save him from a debtor's prison and the tender mercies of the usurer Miguel Roiz, the Skinflint (Fios Seccos). We find the poet inviting young fidalgos as his intimate friends to dinner, and another sign of his favour is the fact that when Garcia da Orta published his great work, the "Coloquios," at Goa, he invited Camões to write a prefatory poem. Redondo, like Mascarenhas, died before his term of office had expired, otherwise he might have made some substantial provision for his poet friend. The next three years are silence. Camões held the reversion to the post of factor at Chaul, but it might be 20 years before it became his. He preferred to return to Portugal.

The friendship of Pedro Barreto, who was proceeding to Sofala as governor, enabled him to leave Goa in Sept. 1567 and go as far as Mozambique in his company. The poet's fortunes had now reached their lowest ebb; he was no longer young, the climate was bad, homeward ships were always overcrowded, and Camões was utterly penniless. He lived on the charity of friends, and was unable to buy himself a new suit of clothes. His spirit was not quite broken; as assets he had his lyrics, his "Parnasso" and his *Lusiads*, and that belief in itself which sometimes supports genius in extremity. He had shown himself very Portuguese in his impulsiveness and he was equally Portuguese in his stubborn persistency. He continued to work at his poems, trusting that they at least might survive. An alleged contemporary account alludes to his "difficult temper"; he had certainly been tried more than most men. In 1569 the historian Couto and some other friends of Camões were delayed at Mozambique by bad weather on their homeward voyage, and when they left they took the poet with them, providing for his food on the way.

He reached Cascaes and Lisbon in April 1570. He found the city stricken by the awful plague of 1569, but his aged mother was still alive. Through the friendly services of the influential Dom Manuel de Portugal he received the royal licence to print the *Lusiads* (Sept. 24, 1571). The poem appeared in 1572 (in two editions) and from March 12 its author was granted an official pension of 15,000 réis. Three and a half centuries later this sum would have been equivalent to half a crown, but in the 16th century, although not munificent, it sufficed to support life. The contrast after the squalor of Mozambique three years before was almost as dramatic as previous reversals in this romantic life. Unfortunately the pension was not always regularly paid, although under the stricter administration of Philip II. it was renewed in favour of the poet's mother, who survived him. A few complimentary verses are all that we know and probably all that were written during the last 10 years of his life. Misfortune had, as he said, frozen his genius. He was not chosen to accompany the young King Sebastian on that last rash and royal throw of the dice in Africa in 1578. The poet, weakened by his 17 years in the East, succumbed to the plague which was once more ravaging Lisbon. There are some reasons to assign his death to the summer of 1579, but the date now generally accepted is 1580, and June 10 is celebrated yearly as a public holiday in his honour in Portugal. On receiving the news of the rout of Alcacer-Kebir, he had written that he was content to die in and with his country. He appears to have died not in his mother's poor house in the Mouraria quarter but in a Lisbon hospital. A Spanish Carmelite friar, Fray José Indio, blessed his departing spirit and shed a tear over the death of "so great a genius without even so much as a sheet to cover him." Camões was buried with other victims of the plague in a common grave. His fame grew and spread gradually through the civilized world. At the third centenary of his death, in 1880, what were assumed to be his remains were removed from the church of Santa Anna and placed beside those of King Sebastian and Vasco da Gama in the national pantheon at Belem.

The life of Camões after his early years at Coimbra was of an unliterary complexion, and his achievement is one of the most extraordinary instances of the triumph of genius over circumstance. The Renaissance had fast hold of him, and, had he lived a life of ease in a library, might have turned him into a pedant instead of merely enriching his verse. The very title chosen for his epic, *Os Lusíadas* ("the Portuguese") was a piece of early pedantry. His world travels and adventures at a time when he had lost little of his first sensitiveness but was old enough to have a philosophical outlook enabled him to transfer his delicate subjectivity to the objects that confronted his eyes as they had confronted the heroes of the preceding century of whom he sang, and this made him a lyric-epic poet, a great painter of the sea, capable of infusing his soul's intensity and personal fervour into objective descriptions. All his greatest poetry was written before he was 40; it is the lyrics composed between the ages of 18 and 32 that cause him to rank with the world's greatest poets, and the greater part of the *Lusiads* belongs to the same period. Some critics hold that he brought the idea of an epic poem on Portugal's achievements with him from Coimbra. The epic idea was indeed in the air in the 16th century and proved a thorn in the side of more than one lyric poet, who like Ronsard, would have preferred to sing quietly of his love without the importunate claims of a *Franciade*. Camões' exile, taking him over the ground of the maritime discoveries of two generations earlier, enabled him to harness his lyrical genius to the epic form and to make his poem of a nation a living work.

It is possible to judge the *Lusiads* by comparison with their model the *Aeneid* (for, although Camões had Homer also in his thoughts, his epic is mainly Virgilian) or by comparison with the "Araucana" of Ercilla and the multitude of lengthy epics that followed. The latter comparison brings out the immeasurable superiority of the *Lusiads*; even Ercilla's epic by its side is a wooden narrative of historical fact, while the tedious and innumerable Portuguese epics which continued into the 19th century are an involuntary but emphatic tribute to the genius of Camões. By comparison with the epic of the ancients what must strike all

critics is Camões's originality. He has made a new thing. If, in the words of Montesquieu, it contains something of the charm of the *Odyssey* and of the magnificence of the *Aeneid*, it was essentially an artificial Renaissance epic such as only genius and exceptional circumstances (lacking in Ronsard's case) could justify. Running counter to the precepts of Politian, Camões chose a recent historical subject, the voyage of Gama (1497-99). The Portuguese adventurers are revealed after they had rounded the Cape of Good Hope and were approaching Mozambique. They are favoured by Venus but have to count on the malignant hostility of Bacchus (for Camões, in the spirit of Renaissance poetry, introduced the pagan gods into his epic). It is not until the sixth stanza that they reach Calicut. In the meantime occasions have been devised to work in the earlier part of the voyage from Lisbon round the Cape, which is personified in the giant Adamastor, and much of the history of Portugal, including the romantic fate of Inês de Castro and the victory of Aljubarrota. The account of the return voyage to Portugal is varied by a sojourn in an imaginary island where the "Lusiads" are welcomed by the Nereids and Tethys foretells the deeds of the Portuguese during the next 50 years. It is this skilful working in of the contemporary and past history of the nation that gives to the poem its balance and unity. Vasco da Gama, the nominal hero, is less an individual than a representative of the Portuguese nation. The length of the *Lusiads* is less than a quarter of that of the epics of Ariosto and Balbuena. In this restraint the poet showed his wisdom, although an early Portuguese admirer of the poem complained that it was too long to be inscribed in gold and too short to be read for ever. Camões' lyric inspiration maintained the *Lusiads*, despite some minor blemishes, at a level attained by no other modern epic (if we except *Paradise Lost*).

A sensitive genius can only make pearls of the harsh strokes of destiny and build song out of sorrow at a cost; it burns itself out, and when Camões returned to Lisbon he seems to have been little more than a sack of ashes, with an occasional glow running through them. His first poems, one or two of them written before he left Coimbra, show that he early attained a perfection of form previously unknown and subsequently unsurpassed in the poetry of his countrymen, an astonishing mastery of the Italian metres; sorrow, suffering and exile gave the poems written during the first years at Goa, including the poem on the "Discontent of the World" and the 73 quintilhas (octosyllabic stanzas of five lines) beginning "Sobolos rios," a deeper thought and philosophy, while the early command of metre and musical rich transparent style were retained. This humanist's mind was of a national cast, and he excelled in the native "redondilhas" (octosyllabic verse). He embraces a wide range of poetry, from feathery light love lyrics to profound musings on change and destiny and the solemn accents of religion; from the satire of circumstance or passing compliments to the heroic sound and fury of patriotic enthusiasm. His poetry combines softness and vigour, thought and ecstasy, Platonic or neo-Platonic mysticism and the most realistic experience, spontaneous naturalness and technical perfection, rich latinization of language and a severe classical restraint. The diction of the *Lusiads* is marked by a flowing grace and majestic harmony. A few of the sonnets, canzoni, eclogues and elegies and half a score of poems written in the native octosyllabic metre have been surpassed by not more than six or seven poets since Homer sang, and are as enduring a title to fame as the composition of the *Lusiads* itself. No authentic contemporary portrait of Camões is extant, and implicit faith cannot be placed in that published by Severim de Faria in 1624. The fate of the lyrics has been unfortunate; they remained in manuscript during the poet's life, and no critical edition has yet been published.

**BIBLIOGRAPHY.**—The immense bibliography of Camões is studied in vols. v., xiv. and xv. of Innocencio da Silva's *Diccionario Bibliographico* and in Theophilo Braga's *Bibliographia Camoniana* (Lisbon, 1880). The text remains that of the complete but uncritical edition in six volumes by the Visconde de Juromenha (Lisbon, 1860-69), but there is a critical edition of the *Lusiads* by Epiphanyo Dias in 2 vols. (Porto, 1920). Valuable contributions to the study of the text were made by C. Michaëlis de Vasconcellos in the *Zeitschrift für romanische Philologie* and *Circulo Camoniano* (1890-92); and important but much discussed documents vitally affecting the biography have been

published by Sr. Pedro de Azevedo in the *Boletim da Segunda Classe* of the Lisbon Academy of Sciences, vol. xi. (1917) pp. 24-25, Sr. Jordão de Freitas in *O Naufragio de Camões* (Lisbon, 1915) and Sr. João Grave in the *Boletim*, vol. xi. (1918) pp. 1041-48. These and other researches and conjectures make it now possible to rewrite in great part the lives by Burton, *Camões: His Life and His Lusiads* (1881), Storck, *Luis de Camoens Leben* (Paderborn, 1890, with Portuguese translation by C. Michaëlis de Vasconcellos, 1897), and Braga, *Camões. Epoca e Vida* (Porto, 1907). Among English translations of the poems, those by Aubertin, *The Lusiads*, 2nd ed. 1884, and seventy sonnets (1881); Burton (*The Lusiads*, 1880, and *The Lyrics*, 1884), and the earliest (1665) English version of the *Lusiads* by Sir Richard Fanshawe still hold the field. The fourth centenary of the poet's birth elicited no work of importance, but a short life of Camões was published by the Hispanic Society of America in 1923. In 1921 had appeared the Lisbon National Library facsimile edition of the *editio princeps* of *Os Lusiadas*, with an introduction by Dr. José Maria Rodrigues, whose important *As Fontes dos Lusiadas and Camões e a Infancia Maria* saw the light in the monthly *Instituto* (1908-13). To the Conde de Ficalho's *A Flora dos Lusiadas* (1880) was added Professor Pereira da Silva's study on *A Astronomia dos Lusiadas* (1918). (A. B.)

**CAMORRA**, a secret or quasi-secret society of South Italy, once of considerable dimensions, but now extinct. It became known publicly about 1820. The origin of the name is unknown, but possibly both the word and the association were introduced into Naples by the Spaniards. There is a Spanish word *camorra* (a quarrel), and similar societies seem to have existed in Spain a long time before the Camorra made its first appearance in Naples.

The society was primarily social, and originated in Neapolitan prisons filled with the victims of Bourbon misrule and oppression, its first purpose being the protection of prisoners. In or about 1830 the Camorra was carried into the city by prisoners who had served their terms. The members worked the streets in gangs. They had special methods of communicating with each other. They mewed like cats at the approach of the patrol, and crowed like cocks when a likely victim approached. A long sigh gave warning that the latter was not alone, a sneeze meant he was not "worth powder and shot," and so on. The society rapidly extended its power, and its operations included smuggling and blackmail of all kinds in addition to ordinary road-robberies. Its influence grew to be considerable. Princes were in league with and shared the profits of the smugglers: statesmen and dignitaries of the church, all classes in fact, were involved in the society's misdeeds. The general disorder of Naples was so great and the police so badly organized that merchants were glad to engage the Camorra to superintend the loading and unloading of merchandise. As it was non-political, the government did not interfere with the society; indeed its members were taken into the police service and the Camorra sometimes detected crimes which baffled the authorities.

**Political Influence.**—After 1848 the society became political. In 1860, when the constitution was granted by Francis II., the *camorristi* then in gaol were liberated in great numbers. The association became all-powerful at elections, and general disorder reigned till 1862. Thereafter severe repressive measures were taken to curtail its power. In Sept. 1877 there was a determined effort to exterminate it: 57 of the most notorious *camorristi* being simultaneously arrested in the market-place. In 1900 revelations as to the Camorra's power were made in the course of a libel suit, and these led to the dissolution of the Naples municipality and the appointment of a royal commissioner. A government enquiry also took place. As the result of this investigation the Honest Government League was formed, which succeeded in 1901 in entirely defeating the Camorra candidates at the municipal elections.

**The Camorra Extinct.**—In 1911 general interest was again aroused in the Camorra by a famous murder case, the Cuocolo murder, in which some 20 persons were brought to trial, all accused of being affiliated to the society, among them the man reputed to be its chief, who was extradited from the United States. The case, which lasted over a year, was transferred from Naples to Viterbo to ensure an impartial verdict, and the severe sentences which were passed dealt a death-blow to the organization.

The term is now used in Naples, as *apaches* is in France or *thugs* in America, to signify that criminality which exists in all great cities.

**CAMOUFLAGE.** The word camouflage, in the broad sense of military deception, is applicable to all stratagems designed to mislead the enemy. In the following account it is used in the restricted sense of deception practised by artists.

### MILITARY

The application to war of camouflage, as thus defined, is by no means novel; dummy guns have been successfully employed to mislead an opponent on occasion ever since guns became a normal part of military equipment. Many historical instances could be brought forward in which camouflage was practised by individuals as an expedient. But it was not till the World War that it was practised by armies as a policy.

A transitional stage between the spasmodic use of camouflage in emergencies and its regular and systematic use is marked by the painting, or other treatment, of coast defence forts to blend with their surroundings, in order to render them less conspicuous from the sea. The well-known chequered black-and-white of the Spithead forts was an attempt to mislead the enemy as to the exact location of the gun embrasures.

A further stage was reached in the adoption of uniforms coloured to blend with the usual or typical colours of the countryside in a theatre of war. The first of these was the Indian khaki uniforms; and after the experience gained in the South African War, when the importance of concealment came into great prominence, the British and most other armies adopted dust-coloured, light-blue, grey or grey-green uniforms.

Hitherto deception in war had been limited to the comparatively simple task of deceiving the human eye, at a considerable distance and for a short time. In the World War its rôle was extended to circumventing the camera in addition to deceiving for long periods the eyes of observers armed with powerful glasses, and for the first time in history a military unit was organized for the definite purpose of practising scientific deception.

This policy was initiated by certain French artists serving in a French battery towards the end of 1914. The interest of a French commander was aroused and his sympathy enlisted, with the result that a "section de camouflage" was formed early in 1915, for the purpose of assisting units in the concealment of battery positions and other military works, and the construction of concealed posts of observation. The success attained by this section led to the organization of the British camouflage service, as a unit of Royal Engineers, early in 1916.

Principles and practice may be dealt with under three heads: (1) the concealment of gun positions and the like from the enemy's aeroplanes; (2) the concealment of observation posts and machine-gun emplacements from direct view; and (3) miscellaneous applications of camouflage.

### PROTECTION AGAINST AIR OBSERVATION

The purpose of camouflage is to render objects indistinguishable or unrecognizable by means of imitation or disguise. Concealment in the limited sense of "hiding from view" is not the primary aim. The ideal is non-interference with the natural or normal aspect of the locality as viewed from the air, with which the enemy has become familiar through observation and photography, the latter being the more accurate. A photograph will always record something. The art of camouflage lies in conveying a misleading impression as to what that something signifies. The photograph records colours and accidents of ground (such as bare earth, vegetation, woods, etc.) in terms of light and shade, forming a patchwork or pattern of black and white meeting in varying intensities of grey. A cultivated district presents a regular chess-board pattern, with large rectangular expanses of monotone, the only accidents to break the monotony being large hedges, banks or houses, with their attendant shadows. Broken ground, such as demolished villages, shelled areas or patchy vegetation, presents a highly complex pattern, full of merging lights and shades.

Photographically, the effect of colour is not so marked or

important as the effect of light and shade. Earth is toward the white end of the scale and grass or vegetation toward the black—not because of their respective colours but on account of the amount of contained shadow or "texture." Contrasts in tone are much accentuated on snow and the effects of shadows are more marked. Consequently it is essential, when judging the colours of a locality, to view it vertically and not obliquely as one is accustomed to see a flower bed.

Therefore the most practical method of planning the concealment of any work is to plan it with reference to a recent photograph which records the ground pattern, and the natural facilities for concealment which exist in the locality. Such facilities abound in a neighbourhood the photographic pattern of which is complex. Any slight error in exact reproduction may escape notice in the prevailing complexity, because detection depends on comparison and comparison is made difficult by the intricacy of the pattern.

There are certain characteristic clues which betray new work to the reader of aerial photographs. They are disturbance of soil, tracks, shadows, regularity and blast marks of guns. To achieve success these clues must be suppressed from the very beginning; conversely, if deception is to be achieved by the use of dummies, these clues must be supplied.

**Shadows.**—The form of any erection, or excavation, is revealed in a photograph by the shape of the shadow cast. Two intersecting planes, e.g., the two sides of the roof of a building, will show differently on the photograph (except for a very brief period every day) because they receive light at different angles, and therefore reflect it differently. It follows that an artificial reproduction of locality must be erected parallel to the contours of that locality, or in other words the planes of the imitation and the real must not intersect. A mound must be imitated by a mound, and a flat surface by a flat surface. Any departure from this principle is most easily detected in a photograph taken when the sun is low, the shadows being long in consequence.

**Regularity.**—No shape in nature is of regular outline; consequently anything of a regular shape in a photograph invites scrutiny because it must be the work of human hands. In a battery position, regularity is usually displayed in the geometric shape of the gun-pit and the regular spacing and alignment of the guns.

**Summary.**—To sum up the theoretical conditions which govern the concealment of gun positions, and other works, from the enemy in the air, the material of which the camouflage is composed must at all times appear on the photograph like the object or surface it represents, and likewise appear natural to the observer's eye. As to material, it must be light, strong, impervious to weather, fireproof and easily manufactured. Disturbances of soil, tracks, shadows, blast-marks and regularity must never seem associated with an active gun position or occupied work.

Natural materials such as branches, grass, etc., are of little use for camouflage purposes if protection from view is required for more than two or three days, for, when withered, they become very conspicuous. The most satisfactory cover is afforded by some form of net having an opaque centre of a boldly irregular shape, with a border becoming decreasingly opaque towards the edges. The centre should be only so opaque as to prevent the object underneath (gun or excavation, as the case may be) being visible from the air and the border opaque enough to mask the shadow of the object without casting a shadow itself. Such a cover is erected at a suitable height above the object to be concealed, and parallel with the contour of the ground. It follows that the higher the erection the greater must be the area required to cover object and shadows. Evidence afforded by tracks is perhaps the most difficult of all to eliminate. Positions which are admirably concealed in every other way are betrayed by the tracks leading up to them, so much so that it is often possible to count the number of guns in a battery by the paths leading to each gun-pit and to distinguish between gun positions and other works.

The following afford good illustrations of methods of concealing approaches to positions in the open: (a) Leading the track close past the gun position and on to join an existing track.

the connection to each pit being treated with camouflage material or cut grass, etc. (b) Similarly, but close in front of the gun-pits in order to use the track to hide blast marks. This method has the disadvantage of restricting traffic while the guns are in action. (c) Siting a battery in the midst of an existing network of tracks, taking precautions to reproduce on the camouflage any path interrupted by a gun-pit. It is not practicable to conceal long trenches. If a covering sags or differs materially in tone from its surroundings the mere length and regularity will betray its presence.

**Material and Production.**—The principal desiderata in camouflage material are durability and portability. It is almost inevitable that production must be standardised in the case of operations on a large scale. It is possible to deal individually only with a few special positions and the exterior of observation posts and the like. Square, woven, weather-proofed fish netting provides the most portable foundation. For a field gun 30 ft. x 30 ft. is sufficiently large, as larger sizes than this become unwieldy and difficult to erect. Wire netting is more durable and therefore best suited for large works. Small rolls—30 ft. x 6 ft.—are a convenient size. Open meshed canvas (scrim) is very suitable material for use on the ground and in conjunction with wire or fish netting. Fireproofing should be adopted wherever this is possible.

For coloration, sunproof dyes are the ideal medium, failing this, water paints. Oil paints are a source of danger owing to their tendency to cause spontaneous combustion in stacked material. In order to achieve standardisation it will probably be necessary to adopt four appropriate colorations, viz., all vegetation, all earth and two mixtures of vegetation and earth.

#### PROTECTION AGAINST DIRECT OBSERVATION

The concealment of observation posts, machine-gun nests, etc., is comparatively simple, being merely an adaptation of the craft of theatrical property-making. Natural features may be selected, in places from which good observation can be obtained, and these must be copied exactly. At night, the real is removed and replaced by the imitation, e.g., trees, sand-bags, mile-stones, mounds of earth, chimney-stacks, walls. The copy is a thin outer shell containing a bullet-proof lining in order to give confidence to the occupier. The loopholes, when subject to scrutiny at short range, can be made quite invisible by the use of gauze, which though painted to resemble the exterior of the O.P., remains transparent from the inside. This method should only be adopted when absolutely necessary, because gauze interferes with vision—especially through glasses; in other cases care must be taken to give the loophole an irregular shape.

The following conditions govern the successful employment of such observation posts, particularly in the case of the more elaborate examples such as trees:

1. Concealed access is essential.
2. The works connected with installation must, like other works, be concealed from the air.
3. They should not be erected in places that are normally subject to heavy shelling, for the reason that careful observation will be prejudiced and accidental damage will probably reveal the observation post to the enemy.
4. Provision must always be made to prevent daylight showing behind the loophole, thus rendering it transparent to the enemy.
5. The comfort and security of the observer must always be studied, otherwise the full value of the observation will never be obtained.

Imitation trees can be designed either to accommodate an observer at a good height above the ground or to conceal a long periscope, the user of which is protected in a strong dug-out. In the former case the observer has a better view but is uncomfortably cramped. The periscope is limited in respect of magnification, field of view and clearness of vision, in proportion to its length (*see* PERISCOPE). On the other hand, advantage may be taken of its length to obtain high command with comparative security or increased security with low command. Further, with suitable mountings, it can be used as an instrument of precision in conjunction with map and compass. Provision should always be made to give bullet-proof protection to the

periscope when in use, and to allow of its being lowered for cleaning and safety when not in use.

#### MISCELLANEOUS APPLICATION

The following are examples from the World War. In the dummy attack, series of painted silhouettes made of stout mill-board representing the various postures of advancing troops, were mounted in frames, which could be raised or lowered from places of safety, so as to represent the waves of an attack. This was to draw fire off a real attack. Dummy heads made of papier mâché were used for location of enemy snipers, the exact position of whom could be gauged by producing the alignment of the holes of exit and entry of the sniper's bullet. Sniper costumes painted and garnished with local material enabled a skilful wearer in numerous cases to attain close proximity to the enemy without detection.

The screening of roads from observation by the enemy is not in the province of camouflage, in that no deception is attempted. It is unnecessary to erect a screen which is completely opaque in order effectively to conceal traffic on a road. A screen consisting of wire netting with two-thirds of the surface covered with interlaced strips of canvas is sufficient—especially if a chequered effect of black and white be adopted.

(F. J. C. W.)

#### NAVAL

Camouflage both of large and small ships on various lines, but with the invariable idea of reducing visibility, had been attempted in the British navy for many years before the World War, but without success. The Board of Admiralty then adopted a partial form of camouflage by painting all vessels a light grey as opposed to the black hulls and light upper works previously in force. It was not until 1917, during the height of the submarine peril, that a practical scheme, having a definite end in view and formulated on scientific lines was put forward and officially adopted by the British authorities. It was called for distinction's sake in official documents "dazzle painting"; it embodied entirely new ideas on sea camouflage and was rescued from the early decease which had, in turn, been the fate of each of its predecessors by the fact that its originator was able to supply in large numbers designs to scale, each of which bore out a central idea.

**Object.**—The sole object of dazzle painting was so to distort the normal appearance of a vessel that her actual course became a matter of doubt in the mind of a submarine officer, the estimation of a vessel's true course being the prime factor required to ensure a successful attack.

**Application.**—Dazzle painting was intended primarily for application to merchant ships. These vessels were in far greater need of protection than warships owing to their slow speed and vulnerability and also to the fact that the enemy was making a concerted attack on England's supplies of food and materials essential to the conduct of the World War. A certain number of war vessels were, however, dazzle painted. These were chiefly ships engaged on convoy work, although a certain number detailed for special duties such as mine-laying and patrol service valued this special form of protection. At first sight it would appear impossible to treat a vessel with paint in such a way that an experienced seaman could be deceived as to her actual course, but dazzle-painted ships proved that this could be done. Juxtaposition of violently contrasted colours, black and white predominating, combined in accordance with the laws of perspective, could make it extremely difficult to judge the accurate inclination of a vessel even at a short distance.

**Coloration.**—In the early stages of dazzle painting, a large range of colours was employed to achieve the end in view. Experience showed that this could be attained by a much smaller number, and towards the end of the War, the principal colours in use were black, white and blue, these being employed in varying intensity. A factor which led to the simplification of the colours used was the knowledge that the German naval authorities had introduced the use of colour screens in their submarine periscopes

with a view to reducing the camouflaged ship to a silhouette, and so neutralizing the effect of the colours used. These screens, however, had no effect whatever on a design depending solely on black, white and blue for its contrast. Shortly after its adoption by the Admiralty, dazzle painting was ordered under the Defence of the Realm Act and the whole merchant service was ordered to be painted. Numbers of war vessels operating with merchant ships were also painted: these comprised chiefly convoy cruisers, sloops and destroyers. The 10th Cruiser Squadron, engaged in blockade duties, was also painted. These vessels were specially liable to attack, being at sea for long periods and constantly under slow speed or altogether stopped.

On the introduction of the scheme a considerable volume of maritime opinion was directed against it from lack of a proper grasp of its objects, and because it appeared to render a vessel more conspicuous than it was when painted grey. In point of fact, at the date of the submission of the scheme the proposer, who was on patrol duty in the Channel, had noted that all transports were painted a dead black from water-line to truck. The opposition, however, rapidly disappeared as soon as the objects of the scheme were thoroughly grasped, and the rapidly increasing numbers enabled seamen to judge for themselves the difficulties of accurately estimating the exact courses of dazzle-painted ships met with at sea.

**Extension of Use.**—Soon after the establishment of the Dazzle Department, enquiries were made by the Allied maritime governments as to the efficacy of this new form of defence against the submarine. The French Ministry of Marine attached three officers for training under the new scheme and shortly afterwards set up a similar department in Paris. The U.S. Navy Department asked that an officer might be sent to Washington; shortly after his arrival a Dazzle Department was formed to deal with U.S. shipping. The Belgian Government arranged for all their merchant vessels to be dealt with directly in the British department. Complete sets of plans were forwarded to Italy and Japan.

The number of vessels saved by this device can never be definitely ascertained, but its rapid expansion in practice to all Allied merchant shipping showed that the authorities were satisfied that it played a great part. Approximately 4,000 merchant ships were painted, and upwards of 400 war vessels, engaged principally in convoy and patrol duties, were also painted. The total cost of painting amounted to some £2,500,000.

**CAMOUFLET.** A term used in military mining to designate a mine charge which, when exploded, does not break the surface of the earth. Derived from Latin "*calamo flatus*"—a blast through a reed or pipe—it came to mean a stiffer. This form of mine is used by the defence to destroy the attackers' advancing mine-galleries without forming a crater on the surface, in which the assaulting infantry might make a lodgment. (See further FORTIFICATION and SIEGE CRAFT.)

**CAMP** (from Lat. *campus*, field), a term used more particularly in a military sense, but also generally for a temporarily organized place of food and shelter in open country, as opposed to ordinary housing (see CAMPING-OUT). The shelter of troops in the field has always been of the greatest importance to their well-being, and from the earliest times tents and other temporary shelters have been employed as much as possible when it is not feasible or advisable to quarter the troops in barracks or in houses. The applied sense of the word "camp" as a military post of any kind comes from the practice which prevailed in the Roman army of fortifying every encampment. In modern warfare the word is used in two ways. In the wider sense, "camp" is opposed to "billets," "cantonments" or "quarters," in which the troops are scattered amongst the houses of towns or villages for food and shelter. In a purely military camp the soldiers live and sleep in an area of open ground allotted for their sole use. They are thus kept in a state of concentration and readiness for immediate action, and are under better disciplinary control than when in quarters, but they suffer more from the weather and from the want of comfort and warmth. In the restricted sense "camp" implies tents for all ranks, and is thus opposed to "bivouac," in which the only shelter is that afforded by impro-

vised screens, etc., or at most small *tentes d'abri* carried in sections by the men themselves. For training purposes in peace time, *standing camps* are formed. These may be considered simply as temporary barracks. An *entrenched camp* is an area of ground occupied by, or suitable for, the camps of large bodies of troops, and protected by fortifications.

**Ancient Camps.**—English writers use "camp" as a generic term for any remains of ancient military posts, irrespective of their special age, size, purpose, etc. Thus they include under it various dissimilar things. We may distinguish (1) Roman "camps" (*castra*) of three kinds, large permanent fortresses, small permanent forts (both usually built of stone) and temporary earthen encampments (see ROMAN ARMY); (2) pre-Roman and (3) post-Roman camps, such as occur on many English hilltops. We know far too little to be able to assign these to their special periods. Often we can say no more than that the "camp" is not Roman. But we know that enclosures fortified with earthen walls were thrown up as early as the bronze age and probably earlier still, and that they continued to be built down to Norman times. These consisted of hilltops or cliff-promontories or other suitable positions fortified with one or more lines of earthen ramparts with ditches, often attaining huge size. But the idea of an artificial elevation seems to have come in first with the Normans. Their *mottes* or earthen mounds crowned with wooden palisades or stone towers and surrounded by an enclosure on the flat constituted a new element in fortification and greatly aided the conquest of England. (See CASTLE.)

**CAMPAGNA DI ROMA**, the low country surrounding the city of Rome, bounded on the north-west by the hills surrounding the lake of Bracciano, on the north-east by the Sabine mountains, on the south-east by the Alban hills, and on the south-west by the sea. (See LATIUM and ROME: Province; and, for origin of the name, CAMPANIA.)

**CAMPAGNA, GEROLAMO** (c. 1549–after 1626), Italian sculptor, born at Verona, a pupil and assistant of Danese Cataneo, with whom he worked at Verona and Padua, and whose work in S. Antonio he completed after his master's death in 1573. He was one of the most distinguished sculptors of his age, his work being very decorative, filled with exuberant life and movement, his figures well modelled, his heads sensitive. Most of his work is in Venice. We may mention the bronze statue of St. Anthony in S. Giacomo di Rialto; one of the two colossi at the Zecca (1580); statuary in S. Redentore, in particular a fine crucifix over the high altar (1588); the high altar of S. Giorgio Maggiore, executed in co-operation with his brother Giuseppe (1591–95); the monumental tomb of the doge, Pasquale Cicogna, in the Jesuit church (1595); the high relief of "Christ supported by Two Angels" in S. Giuliano (1606); the high altar of S. Lorenzo (1615–18).

**CAMPAGNOLA, DOMENICO**, Italian painter and engraver, who worked during the first half of the 16th century at Padua. In conjunction with Titian he decorated the Scuola del Santo with a series of frescoes representing the life of St. Anthony. He was also employed on frescoes in the Scuola del Carmine and in palaces of Padua. His name occurs for the last time on Nov. 24, 1562, when he undertook the decoration of a wall in the sacristy of the cathedral. Among his first extant works are some engravings and woodcuts signed and dated 1517 and 1518. He is well known for his pen and ink drawings, many of which were at one time ascribed to Titian. These drawings are not merely sketches or preliminary studies for pictures, but are works complete in themselves. One of the finest examples is a landscape with two youths in the foreground, signed by the artist, in the Malcolm collection at the British Museum (388).

See G. Morelli, *Italian Masters in German Galleries*. For engravings see E. Gallichon, *Gaz. des B. Arts*, xvii. (1864).

**CAMPAGNOLA, GIULIO** (c. 1482–1514), Italian engraver, born at Padua in 1482. He was a youth of great versatility and promise, and while still under 17 showed much skill at painting, engraving and music. He was influenced by Mantegna and Dürer and engraved subjects after Giorgione. His delicate modelling by flicks and dots anticipated stippling.

## CAMOUFLAGE IN MILITARY OPERATIONS

1. Freight cars being disguised by members of the camouflage corps in France. The irregular designs painted on the sides of the cars tend to make them appear part of the surrounding landscape, thus avoiding detection and possible destruction by aircraft or enemy gunfire
2. An artillery gun camouflaged. The use of mats to represent foliage was one of the chief methods of camouflage in the French battle areas
3. A tramp steamer dazzle-painted to confuse hostile craft as to size and outline of the vessel and direction of travel
4. "Pill box" or gunner's nest in France. The raised covering, simulating earth, renders its position inconspicuous. In the background, curtains of camouflage stretched in grove to conceal soldiers from observation by enemy aircraft
5. R.M.S. "Aquitania," camouflaged for use as a troopship in World War. The pattern confuses observation based on knowledge of the vessel
6. H.M.S. "Furious," a warship, with dazzle-painted camouflage. The effect of colour is not so important as that of light and shade

See Kristeller, *Giulio Campagnola*, Graph. Gesellsch., v. (1907); E. Gallichon, *Gaz. des B.-Arts*, xiii. (1862).

**CAMPAIGN**, a military term for the continuous operations of an army during a war or part of a war. The name refers to the time when armies went into quarters during the winter and literally "took the field" at the opening of summer. Its modern usage is, in contrast to a war on the one hand and a battle (*q.v.*) on the other, to cover the operations in a particular theatre of war and during a particular period. It thus constitutes a clearly defined phase of the war as a whole. The word is also used figuratively, especially in politics, of any continuous operations aimed at a definite object, as the "plan of campaign" in Ireland during 1886-87. The word is derived from the Latin *Campania*, the plain lying south-west of the Tiber, *cf.* Italian, *la Campagna di Roma*, from which came two French forms: (1) *Champagne*, the name given to the level province of that name, and hence the English "campaign," a level tract of country free from woods and hills; and (2) *Campagne*, and the English "campaign" with the restricted military meaning.

**CAMPAN, JEANNE LOUISE HENRIETTE** (1752-1822), French educator, the companion of Marie Antoinette, was born in Paris. She was appointed reader to the daughters of Louis XV., and after the sacking of the Tuileries in June 1792 supported herself by establishing a school at St. Germain. The patronage of Hortense de Beauharnais led to Mme. Campan's becoming directress of the academy founded by Napoleon at Écouen for the education of the daughters and sisters of members of the Legion of Honour. The post was abolished at the restoration of the Bourbons. The most noteworthy thing in Madame Campan's system was the place given to domestic economy. Among her writings are *Mémoires sur la vie privée de Marie Antoinette, suivis de souvenirs et anecdotes historiques sur les règnes de Louis XIV.-XV.* (1823), and *De l'Éducation des Femmes*.

See Jules Flammermont, *Les Mémoires de Madame de Campan* (1886).

**CAMPANELLA, TOMMASO** (1568-1639), Italian Renaissance philosopher, was born on Sept. 5, 1568, at Stilo in Calabria, and became a Dominican in 1582. A chance reading of the *De Rerum Natura* of Bernardino Telesio (*d.* 1588), which delighted him by its appeal to nature rather than to authority, led to his defence of Telesio in *Philosophia sensibus demonstrata* (1591). His own opposition to authority necessitated his departure from Naples for Rome and other Italian cities in the following year. On his return in 1598, his implication in a plot to free Naples from Spanish tyranny culminated in his imprisonment for 28 years, during which time he composed his sonnets and prepared most of his philosophical works. When released, Campanella found favour with the pope whose temporal power he had always supported; but on the outbreak of a new conspiracy headed by his pupil, Tommaso Pignatelli, he was persuaded by the pope to go to Paris (1634) where he was well received by Cardinal Richelieu. While preparing a complete edition of his works, he died in Paris on May 21, 1639.

Campanella was well versed in the sciences of his day. In philosophy, he was, like Giordano Bruno (*q.v.*), a follower of Nicholas of Cusa and Telesio. He rejected Aristotelianism for a direct study of man and nature, but he was never entirely free from the mediaeval spirit. Accepting the authority of faith in the sphere of revealed theology, he held that philosophy should be based on experience. The prime fact in philosophy was to him, as to Augustine and Descartes, the certainty of individual consciousness to which he assigned a threefold content—knowledge, will and love, the perfection of these powers, being true religion and union with God. The fact that consciousness contains the idea of God is the one sufficient proof of the divine existence, since the idea of the Infinite must be derived from the Infinite. God is a unity possessing the attributes of the rational soul in a pre-eminent manner. The more remote from God creatures are, the greater their degree of imperfection and not-being, which is characterized by ignorance, impotence and hatred. However, God is immanent in all finite natures and all, even inanimate beings, have a kind of sensibility. Of creatures, the highest are the

angels and human beings, who, by virtue of their reason, are akin to the Divine. Next comes the mathematical world and then the corporeal world of animals, plants and inanimate things.

In natural philosophy, Campanella shakes off this neo-Platonic colouring and, following Telesio, advocates the experimental method and regards heat and cold as the dynamical principles in matter by the strife of which all life is explained. In political philosophy, he maintains the superiority of the Church to the State, and, therefore, the subjection of all temporal government to the pope as the representative of God. In the *Civitas Solis* of 1623 (Eng. trans. in Morley's "Universal Library"), Campanella, obviously under Platonic inspiration, sketches an ideal state based on communism of goods and of wives, and ruled by philosopher-priests who set forth wisdom, love and power as the highest virtues and command manual and military service from each citizen. Thus the ideal state is an artificial organism for the promotion of individual and collective good. On the view taken as to Campanella's alleged complicity in the conspiracy of 1599 depends the question as to whether this system was a philosophical dream, or a serious attempt to sketch a constitution for Naples in the event of her becoming a free city. The *De Monarchia Hispanica* of 1602 (Eng. trans. by E. Chilmead, 1654) contains an able account of contemporary politics, especially Spanish.

**BIBLIOGRAPHY.**—Campanella's chief works apart from those mentioned above are: *De sensu rerum* (1620); *Apologia pro Galileo* (1622); *Realis philosophiae epilogisticae partes iv.* (1623); *Atheismus triumphatus* (1631); *Monarchia Messiae* (1633); *Philos. realis* (1637); *Philos. rationalis* (1638); *Philos. universalis seu metaph.* (1638). His poems were edited by G. Gentile in *Scrittori d'Italia* (1915), 60 of the sonnets being translated from earlier editions by J. A. Symonds in 1878. See also Ancona, *Opere di T. Campanella, scelte, ordinate ed annotate* (2 vols., Turin, 1854) which contains Cypriano's *Vita Campanellae* (1705); Dom. Berti, *Lettere inedite di Campanella*, etc. (1878), and *Nuovi documenti di T. C.* (1881); V. Spampinato, *T. Campanella, Lettere* (Bari, 1927); L. Amabile, *Fra T. Campanella* (3 vols., Naples, 1882); G. Sante Felici, *Le Dottrine filosofico-religiose di Campanella* (Lanciano, 1895); J. **CAMPANIA**, a territorial division of Italy. The modern district (II. below) is of much greater extent than that known by the name in ancient times.

I. *Campani* was the Roman name for inhabitants first of the town of Capua and its district and then for inhabitants of the Campanian plain. The name is pre-Roman and appears with Oscan terminations on coins of the early 4th (or late 5th) century B.C. struck for or by the Samnite conquerors of Campania, whom the name properly denotes, a branch of the great Sabelline stock (*see* SABINI). We know from Strabo and others that the Samnites deprived the Etruscans of the mastery of Campania in the last quarter of the 5th century. Cumae was taken by them in 428 or 421, Nola about the same time, and the Samnite language they spoke, henceforward known as Oscan, spread over all Campania except the Greek cities, though Etruscans remained here and there for at least another century. The mountain warriors took over many Etruscan customs; the haughtiness and luxury of the men of Capua was proverbial at Rome. This town became the ally of Rome in 338 B.C. By the end of the 4th century Campania was completely Roman politically. Certain towns with their territories (Neapolis, Nola, Abella, Nuceria) were nominally independent in alliance with Rome. These towns were faithful to Rome throughout the Hannibalic war. But Capua and the towns dependent on it revolted; after its capture in 211 Capua was utterly destroyed. *See* R. S. Conway, *Italic Dialects* (1897); J. Beloch, *Campanien* (2nd ed. Breslau 1890).

The name Campania, first formed by Greeks from Campani, was not in common use until the middle of the 1st century A.D. Polybius and Diodorus avoid it entirely. Varro and Livy use it sparingly, preferring *Campanus ager*. Polybius (2nd century B.C.) uses the phrase *τὰ πεδία τὰ κατὰ Καπύην* to express the district bounded on the north by the mountains of the Aurunci, on the east by the Apennines of Samnium, on the south by the spur of these mountains which ends in the peninsula of Sorrento, and on

the south and west by the sea, and this is what Campania meant to Pliny and Ptolemy. The geographers of the time of Augustus (in whose division of Italy Campania, with Latium, formed the first region) carried the north boundary of Campania as far south as Sinuessa, and even the river Volturnus, while farther inland the modern village of San Pietro in Fine preserves the memory of the north-east boundary which ran between Venafrum and Casinum. On the east the valley of Volturnus and the foot-hills of the Apennines as far as Abellinum formed the boundary; this town is sometimes reckoned as belonging to Campania, sometimes to Samnium. The south boundary remained unchanged. From the time of Diocletian onwards the name Campania was extended much farther north, and included the whole of Latium. This district was governed by a *corrector*, who about A.D. 333 received the title of *consularis*. It is for this reason that the district round Rome still bears the name of Campagna di Roma. Campania, consisting mainly of a very fertile plain with hills on the north, east and south, and the sea on the south and west, is traversed by two great rivers, the Liris (mod. Garigliano, 105 m. long) and Volturnus (mod. Volturno, 94 m. long) divided by the Mons Massicus, which comes right down to the sea at Sinuessa. The plain at the mouth of the former is comparatively small, while that traversed by the Volturnus is the main plain of Campania. Both of these rivers rise in the central Apennines, and only smaller streams, such as the Sarnus (mod. Sarno) which waters the fertile plain south-east of Vesuvius, Sebethus, Savo, belong entirely to Campania.

The road system of Campania was extremely well developed and touched all the important towns; it is now followed by railways. The most important road centre of Campania was Capua, at the east edge of the plain. At Casilinum, 3 m. to the north-west, was the only bridge over the Volturnus until the construction of the Via Domitiana; and here met the *Via Appia*, passing through Minturnae, Sinuessa and Pons Campanus (where it crossed the Savo) and the *Via Latina* which ran through Teanum, Sidicinum and Cales. At Calatia, 6 m. south-east of Capua, the *Via Appia* began to turn east and to approach the mountains on its way to Beneventum, while the *Via Popilia* went straight on to Nola (whence a road ran to Abella and Abellinum) and thence to Nuceria Alfaterna and the south, terminating at Regium. From Capua itself a road ran north to Vicus Dianae, Caiatia and Telesia, while to the south the so-called *Via Campana* (there is no ancient warrant for the name) led to Puteoli, with a branch to Cumae, Baiae and Misenum: there was also connection between Cumae, Puteoli and Neapolis, and another road to Atella and Neapolis. Neapolis could also be reached by a branch from the *Via Popilia* at Suessula, which passed through Acerrae. From Suessula, too, there was a short cut to the *Via Appia* before it actually entered the mountains. Domitian further improved the communications of this district with Rome, by the construction of the *Via Domitiana*, which diverged from the *Via Appia* at Sinuessa, and followed the low sandy coast; it crossed the river Volturnus at Volturnum, near its mouth, by a bridge, which must have been a considerable undertaking, and then ran, still along the shore, past Liternum to Cumae and thence to Puteoli. Here it fell into the existing roads to Neapolis, the older *Via Antiniana* over the hills, at the back, and the newer, dating from the time of Agrippa, through the tunnel of Pausilypon and along the coast. The mileage in both cases was reckoned from Puteoli. Beyond Naples a road led along the coast through Herculaneum to Pompeii, where there was a branch for Stabiae and Surrentum, and thence to Nuceria, where it joined the *Via Popilia*. From Nuceria, which was an important road centre, a direct road ran to Stabiae, while from Salernum, 11 m. farther south-east but outside the limits of Campania proper, a road ran due north to Abellinum and thence to Aeclanum or Beneventum. Teanum was another important centre: it lay at the point where the *Via Latina* was crossed at right angles by a road leaving the *Via Appia* at Minturnae, and passing through Suessa Aurunca, while east of Teanum it ran on to Allifae, and there fell into the road from Venafrum to Telesia. Five miles north of Teanum a road branched off to Venafrum from the straight course of the *Via Latina*, and rejoined it near

Ad Flexum (San Pietro in Fine). It is, indeed, probable that the original road made the détour by Venafrum, in order to give a direct communication between Rome and the interior of Samnium (inasmuch as roads ran from Venafrum to Aesernia and to Telesia by way of Allifae), but it is difficult to believe that the short cut through Rufrae (San Felice a Ruvo) was not used in ancient times. The 4th and 3rd century coins of Telesia, Allifae and Aesernia are all of the Campanian type.

Puteoli, the chief ancient harbour, was most important in the 2nd-1st century B.C. The harbours constructed by Augustus by connecting the Lacus Avernus and Lacus Lucrinus with the sea, and that at Misenum (the latter the station of one of the chief divisions of the Roman navy, the other fleet being stationed at Ravenna), were mainly naval. Naples also had a considerable trade, but was less important than Puteoli.

The fertility of the Campanian plain was famous in ancient as in modern times; the best portion was the Campi Laborini or Leborini (called Phlegraei by the Greeks and Terra di Lavoro in modern times) between the roads from Capua to Puteoli and Cumae. The loose black volcanic earth (*terra pulla*) was easier to work than the stiffer Roman soil, and gave three or four crops a year. The spelt, wheat and millet are especially mentioned, as also fruit and vegetables; and the roses supplied the perfume factories of Capua. The wines of the Mons Massicus and of the Ager Falernus (the flat ground to the east and south-east of it) were the most sought after, though other districts also produced good wine; but the olive was better suited to the slopes than to the plain, though that of Venafrum was good. The Oscan language remained in use in the south of Campania (Pompeii, Nola, Nuceria) at all events until the Social War, but at some date soon after that Latin became general, except in Neapolis, where Greek was the official language during the whole of the imperial period.

II. Campania in the modern sense includes a considerably larger area than the ancient name, inasmuch as to the *compartimento* of Campania belong the four provinces of Benevento, Naples, Avellino and Salerno, that of Caserta having been absorbed partly by Naples and partly by Rome. It is bounded on the north by the provinces of Frosinone and Rome (Lazio), Aquila (Abruzzi) and Campobasso (Molise), on the north-east by that of Foggia (Apulia), on the east by that of Potenza (Basilicata) and on the south and west by the Tyrrhenian Sea. The area is 5,364 square miles. It thus includes the whole of ancient Campania, a considerable portion of Samnium (with a part of the main chain of the Apennines) and of Lucania, while towards Lazio the boundary is now as it was in ancient times, consisting thus of a mountainous district, the greater part of which lies on the Mediterranean side of the watershed, with the extraordinarily fertile and populous Campanian plain between the mountains and the sea. The low sandy coast, with its lagoons, begins at the mouth of the Liris, and continues (interrupted only by the Monte Massico, which reaches the sea at Mondragone) past the mouth of the Volturno (where important schemes of drainage and reclamation are in progress, extending to Licola) as far as the volcanic district (no longer active) with its several extinct craters to the west of Naples, which forms the north-west extremity of the Bay of Naples. In consequence of the volcanic character of the district there are several important mineral springs which are used medicinally, especially at Pozzuoli, Castellammare di Stabia, and on the island of Ischia.

Pozzuoli (anc. Puteoli) the most important harbour of Italy in the 1st century B.C., is now of small consequence; while Naples is one of the most important harbours of modern Italy, and the cotton-spinning and weaving industry has taken firm root, as also the perfume industry. Beyond it, Torre del Greco and Torre Annunziata, at the foot of Vesuvius, are active trading ports for smaller vessels. Castellammare di Stabia, on the west coast of the gulf, has a large naval shipbuilding yard. Beyond Castellammare the promontory of Sorrento, ending in the Punta della Campanella (from which Capri is 3 m. south-west) forms the south-west extremity of the gulf. The highest point of this mountain ridge, which is connected with the main Apennine chain, is the Monte S. Angelo (4,735 ft.). It extends as far east as

Salerno, where the coast plain of the Sele begins. The south-east extremity of the Gulf of Salerno is formed by another mountain group, culminating in the Monte Cervati (6,229 ft.); and on the east side of this is the Gulf of Policastro, where the province of Salerno, and with it Campania, borders on the province of Potenza. The population (1921) is 3,254,440.

Naples is the chief railway centre: the new main line from Rome runs by Formia and along the coast to Villa Literno, where it turns inland to Aversa, with a branch to Pozzuoli; while the older line runs from Rome through Roccasecca (whence there is a branch via Sora to Avezzano, on the railway from Rome to Castellammare Adriatico), Caianello (junction for Isernia, on the line between Sulmona and Campobasso or Benevento), Sparanise (branch to Formia and Gaeta) and Caserta to Naples. From Caserta, indeed, there are two independent lines to Naples, while a main line runs to Benevento and Foggia across the Apennines. From Benevento railways run north to Vinchiaturro (for Isernia or Campobasso) and south to Avellino. From Cancellò, a station on one of the two lines from Caserta to Naples, a branch runs to Torre Annunziata, and another to Avellino. Naples, besides the two lines to Caserta (and thence either to Rome or Benevento), has local lines to Pozzuoli and Torregaveta (for Ischia) and two lines to Sarno, one via Ottaiano, the other via Pompeii, which together make up the circum-Vesuvian electric line and are in connection with the railway to the top of Vesuvius. The main line for southern Italy passes through Torre Annunziata (branch for Castellammare di Stabia and Gragnano), Nocera (branch for Codola), Salerno (branch for Mercato San Severino) and Battipaglia. Here it divides, one line going east-south-east to Sicignano (branch to Lagonegro), Potenza and Metaponto (for Taranto

and Brindisi or the line along the east coast of Calabria to Reggio), the other going south-south-east along the west coast of Calabria to Reggio. Industrial activity is mainly concentrated in Naples, Pozzuoli and the towns between Naples and Castellammare di Stabia (including the latter) on the east shore of the Bay of Naples.

**CAMPANIFORM**, in architecture, bell-shaped; most commonly used to describe a type of Egyptian capital (*q.v.*) shaped like an inverted bell.

**CAMPANILE**, a bell tower, used in connection with churches or town halls, especially in Italy. The campanile is sometimes attached to the building and sometimes free standing. The earliest campaniles are those of the churches of S. Apollinare in Classe and S. Apollinare Nuovo at Ravenna, variously dated from the 7th to the 10th century. These are simple round towers without decoration and with small, round, arched openings in pairs near the top. The more usual type of square campanile appears frequently from the 10th century onwards, and was apparently developed simultaneously in Rome and Lombardy. It is generally decorated by means of projecting vertical strips, known as pilaster strips, and ranges of arched cornice which divide the tower into several stages. Each stage has openings on all four faces, either single, double or triple-arched; where double or triple arches are used, there is frequently but a single column between the adjacent arches, even when the wall to be carried is of great thickness, so that a bracket capital, between the column and the arches, becomes necessary. The top of the campanile has an arched cornice, little, if any, larger than the cornices below. The roof, in early examples, is usually a pyramid of low pitch, invisible from the ground. This remained the Roman type

throughout the Middle Ages, although many variations occurred. Cornices of pseudo-classic type are frequently used instead of the arcaded cornice, and the top cornice given greater importance by projecting the eaves of the roof. Openings are often large, completely filling the topmost stage with the exception of the supporting piers at the corners. In general, the tendency in Roman examples is towards horizontality rather than verticality of effect. In many instances the horizontal stages formed by the successive cornices are treated alike, with ranges of wall arcades, as in the campanile of S. Giorgio in Velabro (early 12th century). Greater richness was sometimes given by building in fragments of Roman ornament. Other important Roman examples are: S. Prassede, 1080, Santi Quattro Incoronati, 1123, and S. Maria in Trastevere, 1139.

The campanile reached its most highly organized forms in the north. The Lombards were obviously a tower-building people and they found in the campanile a great opportunity. The early tower of S. Satiro in Milan, of the late 9th century, already shows an advanced composition of horizontal stages, arcaded cornices which connect the corner pilaster strips, and arched openings, single below and double above. In the later, and much larger, northern campanile of S. Ambrogio in Milan (early 12th century) semicircular projections like engaged columns break up the stages and give additional vertical lines. The top storey so developed that it gave the effect of a crown to the whole composition—an immense aesthetic advance—and was finally completed by a pyramidal (occasionally conical) spire, even when the tower below was square, in which case the tower was first capped by a balustrade.

The spired and crowned tower became a favourite in Venetia; by the elimination of horizontal cornices and large openings below the belfry stage, every effort was made to develop a sense of height. The Venetian campanile consists of a tall, square, slim shaft, frequently tapered or battered, which rises unbroken to the open belfry at the top. This belfry has one or two stages of arcade, and is often in stone, although the rest of the tower is brick. Above the belfry cornice rises the spire, sometimes square, as in the famous campanile at Venice (lower portion 10th to 12th century, belfry storey 1510). The original building collapsed in 1902 but was rebuilt in 1908 in exact imitation of the old, or octagonal, with pinnacles and spirelets at the corners, as in the campanile of S. Zeno at Verona (12th century). The Venetian type, owing to its perfection, remained in constant use far into the Renaissance period.

Two campaniles of mediaeval Italy do not belong to any of these types. That at Pisa—the famous leaning tower—is a circular structure of great beauty and richness, with a heavy wall surrounded by stages of arcaded galleries. The other is the great campanile of Florence, designed by Giotto, Taddeo Gaddi and others (early 14th century). This remarkable composition uses the Lombard tradition of horizontal stages, but attains a sense of lightness by the daring octagonal corner buttresses and the tremendous enlargement of the belfry stage, which is approximately twice as high as any other. Of unique beauty, also, are the decorative sheathings of coloured marble and the exquisite sculpture that ornaments the lower storeys.

The great height of many of these Italian campaniles is notable. The total height of that at Venice is 320 ft.; at Florence, 275 ft.; of the Palazzo del Signore, Verona, 250 ft.; and at Cremona, 396 feet. With the advent of the Renaissance, and the subsequent popularity of the dome, the use of campaniles, except in Venetia, diminished rapidly.

Interesting modern campaniles are that of the cathedral at Westminster by G. F. Booley, that of the municipal building group at Springfield, Mass., by Pell and Corbett, and that of the University of California, Berkeley, Calif., by J. G. Howard.

Cummings, *Architecture in Italy* (new ed., 1927).

(T. F. H.)

**CAMPANOLOGY**, the art, or science, concerned with bells, bell-ringing, bell-founding, etc. (See BELL.)

**CAMPANULA** (bell-flower), in botany, a genus of plants (family Campanulaceae) containing about 300 species, found in the temperate parts of the northern hemisphere, chiefly in the Mediterranean region. The name is taken from the bell-shaped flower. The plants are perennial, rarely annual or biennial, herbs

with spikes or racemes of white, blue or lilac flowers. Several are native in Great Britain; *Campanula rotundifolia* is the harebell (*q.v.*) or Scottish bluebell; a common plant on pastures and heaths, the delicate slender stem bears one or a few drooping, bell-shaped flowers. Many of the species are grown in gardens for their elegant flowers; the dwarf forms are excellent for pot culture, rockeries or fronts of borders. *C. Medium*, Canterbury bell, with large blue, purple and white flowers, is a handsome biennial, of which there are numerous varieties. *C. persicifolia*, a perennial with more open flowers, is also a well known border plant, with numerous forms. *C. glomerata*, which has sessile flowers crowded in heads on the stems and branches, found native in Great Britain in chalky and dry pastures, is known in numerous varieties as a border plant. There are also a number of alpine species suitable for rockeries. The plants are easily cultivated. The perennials are propagated by dividing the roots or by young cuttings in spring, or by seeds.

**NETTLE-LEAVED BELL-FLOWER**  
(*CAMPANULA TRACHELIUM*), NATIVE TO EUROPE AND ASIA. FOUND IN GREAT BRITAIN, AND NATURALIZED IN NORTH AMERICA

long; the harebell (*C. rotundifolia*) found from Labrador to Alaska and southward to New Jersey, Nebraska and California, and the California bell-flower (*C. prenanthoides*), a delicately beautiful plant, native to wooded mountain slopes from Monterey to southern Oregon. In the north-eastern United States and adjacent Canada the creeping bell-flower (*C. rapunculoides*), the nettle-leaved bell-flower (*C. Trachelium*) and the clustered bell-flower (*C. glomerata*) have become widely naturalized.

**CAMPBELL, ALEXANDER** (1788–1866), American religious leader, was born near Ballymena, County Antrim, Ireland, on Sept. 12, 1788, and was the son of Thomas Campbell (1763–1854), a schoolmaster and clergyman of the Presbyterian "Seceders." Alexander in 1809 after a year at Glasgow university joined his father in Washington (Pa.) where the father had just formed an association "for the sole purpose of promoting simple evangelical Christianity" as a way to the union of the Church. With his father's desire for Church unity the son agreed. He began to preach in 1810, refusing any salary. In 1811 he settled in what is now Bethany (W.Va.) and was licensed by the Brush Run church.

On adopting baptism by immersion in 1812, his father, mother, wife, sister and others following him, he became the leader of the new society called Disciples of Christ or Christians, sometimes nicknamed Campbellites. The purpose of the society was to restore primitive Christianity as the way to the union of all Christians, which they contended was essential to the conversion of the world. He edited *The Christian Baptist*, later *The Millennial Harbinger*, and 60 volumes bear his name on their title pages. He held for days public debates with the Roman Catholic Archbishop J. B. Purcell, of Cincinnati, Robert Owen, Secularist, of Scotland, and others. Campbell was a member of the constitutional convention of Virginia in 1829. He founded Bethany College (W.Va.), being its president until his death, on March 4, 1866.

Garrison, *The Sources of Alexander Campbell's Theology* (1900); Archibald McLean, *Alexander Campbell as a Preacher* (1908); W. T. Moore, *Comprehensive History of the Disciples of Christ* (1909); Peter Ainslie, *Yale Lectures: The Message of the Disciples of Christ for the Union of the Church* (1913).

**CAMPBELL, BEATRICE STELLA** (Mrs. PATRICK CAMPBELL) (1865– ), English actress, was born in London, her maiden name being Tanner, and in 1884 married Captain Patrick Campbell. In 1893 she created the chief part in Pinero's *Second Mrs. Tanqueray* at the St. James's, her remarkable impersonation at once putting her in the first rank of English actresses. She played with Mr. (Sir Johnston) Forbes Robertson (q.v.) in Davidson's *For the Crown*, and in *Macbeth*. Other great parts of hers were in *Magda* and in Shaw's *Pygmalion*.

In 1922 Mrs. Patrick Campbell published an autobiography, *My Life and Some Letters*.

**CAMPBELL, SIR COLIN:** see CLYDE, COLIN CAMPBELL, Baron.

**CAMPBELL, GEORGE** (1719–1796), Scottish theologian, was born at Aberdeen on Dec. 25, 1719, and died there on March 31, 1796. He was principal of Marischal college (1759), and professor of divinity (1771). He is remembered chiefly for his *Dissertation on Miracles* (1763), written in reply to Hume's essay. His other more important works are *Philosophy of Rhetoric* (1776), and *A New Translation of the Gospels* (1778), with critical and explanatory notes.

See a memoir by G. S. Keith prefixed to the posthumous *Lectures on Ecclesiastical History* (1800).

**CAMPBELL, JOHN** (1708–1775), Scottish man of letters, was born at Edinburgh on March 8, 1708, and died on Dec. 28, 1775. He was the author of *Lives of the British Admirals* (4 vols., 1742 and 1744); the *Military History of Prince Eugène and the Duke of Marlborough* (1736); and a *Political Survey of Britain* (2 vols., 1744); and of many contributions to works of reference. Campbell was agent for Georgia (1765–75).

**CAMPBELL, JOHN CAMPBELL, BARON** (1779–1861), lord chancellor of England, the second son of the Rev. George Campbell, D.D., was born on Sept. 17, 1779, at Cupar, Fife. He studied at the United college, St. Andrews. In 1800 he was entered as a student at Lincoln's Inn, and, after a short connection with the *Morning Chronicle*, was called to the bar in 1806, and at once began to report cases decided at *nisi prius*, i.e., on jury trial. Of these *Reports* he published altogether four volumes, with learned notes; they extend from Michaelmas 1807 to Hilary 1816. He changed his circuit from the home to the Oxford, and was made K.C. in 1827. He unsuccessfully contested the borough of Stafford in 1826, but was elected for it in 1830 and again in 1831. In the House he showed an extraordinary zeal for public business, speaking on all subjects with practical sense, but on none with eloquence or spirit. His main object was the amelioration of the law, more by the abolition of cumbrous technicalities than by the assertion of new and striking principles.

Thus his name is associated with the Fines and Recoveries Abolition Act, 1833; the Inheritance Act, 1833; the Dower Act, 1833; the Real Property Limitation Act, 1833; the Wills Act, 1837; one of the Copyhold Tenure Acts, 1841; and the Judgments Act, 1838. All these measures were important and were carefully drawn; but their merits cannot be explained in a biographical notice. His most important appearance as member for

Stafford was in defence of Lord John Russell's first Reform Bill (1831). The following year (1832) found Campbell solicitor-general, a knight and member for Dudley, which he represented till 1834. In that year he became attorney-general and was returned by Edinburgh, for which he sat till 1841.

His political creed was that of a moderate Whig. In Parliament he continued to lend the most effective help to the Liberal party. At this time also he exerted himself for the reform of justice in the ecclesiastical courts, for the uniformity of the law of marriage (which he held should be a purely civil contract) and for giving prisoners charged with felony the benefit of counsel. His defence of *The Times* newspaper, which had accused Sir John Conroy, equerry to the duchess of Kent, of misappropriation of money (1838), is chiefly remarkable for the confession—"I despair of any definition of libel which shall exclude no publications which ought to be suppressed, and include none which ought to be permitted." His own definition of blasphemous libel was enforced in the prosecution which, as attorney-general, he raised against the bookseller H. Hetherington, and which he justified on the singular ground that "the vast bulk of the population believe that morality depends entirely on revelation; and if a doubt could be raised among them that the ten commandments were given by God from Mount Sinai, men would think they were at liberty to steal, and women would consider themselves absolved from the restraints of chastity." But his most distinguished effort at the bar was undoubtedly the speech for the House of Commons in the famous case of *Stockdale v. Hansard*, 1837, 7 C. and P. 731. The Commons had ordered to be printed, among other papers, a report of the inspectors of prisons on Newgate, which stated that an obscene book, published by Stockdale, was given to the prisoners to read. Stockdale sued the Commons' publisher, and was met by the plea of parliamentary privilege, to which, however, the judges did not give effect, on the ground that they were entitled to define the privileges of the Commons, and that publication of papers was not essential to the functions of Parliament. The matter was settled by an act of 1840.

In 1840 Campbell conducted the prosecution against John Frost, one of the three Chartist leaders who attacked the town of Newport, all of whom were found guilty of high treason. In Lord Cardigan's trial before the House of Lords for murder in a duel—in which he was acquitted on a technicality—Campbell made the extraordinary declaration that to engage in a duel which could not be declined without infamy, i.e., social disgrace, was "an act free from moral turpitude," although the law properly held it to be wilful murder. Next year, as the Melbourne administration was near its close, Plunkett, the venerable chancellor of Ireland, was forced by discreditable pressure to resign, and the Whig attorney-general, who had never practised in equity, became chancellor of Ireland, and was raised to the peerage with the title of Baron Campbell of St. Andrews in the county of Fife. His wife, Mary Elizabeth Campbell, had in 1836 been created Baroness Stratheden in recognition of the withdrawal of his claim to the mastership of the rolls. The post of chancellor Campbell held for only sixteen days, and then resigned it to his successor, Sir Edward Sugden (Lord St. Leonards).

In 1842 he published *The Speeches of Lord Campbell at the Bar and in the House of Commons, with an Address to the Irish Bar as Lord Chancellor of Ireland* (Edinburgh). It was followed by the *Lives of the Chief Justices of England, from the Norman Conquest till the death of Lord Mansfield*, a book of similar construction but inferior merit. Meanwhile Campbell spoke frequently in the House of Lords. The 3rd volume of the *Protests of the Lords*, edited by Thorold Rogers (1875), contains no fewer than ten protests by Campbell, entered in the years 1842–45.

During the period 1841–49, when he sat in the House of Lords, he produced *The Lives of the Lord Chancellors and Keepers of the Great Seal of England, from the earliest times till the reign of King George IV.*, 7 vols., which was published in 1849.

On the resignation of Lord Denman in 1850, Campbell was appointed chief justice of the Queen's Bench. In 1859 he was made lord chancellor of Great Britain, probably on the under-

standing that Bethell should succeed as soon as he could be spared from the House of Commons. Campbell died on June 23, 1861.

**BIBLIOGRAPHY.**—*Life of Lord Campbell, a Selection from his Autobiography, Diary and Letters*, ed. by Hon. Mrs. Hardcastle (1881); E. Foss, *The Judges of England* (1848-64); W. H. Bennet, *Select Biographical Sketches from Note-books of a Law Reporter* (1867); E. Manson, *Builders of our Law* (ed. 1904); J. B. Atlay, *The Victorian Chancellors*, vol. ii. (1908).

**CAMPBELL, JOHN FRANCIS**, of Islay (1822-1885), Gaelic scholar, was born on Dec. 29, 1822, and died at Cannes on Feb. 17, 1885. Educated at Eton and at Edinburgh university, he occupied minor government posts, and employed his leisure in collecting, translating and editing the folklore of the western Highlands, taken down from the lips of the natives. His *Popular Tales of the West Highlands* (4 vols., 1860-62) form a most important contribution to the subject. Campbell invented the sunshine recorder used in most of the British meteorological stations.

**CAMPBELL, LEWIS** (1830-1908), British classical scholar, was born at Edinburgh on Sept. 3, 1830, and died Oct. 25, 1908. He was fellow and tutor at Queen's college, Oxford (1855-58), vicar of Milford, Hants (1858-63), and professor of Greek and Gifford lecturer at the University of St. Andrews (1863-94). In 1894 he was elected an honorary fellow of Balliol. As a scholar he is best known by his work on Sophocles (2nd ed. 1879) and Plato (1867) and his *Life and Letters of B. Jowett* (1897-99).

**CAMPBELL, REGINALD JOHN** (1867- ), British divine, son of a United Free Methodist minister of Scottish descent, was born in London, and educated at schools in Bolton and Nottingham, where his father successively removed, and in Belfast, the home of his grandfather. He was already married when in 1891 he went to Christ Church, Oxford, where he graduated in 1895 in the honours school of modern history. He had gone to Oxford with the intention of becoming a clergyman in the Church of England, but decided to enter the Congregational ministry. He became minister of the Union Street Church, Brighton, and became famous there as a preacher. On Joseph Parker's death he was chosen as his successor (1903) at the City Temple, London. Here his weekly sermons attracted large congregations. At the end of 1906 he attracted widespread attention by his advocacy of what was called the "New Theology," a restatement of Christian beliefs to harmonize with modern critical views and beliefs, and published (1907) a book with this title which gave rise to considerable discussion. In 1915 he left the Congregational ministry, and was ordained priest in the Church of England in 1916. He was vicar of Christ Church, Westminster (1917-21), and in 1924 became vicar of Holy Trinity, Brighton.

**CAMPBELL, ROY** (1902- ), South African poet, the son of Senator Campbell of Natal, was educated at Oxford. After roaming about at sea and wandering through Italy, Campbell published in 1924 his poem, *The Flaming Terrapin*. With a joyful exuberance, the poet, in lyrical narrative (which combines both vision and rhetorical power), exalts the instinctive vital force that brings forth intelligent human effort out of apathy and disillusionment. In the *Wayzgoose* (1928), the same vigour and glow appear but with less poetic detail. The poem is a violent satire on the wayzgoose, an annual assembly of South African would-be artists, poets, novelists and thinkers.

**CAMPBELL, THOMAS** (1777-1844), Scottish poet, eighth son of Alexander Campbell, was born at Glasgow on July 27 1777. His father, who was a cadet of the family of Campbell of Kirnan, Argyllshire, belonged to a Glasgow firm trading in Virginia, and lost his money in consequence of the American war. Campbell was educated at the grammar school and university of his native town. In May 1797 he went to Edinburgh to attend lectures on law. He supported himself by private teaching and by writing, towards which he was helped by Dr. Robert Anderson, the editor of the *British Poets*. In 1799, six months after the publication of the *Lyrical Ballads* of Wordsworth and Coleridge, *The Pleasures of Hope* was published. It is a rhetorical and didactic poem in the taste of his time, and owed much to the fact that it dealt with topics near to men's hearts, with the French Revolution, the

partition of Poland and negro slavery. Its success was instantaneous, but Campbell did not follow it up. He went abroad in June 1800, visited Klopstock at Hamburg, and made his way to Regensburg, which was taken by the French three days after his arrival. He found refuge in a Scottish monastery. Some of his best poems, "Hohenlinden," "Ye Mariners of England," and "The Soldier's Dream," belong to his German tour. He spent the winter in Altona, where he met an Irish exile, Anthony McCann, whose history suggested "The Exile of Erin." On the outbreak of war between Denmark and England he hurried home, the "Battle of the Baltic" being drafted soon after. At Edinburgh he was introduced to the first Lord Minto, who took him in the next year to London as occasional secretary.

In 1803 Campbell married his second cousin, Matilda Sinclair, and settled in London. He was well received in Whig society, especially at Holland House. His prospects, however, were slight when in 1805 he received a government pension of £200. Campbell was at this time regularly employed on the *Star* newspaper, for which he translated the foreign news. In 1809 he published a narrative poem in the Spenserian stanza, "Gertrude of Wyoming," with which were printed some of his best lyrics. He was slow and fastidious in composition, and the poem suffered from over-elaboration. In 1812 he delivered a series of lectures on poetry in London at the Royal Institution; and he was urged by Sir Walter Scott to become a candidate for the chair of literature at Edinburgh university. In 1814 he went to Paris, making there the acquaintance of the elder Schlegel, of Baron Cuvier and others. His pecuniary anxieties were relieved in 1815 by a legacy of £4,000. He continued to occupy himself with his *Specimens of the British Poets*, published in 1819, an admirable selection with short lives of the poets; prefixed to it is an essay on poetry containing much valuable criticism. In 1820 he accepted the editorship of the *New Monthly Magazine*, and in the same year made another tour in Germany. Four years later appeared his "Theodoric," a not very successful poem of domestic life. He took an active share in the foundation of the University of London, visiting Berlin to inquire into the German system of education, and making recommendations which were adopted by Lord Brougham. He was elected lord rector of Glasgow university three times (1826-29). In the last election he had Sir Walter Scott for a rival. In 1834 he travelled to Paris and Algiers, where he wrote his *Letters from the South* (printed 1837).

The small production of Campbell may be partly explained by his domestic calamities. His wife died in 1828. Of his two sons, one died in infancy and the other became insane. His own health suffered, and he gradually withdrew from public life. He died at Boulogne on June 15 1844.

Campbell's other works include a *Life of Mrs. Siddons* (1842) and a narrative poem, "The Pilgrim of Glencoe" (1842).

See *The Life and Letters of Thomas Campbell* (1849), edited by William Beattie, M.D.; *Literary Reminiscences and Memoirs of Thomas Campbell* (1860) by Cyrus Redding; *The Poetical Works of Thomas Campbell* (1875), in the Aldine edition of the British poets, edited by the Rev. W. Alfred Hill, with a sketch of the poet's life by William Allingham; and the "Oxford Edition" of the *Complete Works of Thomas Campbell* (1908), edited by J. Logie Robertson. See also *Thomas Campbell* in the Famous Scots Series, by J. C. Hadden, and a selection by Lewis Campbell (1904) for the Golden Treasury Series.

**CAMPBELL, WILLIAM WILFRED** (1860-1919), Canadian poet, was born in Berlin (now Kitchener), West Ontario, the son of a Church of England clergyman, and was himself educated for the ministry, at Wycliffe college, Toronto, and at the Episcopal Divinity school, Cambridge, Massachusetts. In 1885 he was ordained to the priesthood of the Episcopal Church, and three years later was made rector of St. Stephen, New Brunswick; but in 1891 he gave up his parish, and settled in Ottawa, where he entered the Canadian Civil Service. In conjunction with some other young civil servants he conducted a section on literary criticism under the title of the "Mermaid Inn," in the *Toronto Globe*, and he published several volumes of poetry. He had already published *Lake Lyrics* (St. John, N.B., 1889); *Beyond the Hills of Dream* appeared in 1899, and *Collected Poems* in 1905. Three literary dramas, *Mordred and Hildebrand*, which appeared separately in

1895, *Daulac and Morning*, were collected under the title of *Poetic Tragedies* (1908). Campbell also edited the *Oxford Book of Canadian Verse* (1906). His work is characterized by an intense love of nature and by strong patriotic and imperialist sympathies.

Campbell's *Collected Poems* have been edited, with a memoir by W. J. Sykes (1923).

**CAMPBELL**, a city of Mahoning county, Ohio, U.S.A., on the Mahoning river, adjoining Youngstown on the south-east. It is served by the Baltimore and Ohio railroad. The population was 11,237 in 1920 (50.9% foreign-born white), and was 14,673 in 1930 U.S. census. It is a rapidly growing industrial and residential suburb of Youngstown, manufacturing iron and steel, and was formerly called East Youngstown. The city was incorporated in 1914.

**CAMPBELL-BANNERMAN, SIR HENRY** (1836-1908), British prime minister, was born on Sept. 7, 1836, being the second son of Sir James Campbell, of Stracathro, Forfarshire, lord provost of Glasgow. His elder brother James (1825-1908), was Conservative M.P. for Glasgow and Aberdeen universities from 1880 to 1906. He assumed the name of Bannerman in 1872, on inheriting a Kentish property from his maternal uncle, Henry Bannerman. He was educated at Glasgow university and at Trinity college, Cambridge (senior optime, and classical honours); was returned to parliament for Stirling Burghs (the constituency which he represented uninterruptedly until his death) as a Liberal in 1868 after an unsuccessful attempt at a bye-election; and became financial secretary at the War Office (1871-74; 1880-82), secretary to the Admiralty (1882-84), and chief secretary for Ireland (1884-85). Campbell-Bannerman was one of the few chief secretaries who retired from that difficult office with an enhanced reputation. He had the wisdom, according to Parnell, of leaving things alone. When Gladstone suddenly adopted the cause of Home Rule for Ireland, he "found salvation," to use his own phrase, and followed his leader. In Gladstone's 1886 ministry he was secretary for war, and filled the same office in the Liberal ministry of 1892-95. In the latter year he was knighted (G.C.B.). His administration at the War Office was an excellent one; among other reforms was the establishment of a 48-hour week at Woolwich Arsenal. He arranged the delicate matter of the resignation of the duke of Cambridge as commander-in-chief with the minimum of friction with the court. On the very day on which the duke's retirement was announced the Rosebery government were defeated on a snap vote on a motion to reduce the salary of the secretary for war on account of inadequate reserves of cordite. Although he was nominally responsible for the fall of the Government, Sir Henry had earned the general respect of all parties, and in April 1895, when Mr. Speaker Peel retired, his name was suggested for the chair. He would have liked to have the post (he would have been an admirable Speaker), but his colleagues were averse from his retirement from active politics and he agreed to the selection of Mr. Gully.

The divisions among the parliamentary opposition were acute and notorious. Lord Rosebery had given as the reason for his resignation of the leadership of the Liberal Party (Oct. 6, 1896) the internal difficulties among his followers. No official party leader had been adopted, though Kimberley was leader of the opposition in the House of Lords, and Harcourt in the House of Commons. But the differences in the party were accentuated by a divergence of opinion about the policy of the Government in the Transvaal negotiations. On Dec. 14, 1898, Harcourt resigned from the leadership, and was succeeded in the House of Commons by Campbell-Bannerman. Two months later (Feb. 6, 1899) a party meeting of members of parliament held at the Reform club, confirmed the choice of Campbell-Bannerman, the names of Sir Henry Fowler and of Asquith, which had been suggested in some quarters, being withdrawn. In accepting the office, at that time a very ungrateful one, Campbell-Bannerman concentrated his efforts on keeping the party together in spite of the pronounced differences among its members. These differences were accentuated on the outbreak of the Boer War, to which Campbell-Bannerman himself was strongly opposed. In a speech made at Ilford (June

17, 1899), he had said that "he could see nothing in what had occurred to justify either war-like action or military preparation," and in speeches delivered later he criticized the diplomacy of the Government before the war. Nevertheless, on the outbreak of war, he at once offered to facilitate the grant of supplies, and after the Black Week of Dec. 10-19 he urged courage and new efforts for the prosecution of the war. From the beginning he maintained that peace must be based on the restoration to the conquered states of the rights of self-government and on the co-operation of the British and Boer races in South Africa. In the later stages of the war he denounced the methods employed against the Boers—"this stupid policy of farm-burning devastation and sweeping of women and children into camps." On June 14, 1901, he said at a banquet of the National Reform Union, "When was a war not a war? When it was carried on by methods of barbarism in South Africa." The use of this phrase brought about a crisis in the party, but nevertheless Campbell-Bannerman's leadership was confirmed at a meeting at the Reform club on July 9, which included Asquith and Sir Edward Grey, two of the principal leaders of the imperialist wing.

With the end of the war in 1902 the political conflict assumed a more normal form, and Campbell-Bannerman's difficulties within his own party were simplified by Joseph Chamberlain's adoption of the new fiscal policy, to which the Liberal Party were unanimous in their opposition. It was not, however, Campbell-Bannerman, but Asquith who led the free trade campaign in the country. Campbell-Bannerman, in developing the general Liberal programme with a view to the coming general election, advocated various measures of social reform, but made a special point of criticising the Government expenditure, and of the need of retrenchment. The other principal plank in his programme was the limitation of the veto of the House of Lords. On Home Rule opinion in the party was divided. Many prominent Liberals, including Sir Edward Grey and Asquith, said that the victory at the coming election would not be gained on Home Rule and that a Liberal Government would have no mandate for Home Rule. Campbell-Bannerman secured relative unity by restating his belief in Home Rule (Stirling, Nov. 23, 1905), but admitting that there would not be an immediate opportunity. The terms of this pronouncement had been previously agreed with some of the Liberal imperialists. On Dec. 4, 1905, the Unionist Government resigned, and the king sent for Campbell-Bannerman, who, in a few days, formed his cabinet with the support of all the Liberal leaders, with the exception of Lord Rosebery. The Liberal League (the imperialist section) were represented by Asquith (chancellor of the exchequer), Sir Edward Grey (foreign secretary), and Haldane (secretary of state for war). The Radical wing was represented by John Morley (secretary for India), Lloyd George (president of the Board of Trade), and others. It had been suggested in some quarters that Campbell-Bannerman should himself go to the House of Lords, but he determined to remain in the Commons, and thus maintain effective leadership of the party. The new Government was confirmed in office by an overwhelming majority at the general election of Jan. 1906; the Liberals numbered 377, Labour 53, Nationalists 83 and Unionists 157.

Once prime minister, Campbell-Bannerman's personal popularity proved to be a powerful unifying influence in a somewhat heterogeneous party; and though the illness and death (Aug. 30, 1906) of his wife (daughter of Gen. Sir Charles Bruce), whom he had married in 1860, made his constant attendance in the House of Commons impossible, his domestic sorrow excited widespread sympathy and appealed afresh to the affection of his political followers. This became all the more apparent as his own health failed during 1907; for, though he was obliged to leave much of the leadership in the Commons to Asquith, his possible resignation of the premiership was strongly deprecated; and even after November, when it became clear that his health was not equal to active work, four or five months elapsed before the necessary change was effected. Personal affection and political devotion had in these two years made him appear indispensable to the party, although nobody ever regarded him as in the front line of English statesmen so far as originality of ideas or bril-

liance of debating power were concerned. His strength lay in his sincerity and independence of judgment and in the courage which enabled him to take the unpopular side if he was convinced that it was the right one. From the beginning of the session of 1908 it was evident, however, that Asquith, who was acting as deputy prime minister, would before long succeed to the Liberal leadership; and on April 5 Campbell-Bannerman's resignation was formally announced. He died on the 22nd of the same month. He had spoken in the House of Commons on Feb. 13, but since then had been prostrated and unable to transact business, his illness dating really from a serious heart attack in the night of Nov. 13 at Bristol, after a speech at the Colston banquet.

For the history of the Campbell-Bannerman ministry, which saw the beginning of the struggle between the two houses of parliament and the passage of many useful domestic measures, see ENGLISH HISTORY. The policies in which the prime minister himself was most keenly interested and in which he was a prime mover were the grant of responsible government to the Transvaal and the Orange River Colony, and the reversal of the Taff Vale decision by the passage of the Trades Disputes Act (1906).

See J. A. Spender, *The Life of the Rt. Hon. Sir H. Campbell-Bannerman*. G.C.B. (1923).

**CAMPBELTOWN**, royal and municipal burgh, parish and seaport, Argyllshire, Scotland. Pop. (1931) 6,309. It is situated on a fine bay, towards the south-east extremity of the peninsula of Kintyre, 11 m. N. E. of the Mull and 83 m. S. W. of Glasgow by water. The seat of the Dalriad monarchy in the 6th or 7th century, its importance declined when the capital was transferred to Forteviot. No memorial of its antiquity has survived, but the finely sculptured granite cross standing on a pedestal in the market-place belongs to the 12th century, and there are ruins of old chapels and churches. It became a royal burgh in 1700. One of the churches occupies the site of a castle of the Macdonalds. The staple industry is whisky distilling. The port is the head of a fishery district. Shipbuilding, malting and net-making are other industries, coal is mined in the vicinity, and limestone quarried. There are three piers and a safe harbour. On the Atlantic shore is the well-known golf-course of Machrihanish, 5 m. distant. Machrihanish is connected with Campbeltown by a light railway. On the rock of Dunaverty stood the castle of Macdonald of the Isles, who was dispossessed by the Campbells in the beginning of the 17th century. At this place in 1647 General David Leslie is said to have ordered 300 of the Macdonalds to be slain after their surrender. Of the ancient church founded here by Columba, only the walls remain.

**CAMPE, JOACHIM HEINRICH** (1746-1818), German educationalist, born at Deensen, Brunswick, became director of studies in the Philanthropin at Dessau (see BASEDOW). He started an educational establishment of his own near Hamburg, but in 1783 gave it up on account of ill-health. In 1787 he proceeded to Brunswick as counsellor of education, and purchased the Schulbuchhandlung. Among the most popular of his numerous educational works were the *Kleine Kinderbibliothek* (11th ed., 1815); *Robinson der Jüngere* (59th ed., 1861), translated into nearly every European language; and *Sämmtliche Kinder- und Jugendschriften*, 37 vols.

**CAMPECHE**, a southern State of Mexico, comprising the western part of the peninsula of Yucatan, bounded north and east by Yucatan south by Guatemala, south-west by Tabasco and north-west by the Gulf of Mexico. Pop. (1921) 76,419, mostly Indians and mestizos. Area, 19,672 sq.m. The name of the State is derived from its principal forest product, *palo de campeche* (logwood). The surface, like that of Yucatan, consists of a vast limestone plain, broken by a group of low elevations in the north, heavily forested in the south, but with open tracts in the north adapted to grazing. The northern part is insufficiently watered, the rains filtering quickly through the soil. In the south, however, there are some large rivers, and the forest region is very humid. The climate is hot and unhealthy. In the north-west angle of the state is the Laguna de Términos, a large tide-water lake, which receives the drainage of the southern districts. Among the products and exports are logwood, fustic, lignum-vitae,

mahogany, cedar, hides, tortoiseshell and *chicle*, the last extracted from the *zapote chico* trees (*Achras sapota*, L.). Stock-raising engages some attention. One railway crosses the State from the capital, Campeche, to Mérida, Yucatan, and there are several other short lines. The rivers of the south are much used in the transportation of products. The port of Carmen (pop. in 1900, about 6,000), on a sand key between the Laguna de Términos and the Gulf, has an active trade in dyewoods and other forest products, and owing to its inland water communications with the forest areas of the interior is the principal port of the State.

**CAMPECHE or CAMPECHE DE BARANDA**, a port of Mexico, and capital of a State of the same name, situated on the bay of Campeche, 825m. E. of the City of Mexico and 90m. S.W. of Mérida, in lat. 20° 5' N., long. 90° 16' W. Pop. (1910) 16,775; (1921) 16,938. Campeche was one of the three open ports of this coast under the Spanish régime, and its walls, general plan, fine public edifices, shady squares and comfortable stone residences are evidence of the wealth it once possessed. It is still one of the most attractive towns on the gulf coast of Mexico. It had a monopoly of the Yucatan trade and enjoyed large profits from its logwood exports, both of which have been largely lost to Progreso, the port of Mérida. The harbour of Campeche is a shallow roadstead and vessels drawing more than 9ft. are compelled to lie outside and discharge cargo into lighters. The exports include logwood, cotton, hides, wax, tobacco, salt and cigars of local manufacture. The principal public buildings are the old citadel, some old churches, the town hall, a handsome theatre, hospital and market. The streets are traversed by tramways, and a railway runs north-eastward to Mérida. Campeche stands on the site of an old native town, of which there are interesting remains in the vicinity, and which was first visited by Hernández de Córdoba in 1517. The Spanish town was founded in 1540, and was sacked by the British in 1659 and by buccaneers in 1678 and 1685. During the revolution of 1842 Campeche was the scene of many engagements between the Mexicans and people of Yucatan.

**CAMPEGGIO, LORENZO** (1464-1539), Italian cardinal, was born at Milan. At first he followed a legal career at Pavia and Bologna. In 1510 he went into the Church. For his services during the rebellion of Bologna Julius II. made him auditor of the Rota in 1511 and sent him to Maximilian and to Vienna as nuncio. Raised to the see of Feltre in 1512, he went on another embassy to Maximilian in 1513, and was created cardinal priest of San Tommaso in Pavione in 1517. Leo X., needing a subsidy from the English clergy, sent Campeggio to England in 1518, ostensibly to arrange a crusade against the Turks. Though his mission failed, on his return to Rome Campeggio was received in Consistory in 1519 with the gift from the king of the palace of Cardinal Adriano Castellesi (*q.v.*), who had been deposed. He was made protector of England in the Roman curia; and in 1524 Henry VIII. gave him the rich see of Salisbury, and the pope gave him the archbishopric of Bologna. After attending the diet of Regensburg, he shared the captivity of Clement VII. during the sack of Rome in 1527, and did much to restore peace. On Oct. 1, 1528, he arrived in England as co-legate with Wolsey in the matter of Henry's divorce. He brought with him a secret document, the Decretal, which defined the law and left the legates to decide the question of fact; but this important letter was to be shown only to Henry and Wolsey. "Owing to recent events," that is, the loss of the temporal power, Clement was in no way inclined to offend the victorious Charles V., Catherine's nephew, and Campeggio was instructed to divert the king from his purpose and protract the matter as long as possible. When the legatine court was opened at Blackfriars, on June 18, 1529, the result was certain. Campeggio could not by the terms of his commission give sentence; so his only escape was to prorogue the court on July 23 on the plea of the Roman vacation. Having failed to satisfy the king, he left England on Oct. 26, 1529, after his baggage had been searched at Dover to find the Decretal, which, however, had been burnt. Returning to Bologna, the cardinal assisted at the coronation of Charles V. on Feb. 24, 1530, and went with him to the diet of

Augsburg. He was deprived by Henry of the English protectorate; and when sentence was finally given against the divorce, Campeggio lost the see of Salisbury as a non-resident alien, by act of parliament (March 11, 1535); in 1537 he became cardinal bishop of Sabina, and died in Rome on July 25, 1539.

**CAMPEGNIS, SYMPHORIANUS** (1472-1539), French physician, received his medical training at Pavia, practised at Lyons, and became physician to Charles VIII. and Louis XII. As one of the early humanists, he aimed to harmonize the best elements in Greek and Arabian medicine. Besides his history of medicine, entitled *De Claris Medicinæ Scriptoribus* (Lyons, 1506) and his medical dictionary (Lyons, 1508), Campegnis wrote *Practica Nova* (1517) and *Hortus Gallicus* (1533).

**CAMPER, PETER** (1722-1789), Dutch anatomist and naturalist, was born at Leiden on May 11, 1722. He was educated at the university there, and in 1746 graduated in philosophy and medicine. He was successively professor at Franeker (1750), Amsterdam (1755) and Groningen (1763). In 1787 he was nominated to a seat in the council of state, and died at the Hague on April 7, 1789.

The most important of Camper's works on comparative anatomy were published in 3 vols. at Paris in 1803, under the title *Œuvres de P. Camper qui ont pour objet l'histoire naturelle, la physiologie, et l'anatomie comparée. His Dissertation physique sur les différences réelles que présentent les traits du visage* etc. was published in 1781 both in Dutch and in French. (See also ANATOMY.)

**CAMPHAUSEN, OTTO VON** (1812-1896), Prussian statesman, born at Hünshoven on Oct. 21, 1812, was educated at Bonn, Heidelberg, Berlin and Munich. After a distinguished career in law, he became a councillor in the ministry of finance in 1845 and in 1869 was appointed minister. He had been a member of the second chamber of the Prussian diet since 1849 as a Moderate Liberal. His financial policy aided by the French war indemnity, was successful in restoring the Prussian finances to a flourishing condition, but his liberalism earned him Bismarck's hostility and he was forced to resign. He died in Berlin on May 18, 1896.

**CAMPHAUSEN, WILHELM** (1818-1885), German painter, was born in Düsseldorf on Feb. 8, 1818, and died there on June 18, 1885. He studied under A. Rethel and F. W. von Schadow. As a historical and battle painter he rapidly became popular, and in 1859 was made professor of painting at the Düsseldorf academy. His "Frederick the Great at Potsdam," "Frederick II. and the Bayreuth Dragoons at Hohenfriedburg," and pictures of the Schleswig-Holstein campaign and the war of 1866 (notably "Lines of Düppel after the Battle," in the Berlin National Gallery), made him famous in Germany as a representative of patriotic historical art. He also painted many portraits of German princes, soldiers, and statesmen. He wrote a diary of the Schleswig-Holstein campaign, *Der Maler auf dem Kriegsfeld* (1865), with illustrations.

**CAMPBORS** occur as components of the essential oils of many plants; and are extracted by distilling the plant material with steam; separation of the "camphors" is afterwards effected by fractional distillation, freezing or chemical treatment. The camphors are mainly alcohols and ketones of the hydrocarbons known as terpenes. Commercially, the term "camphor" is generally applied to any solid product so obtained, and hence includes the solid paraffin "stearoptenes" and sesquiterpene alcohols of essential oils. "Camphors" may thus be divided into two main groups, according to the nature of the corresponding hydrocarbon; chemically, however, the term should be reserved for the oxygenated derivatives of terpenes and sesquiterpenes, liquid as well as solid. The commercial camphors are mostly colourless crystalline solids, with characteristic odours; they are sparingly soluble in water, but dissolve readily in alcohol, ether and organic solvents generally. In this article only the chief camphors of technical interest will be mentioned; details as to their chemical structure, synthesis, and relations will be found in the article TERPENES.

*Camphor*,  $C_{15}H_{10}O$ , also known as *Japan* or *laurel camphor*, which constitutes the bulk of the camphor of commerce, is ob-

tained from the camphor laurel (*Cinnamomum Camphora*), a tree flourishing in Japan, Formosa and central China. Camphor occurs also in various other essential oils, e.g., lavender, rosemary, sage and spike. It is obtained by steam-distilling the chopped branches and twigs of the camphor laurel. The crude product, which amounts to about 3% of the wood used, consists of crystalline camphor and camphor oil; the latter, when distilled, yields camphor and other products, notably safrol. The crude camphor, which is refined by sublimation with quicklime and charcoal, then forms a translucent mass of hexagonal prisms, m.p.  $175^{\circ}C$ , b.p.  $204^{\circ}C$ . It has a characteristic odour, and it sublimes very readily. It is very slightly soluble in water, but it dissolves freely in alcohol, ether, etc. Japan camphor (*d*-camphor) is dextrorotatory, with  $[\alpha]_D +44.2^{\circ}$  in a 20% alcoholic solution. The rare laevo-camphor, or *matricaria camphor*, occurs in the oil of *Matricaria parthenium*; it may also be prepared by oxidizing *l*-borneol. The so-called "artificial camphor" is pinene hydrochloride (bornyl chloride); this substance is an intermediate product in the preparation of *dl*-camphor or *synthetic camphor*, which is optically inactive (m.p.  $178.6^{\circ}C$ ), from pinene of turpentine oil (see TERPENES). The main use of camphor is in the manufacture of celluloid; it finds application also in making smokeless powders, and as a disinfectant and medicinal agent. Externally applied it acts as a counter-irritant, and, in some degree, as a local anaesthetic, being also a definite antiseptic. It is therefore used in liniments for the relief of myalgia, sciatica, lumbago, etc.

*Borneol*, *Borneo camphor*, or bornyl alcohol,  $C_{15}H_{17}OH$ , is the dextrorotatory secondary alcohol corresponding to Japan camphor, from which (in company with *l*-isoborneol) it is produced by reduction. It occurs in the wood of *Dryobalanops aromatica*, a majestic East Indian tree, and is known also as Malayan, Barus, or *Dryobalanops camphor*. *d*-Borneol melts at  $204^{\circ}$  and boils at  $212^{\circ}C$ . It has a camphor-like but somewhat peppery odour. *l*-Borneol, sometimes called *Ngai camphor*, or *baldrianic camphor*, occurs in *Blumea balsamifera*.

*Menthol*, or *mint camphor*,  $C_{10}H_{18}OH$ , 5-methyl-2-isopropyl-hexahydrophenol, is obtained from the essential oils of the so-called peppermint (*Mentha piperita*) and its two varieties, the black mint (*M. piperita vulgaris*) and the white mint (*M. piperita officinalis*); in addition, Japanese and Chinese peppermint oils are distilled from *M. arvensis piperascens* and *M. arvensis glabrata*. Crystalline menthol, which was first mentioned by the Dutch botanist Gambius (1771), is obtained by submitting the cooled oil to centrifugalization, preferably after removing the terpenes, etc., by distillation under diminished pressure. Besides unremoved menthol, the residual "dementholized oil" contains *l*-menthone and many other substances. Peppermint menthol (*l*-menthol) is laevo-rotatory; it crystallizes in prisms (m.p.  $43^{\circ}C$ , b.p.  $212^{\circ}C$ ), having the odour and taste of peppermint. It is very slightly soluble in water, but dissolves freely in alcohol, ether, etc. Menthol is used in medicine to relieve pain, as in rheumatism, neuralgia, throat affections and toothache. It acts also as a local anaesthetic, vascular stimulant and disinfectant. Natural *l*-menthol has been replaced to some extent by *dl*-menthol ("synthetic menthol"), prepared by the catalytic hydrogenation of piperitone (*q.v.*) and thymol; this substance is optically inactive and melts at  $34^{\circ}C$  when pure, but otherwise it is practically identical with *l*-menthol in its properties. Other stereoisomeric substances are *d*-menthol (m.p.  $43^{\circ}C$ ), *d*- and *l*-neomenthol (oils), *dl*-neomenthol (m.p.  $51^{\circ}C$ ), *d*- and *l*-isomenthol (m.p.  $81.5^{\circ}C$ ), and *dl*-isomenthol (m.p.  $53.5^{\circ}C$ ).

*Thymol*, or *thyme camphor*,  $C_{10}H_{18}OH$ , 5-methyl-2-isopropyl-phenol, occurs in the essential oils of ajowan (*Carum ajowan*), garden thyme (*Thymus vulgaris*), wild thyme (*T. serpyllum*), horse mint (*Monarda punctata*), etc. It is extracted from such oils by shaking them with an aqueous solution of a caustic alkali; it may also be prepared synthetically from *p*-cymene, piperitone, etc. Thymol forms large colourless plates, m.p.  $44^{\circ}C$ , b.p.  $230^{\circ}C$ . It has a strong odour of thyme, and is freely soluble in alcohol, chloroform, ether, olive oil or alkaline solutions. It is a more powerful antiseptic than phenol, but its slight solubility in water prevents its use for the same purposes. A saturated solution

(1 in 1,000 of warm water), thymol gauze, and an ointment are used. Externally it is antiparasitic, whilst internally it has been used as an intestinal antiseptic in typhoid fever. Its chief use is as an anthelmintic to destroy the *Ankylostoma duodenale*. With iodine and alkali it yields dithymol di-iodide (*aristol*), a substitute for iodoform. *GlycOTHymolin* is a proprietary preparation, used in the treatment of catarrhal conditions of mucous membranes, whilst a mixture of naphthalene, camphor and thymol is sold under the name of *thymolin*.

*Buchu camphor*, or *diosphenol*,  $C_{10}H_{16}O_2$ ,  $\Delta^1$ -menthen-2-ol-3-one, occurs in the leaf-oils of several species of South African *Barosma*, or "Buchu." It forms crystals (m.p.  $83^\circ C$ , b.p.  $232^\circ C$ ) with an odour of mint. (J. Rd.)

**CAMPHUYSEN, DIRK RAFELSZ** (1586–1627), Dutch painter, poet, and theologian, was the son of a surgeon at Gorcum. As he manifested great artistic talent, his brother, in whose charge he was left on the death of his parents, placed him under the painter Govaerts. But at that time there was intense interest in theology, and Camphuysen, sharing in the prevailing enthusiasm, deserted the pursuit of art to become, first, a private tutor and afterwards minister of Vleuten near Utrecht (1616). He embraced the doctrines of Arminius and was deprived of this post and driven into exile (1619). He has left a translation of the Psalms and a number of short pieces, remarkable for their freshness and depth of poetic feeling; but his fame chiefly rests on his pictures, which, like his poems, are mostly small, but of great beauty; the colouring, though thin, is pure; the composition and pencilling are exquisite, and the perspective above criticism. The best of his works are his sunset and moonlight scenes, and his views of the Rhine and other rivers. The close of his life was spent at Dokkum. His nephew Raphael (b. 1598) is by some considered to have been the author of several of the works ascribed to his uncle; and his son Govaert (1624–74), a follower or imitator of Paul Potter, is similarly credited.

**CAMPI, GIULIO** (1502–1572), the founder of a school of Italian painters, was born at Cremona. He was son and pupil of a painter, Galeazzo Campi (1475–1536). He was later taught by Giulio Romano, and made a special study of Titian, Correggio and Raphael. His works are very numerous, and the church of St. Margaret in his native town owes all its frescoes to his hand. Among the earliest of his school are his brothers, Vincenzo and Antonio; the latter was also of some mark as a sculptor and as historian of Cremona.

Giulio's pupil, BERNARDINO CAMPI (1522–1592), in some respects superior to his master, began life as a goldsmith. After an education under Giulio Campi and Ippolito Corta, he attained such skill that when he added another to the 11 Caesars of Titian, it was impossible to say which was the master's and which the imitator's. His principal work is seen in the frescoes of the cupola at San Sigismondo, at Cremona.

**CAMPILLO, JOSÉ DEL** (1695–1743), Spanish statesman. Under the protection of Patiño, who became prime minister in 1726, Campillo was constantly employed on naval administrative work both at home and in America. It was Patiño's policy to build up a navy quietly at home and in America, without attracting too much attention abroad, and particularly in England. In 1741, when Spain was entangled in a land war in Italy and a naval war with England, Campillo was made prime minister. His short tenure of power was chiefly notable for his vigorous attempt to sweep away the system of farming the taxes, which left the State at the mercy of contractors and financiers. He persuaded the king to allow him to establish a system of direct collection, by which waste and pilfering would be avoided. He died on April 11, 1743. Campillo wrote a treatise on a *New System of Government for America* printed at Madrid 1789. He also left a ms. treatise with the curious title, *What is superfluous and is wanting in Spain, in order that it may be what it ought to be, and not what it is*.

See D. Antonio Rodriguez Villa, *Patiño y Campillo* (1882).

**CAMPIN, ROBERT** (1375–1444), a painter of the School of Tournai, formerly known as the Maître de Merode and the

Maître de Flémalle. Campin's name appears in the records of Tournai between 1406 and 1444. It is there stated that he was entrusted with decorative work by the town council. Rogier van der Weyden and Jacques Daret are mentioned as entering his studio as pupils in 1427, though Rogier at that time must have been some 27 years old. Campin died on April 26, 1444. Most of the pictures now ascribed to this master were previously thought to be the early work of Rogier van der Weyden; and Campin's work has only recently been disentangled from that of his famous pupil. His masterpiece is the triptych of the Annunciation in the collection of the countess of Merode at Westerloo-Tongerloo. Another important work is at the Staedel in Frankfurt, consisting of three panels of an altar-piece said to have come from the Abbey of Flémalle. The master of this picture was provisionally called Maître de Flémalle until he was identified with Robert Campin by G. Hulin, who by documentary evidence also identified Campin's pupil, Jacques Daret, as the master of an altar-piece executed for the abbey of St. Vaast, panels of which have survived and are now at Berlin, in Paris and in the Pierpont Morgan collection. Other works which are generally ascribed to Campin are the "Virgin and Child in a Room," National gallery, London (Salting collection); a panel at Frankfurt, said to have formed part of a triptych representing the "Descent of the Cross"; a "Madonna" at the gallery of Aix in Provence; and two heads of "Christ and the Virgin," in the Johnson collection at Philadelphia. To the master's last period belong the wings of an altar-piece at Madrid dated 1438 and painted for Heinrich von Werl, a notable professor at Cologne, and a "Crucifixion" in the Berlin museum.

**BIBLIOGRAPHY.**—G. H. de Loo (Hulin), *Catalogue Critique de l'Exposition à Bruges* (1902); and his article in the *Burlington Magazine* (July, 1909). Maurice Houtard, *Jacques Daret* (1907); A. J. Wauters, "L'Ecole de Tournai" (*Revue de Belgique*, 1908); Friedrich Winkler, *Der Meister von Flémalle und Rogier van der Weyden* (1913); Sir Martin Conway, *The Van Eycks and their Followers* (1921); Max Friedländer, *Der Meister von Flémalle* (1926).

(I. A. R.)

**CAMPINAS**, an inland city of the State of São Paulo, Brazil, 65m. by rail north west of the city of São Paulo and 114m. from the port of Santos, with which it is connected by the Paulista and São Paulo railway. In 1926 the population of the city and municipality was 115,000. Campinas is the commercial centre of one of the oldest coffee-producing districts of the State and the outlet for a rich and extensive agricultural region lying farther inland. The Mogyana railway starts from this point and extends north to Uberaba, Minas Geraes, while the Paulista lines extend north-west into new and very fertile regions. Coffee is the staple production, though Indian corn, mandioca and fruit are produced largely for local consumption. The city is built in a bowl-like depression of the great central plateau, and the drainage from the surrounding hillsides has produced a dangerously insanitary condition, from which one or two virulent fever epidemics have resulted.

**CAMPING** is as old as the human race; for the term may be used not altogether ineptly to refer to the only form of living followed by the original representatives of the human race. For thousands of years they slept, ate, worked and carried on practically all functions of life under the free heavens.

**The United States.**—The American Indian was most successful in making this adaptation. He cherished a fraternal understanding with the elements and mingled in a fanciful, brotherly fellowship with the birds and animals, with the trees and flowers, with the waters and winds. He acquired a practical physical skill hunting, fishing, riding, paddling and fighting; a practical mental acuteness in knowing how to live in the woods or find his way through the forests where others might perish. Camping in its early sense was begun in America by these Indians hundreds of years before the landing of Columbus. It was adopted and altered by the white man during the colonial days and was continued down to the close of the first century after the founding of the republic. During that important century of upbuilding, the people of the United States consisted primarily of open-air men, of farmers in the East and of pioneers in the West. As late as 1880, almost three-fourths of the population was rural.

From this hasty summary of the history of camping, two outstanding facts immediately appear—(1) man's period of outdoor living extended over immeasurable aeons, his period of indoor living over a few brief centuries; hence the modern urge to get out into the unconfined spaces is an ancient racial heritage; indeed, a primeval, perhaps a biological, instinct; (2) man's physical vigour, mental acumen and moral power, were developed largely as a result of his constant, direct and personal contact with nature in her various moods—moods sometimes friendly, often hostile.

When the modern apartment tenant therefore seeks to re-establish contacts with the outdoors, he may be responding knowingly and intentionally to a health-assuring, recreational and educational urge, but responding at the same time, perhaps unknowingly and unintentionally, to an even stronger and more irresistible racial, moral and religious instinct. Certain it is that the farmers and pioneers who constituted approximately 75% of the population of the United States prior to 1880 received the most effective part both of their general all-round training for the work of building up the country and also of their genuine education from the duties involved and from the lessons learned in blazing the trail and driving the covered wagon.

The sons and daughters of these open-air men secured their knowledge of and skill in the handicrafts, in nature lore, in manual training by using the loom in the home, by gathering the herbs and the plants for food or for medicinal purposes, by selecting and fashioning the red oak for their ox-bows or the ash for their basket splints. By living in the woods and mountains where distances are great, they were forced by sheer necessity to develop habits of resourcefulness and self-dependence, habits of economy and appreciation, habits of initiation and co-operation.

After the Civil War the United States changed from an open-air to a housed-in nation. The population was being converted from rural to urban, from agricultural to manufacturing and commercial. By the close of the first quarter of the 20th century, more than half the people lived in cities of 8,000 or over. A generation was growing up that knew not the birds, the trees, the flowers, nor the stars; that knew not how to carry a pack, how to blaze a trail, how to live off the country, how to keep the campfire burning; a generation that was allowing to atrophy the pioneer virtues that the human race had been evolving within itself so slowly and so painfully during its almost unceasing struggle against nature. Hardly, however, had the drift from the country to the city got under way when men associated primarily with the schools and colleges founded agricultural colleges with the purpose of making farm life more attractive. In the '70s, Louis Agassiz was urging his pupils to "study nature, not books"; in the '80s courses in nature lore were being offered in various educational institutions. Soon the back-to-nature movement was making an effective appeal to those interested in health, recreation and education. At the same time opportunities for them to get out into the woods and mountains were being created and multiplied. The increased and wider distribution of wealth afforded them leisure and financial means to travel away from the crowded streets. The growth of rapid and inexpensive transportation facilities, particularly of the through electric lines and the automobile, brought the theretofore distant country nearer. Then the improvement of the highways, the development of the county, State and national parks, the perfection of outdoor sleeping and cooking appliances made it comparatively safe and comfortable for the city dweller to transform himself at least temporarily into an amateur camper.

Private camps for adults began to come into existence during the first decade of the 20th century. They were established by directors of children's camps to provide nearby accommodations for the parents of their boys and girls, and by country boarding-housekeepers who gradually expanded their commercial ventures so as to include some of the health and recreational features of the regularly organized camps. Although a considerable number of these private open-air institutions survive for only a season or two, the growth of the movement has on the whole been rapid. According to conservative estimates there are (1928) in existence almost 400 camps for boys, over 300 camps for girls and about

100 camps for adults, with a total annual membership of approximately 50,000. While a very considerable number of them are in the New England States, particularly in Maine, New Hampshire and Vermont, the movement has spread both toward the West and toward the South until it now extends from coast to coast.

A typical day's programme starts with the bugle call at about 6.45 A.M., followed by a dip in the lake, flag raising, breakfast (during which the campers take turns in waiting on the table), bungalow or tent duties, inspection and assembly. The regular morning and afternoon activities include baseball, basketball, field events, tennis, riflery, archery, riding, dancing, swimming, canoeing, nature lore and craft work. In the evening there may be a camp fire, an entertainment by the glee or dramatic club, a council ring, or a "sing" on the lake. Taps usually sound about 8.30 or 9.00. There are the short, long and over-night hikes and canoe trips varying in extent from a few hours to a week or longer, the intercamp contests and jollifications, and the usually impressive Sunday services in the open. Nearly all camps publish a paper and conduct a store or "trading post." The fees range from about \$300 to \$450 for a period of nine weeks. The directors are frequently assisted by a staff of college trained men and women whose salaries vary from mere expenses to \$600 or more. There is nearly always a physician or trained nurse on the staff. The Camp Directors Association has drawn up a code of ethics to which its members are supposed to adhere; and the health departments of the various States exercise a fairly strict supervision over the sanitary appointments of the camps.

The social welfare and semi-public organizations were not slow in following the examples set by the private camp directors. Plainly if the sons and daughters of the well-to-do were profiting by their summers in the open air, it was even more important that these advantages be made available for the children of the moderately circumstanced: On favourable sites not too far removed from the more densely populated centres, there sprang up numerous inexpensive short-term camps that accept boys or girls usually in four or more shifts, each shift remaining for about two weeks. These camps are conducted by such organizations as the Y.M.C.A., the Y.W.C.A., the Boy Scouts of America, the Girl Scouts, Inc., the Campfire Girls, the Federation of Girls' Clubs, the Woodcraft League of America, Inc., the churches, Rotary and other service clubs, industrial and commercial enterprises, newspapers, magazines and many others. While no definite statistics are available, there are probably about 6,000 such camps in America with an annual population of approximately 1,000,000.

Finally, the municipal, county, State and national authorities began to take cognizance of this mass migration out into the open. Many cities have provided more or less permanent camps for their own residents and automobile camps for tourists. The county Governments are creating extensive park systems partly for camping purposes; the State Governments are blazing trails, setting aside areas for motor camping, constructing fire-places, erecting shelters, providing police and sanitary supervision; the Federal Government is developing millions of acres comprising the forest reserves and the national parks, building roads, establishing camp sites and leasing them out at a nominal rent to properly qualified individuals and organizations and issuing printed matter that deals with the various aspects of outdoor living. It is impossible to estimate the number of millions of people who every year avail themselves of these opportunities.

### HOW TO CAMP

A good camper may be likened to a good woodsman. He does not go with scanty outfit to endure as many hardships as he can stand—revelling in his stamina—but rather he makes the most of his equipment and the resources of nature and lives happily and comfortably in the woods. He goes camping to have a good time and returns to his work with increased health and vigour. This

is possible only when he is dressed comfortably, sleeps well at night and eats properly.

The tent is the camper's logical shelter—light and portable—cool in summer and warm in winter. It may range from a simple three-pound lean-to or shelter cloth capable of sheltering from wind and rain one or two campers in brief overnight camps, to large wall tents divided by canvas partitions that accommodate whole families of outdoor enthusiasts. The proper size and style depends upon the number camping, the nature of their trip and means of transportation.

The big game hunter who moves often and carries his outfit on his back prefers the light shelter cloth or a feather-weight silk tent just big enough to hold his sleeping bag. The shelter cloth is simply a waterproofed sheet 5 by 7 ft. for one and 8 by 12 ft. for two campers. Short pieces of tape are sewed on the long sides. These are tied to poles, one pole being staked to the ground and the other raised on forked stakes so the sheet stands at an angle of 45°. With the back upwind and a blazing fire at the front this simple device is quite comfortable in even cold weather.

The wall tent is a favourite for periods of one-spot camping. It can be supplied with a wooden floor and an extra fly that projects in front to form a shaded front porch. For short stays at one location, canoeists, fishermen and hunters use a large variety of quickly pitched tents like the tepee style, the miner's wedge tent and the Baker shelter tent. In the mountains of the Northwest the Indian tepee is a favourite. It requires a dozen poles at least 20 ft. long to erect properly and is only practical where straight young timber grows. In the territory named, however, it is so universally used that at nearly every good camp site stacks of poles are left by previous tenters. The tepee is the only tent in which an open fire will burn without smoking out the occupants and is one of the two remarkable inventions given us by the Indian.

Automobile campers, of whom there are 12,000,000 following the highway trails in America, use tents built especially for their purpose, usually square and pyramidal in shape with waterproof floors and a wide front door closed by an awning which is stretched out in front to form a sheltered porch. These are very practical and comfortable tents and are suitable for any style of camping where their weight of 50 to 70 lb. can be transported. The 7 by 9 ft. size is right for two campers and the 8 by 10 ft. size for four.

Tents should be absolutely waterproof or the camper will spend many hours in misery. Canvas fabric alone will not shed water unless pitched at an angle of at least 45°, and then it will leak readily when touched or rubbed from the inside. Make sure your tent has been treated with a waterproofing process. The green electric is best and will preserve the material for years. Such tents do not mould even if packed damp. In mosquito-infested country the tent should have a sewed-in waterproof floor and close-mesh bobbinet screens to cover door and window. For hot weather camping ventilation is very important and is best secured by a fair size window opposite the door. Tent makers insert windows at any point on order.

Tents must be pitched so the sides and roof are square and tight. Loose wrinkled canvas will not shed water and snow, and a drooping, sagging tent warps from shape and leaks at the seams. The guy ropes of unwaterproofed tents must be loosened in a rain or the canvas will pull the pegs when it starts shrinking. It is best to use steel tent pegs, for in some sections the ground is too hard for wood stakes to penetrate. If you camp on solid rock, and such camps are at times necessary in the upper Great Lakes region, cut four heavy poles, lash them in a square to fit the base of your tent and tie the bottom edges of it to them. To make guy ropes hold in loose sand, tie bundles of brush or sticks to the end and bury them a foot deep.

A good camp site has convenient supplies of water and firewood, shade in the late afternoon, protection from severe storms and wind and good drainage. The water-supply should carry an assurance of being reasonably pure. If in doubt boil it before drinking. Contrary to popular belief running water does not purify itself and a fast flowing stream may be badly polluted, especially when in a flood stage. Small springs issuing from rock

are usually safe. Sometimes subterranean springs are found near the edge of rivers and lakes which supply pure cold water. You can locate them with your hand trailing behind a boat. A sudden cold spot means a spring and then you dig ashore several feet back from the water's edge. Or a weighted canteen is lowered to the bottom with a string tied to the cork which is pulled when the vessel reaches the supply of fresh water. Impurities in running or still water are of animal origin and not vegetable. Rotting vegetation does not always mean impure water. Vinegar or lemon juice will neutralize the alkali water of semi-arid regions.

The summer camper requires only a small amount of fuel for camping but the cold weather camper needs considerable for keeping his tent warm and he should camp where good fuel is available. Dead standing timber makes the best firewood. If dry wood is unavailable remember that hickory burns the best of any green wood. Chestnut, beech, birch and mountain ash will all burn freely in a green state. Green pine and spruce are worthless.

In warm weather stand the tent so it is shaded from two to four o'clock in the afternoon—the hottest period of the day. In cold weather observe the directions of prevailing winds as shown by standing timber which bends away from the seasonal blow and camp with a windbreak of woods or rock at the rear. Keep away from thickets and dense woods. These places are damp and unwholesome and thronged with insect pests. The tent should stand on a gentle slope to carry off surface water in heavy rains. Aid this drainage by digging a 6 in. trench around the bottom of the tent. Never camp in a depression where water will gather and stand.

In camping along a river observe the high flood mark as shown by the bits of dead grass, leaves and mud along the brush on the water front and camp well above it. Avoid the deep dry washes of western States, for sudden rains will fill them dangerously full in a few minutes. Do not camp under trees with dead limbs. Rather camp in the open where your tent will dry quickly after rain or dew and there is no danger of falling trees.

The simplest and cheapest form of camp bed and one fairly satisfactory is a tick or bag of stout waterproof material 30 by 76 in. in size. The camper fills this at his camp site with dry material—leaves, dead grass or pine needles and pins the edge shut with safety pins. With two medium weight blankets this makes a comfortable summer bed. Canvas cots are standard camp furniture when their weight and bulk can be carried, but they are quite cold underneath and the sleeper should have at least twice as many blankets under him as on top. Paper blankets or even newspapers are good insulation for cots. Where light weight and the most comfort are desired there are two camp beds built on the pneumatic principle. These are the air mattress used with separate blankets and the sleeping bag or pocket which incorporates eiderdown quilting for warmth. The air mattress is made of rubber with an outside canvas cover and when properly inflated rivals the old-fashioned feather tick for comfort. When deflated it occupies a very small space and weighs but a few pounds. These beds are spread directly upon the tent floor. Camp blankets should be of light wool; two light blankets are better than one heavy one. Big game hunters usually prefer the sleeping bag which is a combination of air mattress and down quilts. They are the warmest beds in existence for their weight and bulk. The only drawback is their expense.

Camp cookery has undergone a substantial change in the past years. Formerly the camp cook's cuisine was limited to the standbys of bacon, beans and flapjacks and campers' stomachs were frequently upset with rich heavy foods. Now the experienced camp cook carries a wider variety of foods and handles his limited cooking equipment in a more effective manner. The light reflecting oven purchased at any outdoor goods store bakes biscuits, cakes and meats without the trouble of digging a bean hole or packing the sooty Dutch oven. The overworked frying pan is getting a much needed vacation. And dried milk, dried eggs and dehydrated vegetables prepared by adding water are nearly equal to the fresh products. The camper's grub bag should contain bacon, beans, cornmeal, oatmeal, rice, flour, baking powder, sweet chocolate, an assortment of dehydrated vegetables, dried

or condensed milk, sugar, lard, butter in hermetically sealed tins, dried or fresh eggs, dried fruits, salt, pepper, coffee or tea and a few tit-bits like jams, jellies and cheese. This sounds like an extensive list but the secret of successful camp provisioning is to carry small quantities of a large variety. For example, in place of 15 lb. of flour take three 5 lb. sacks of flour, oatmeal and cornmeal. Dry foods are packed in small 3 and 5 lb. waterproof bags sold by camp outfitters. These are stacked in a larger 50 lb. duffle bag. Bacon, butter and lard can be carried in friction top tins procurable from the same source. Do not carry flour in its regular sack. It will collect moisture and spoil. For short trips it is a good idea to mix the flour with salt and baking powder in the proper proportions for quick bread before starting. One can open the top of the sack, punch a hole down in the flour with his fist, pour in a cup of water and mix a ball of dough which is lifted directly into the oven or baking pan. This saves soiled utensils, and dish washing is a big bugaboo of camping. To clean a greasy frying pan boil up water and a handful of ashes from the camp fire in it. Knives are scoured by sticking them in sandy earth.

A man will eat slightly over 4 lb. of food per day or 29 lb. per week. Men living an outdoor life feel an increased craving for food rich in protein and sugar and this must be remembered when the supplies are chosen.

Campers usually find fish or small game to vary the menu. Fish are at their best when eaten fresh, but game improves by hanging one or two days to bleed and tender. It should be protected from flies by a sack of netting. Amateur cooks should remember that most varieties of game are strong with a characteristic odour and the taste is improved by parboiling.

The best camp utensils are aluminium. Regular cook kits may be purchased which nest together in a compact canvas bag and are very light. When the outfit is small the camper uses his ingenuity. A flat rock heated by building a fire on it makes an excellent baking stand. Brush off the coals and ashes, set the bread on the hot stone and invert a pan over it. Bread is baked, by timber cruisers who carry only a frying pan and small kettle, by twisting the thick dough about a green club of sweet wood which has been previously heated over the fire. It is then stood in the ground leaning to the heat and bakes delicious browned bread.

Every region has some material provided by nature for building quick fires. If the woods are wet birch bark always flares when touched by a match. Dead cedar roots in the West and rich pine knots in the South aid the camp fire builder. If none of these are handy, search for a dry squirrel nest in some hollow limb. To find dry fuel after a rain, cut into a tree that has died standing, or locate limbs on a fallen log which have not touched the ground. A short chunk of thick candle is fine to start damp wood and saves many matches. Candles also make good camp light and may be set in a tin can filled with earth.

The cooking fire should be small. Lay two 5 ft. logs close together and build the fire between them. Set your utensils on their tops. When gasoline can be obtained, the small gas stoves used by auto campers are the last word for camp cooking—clean and easy to control. Coals are better for cooking than a blaze. As a rule hardwoods burn to coals and softwoods burn to ashes. Always remember the fire hazard. Clear the ground of inflammable material—leaves and dry mould—before building the camp fire. Never leave a spark when you break camp. Soak the ashes with water or cover them with fresh earth.

Stout khaki is standard for summer camping-clothes. Cool weather calls for light-weight wool underwear as wool does not absorb perspiration and become clammy. The wool-dressed camper can strip after a wetting, wring out his garments, put them on again, walk briskly a half hour and feel dry with little risk of catching cold. A partly worn business suit is very comfortable for camping, but be sure the material is stout enough to stand the hard wear it will receive. Shoes should be well broken in before you leave for camp. Foot misery will spoil the vacation completely. A light raincoat and a wool sweater for cool evenings are necessary.

Every camper should take such few simple remedies as experience tells him might be necessary and a first-aid kit for wounds.

Red Cross outfits may be purchased ready assembled. Keep your camp site clean and sanitary. Enjoy nature but respect her domain and leave it unspoiled for the next camper to enjoy.

(M. H. DE.)

**CAMPION, EDMUND** (1540-1581), English Jesuit, was born in London and educated at Christ's hospital and St. John's college, Oxford. About 1564 religious difficulties began to beset him, but at the persuasion of Edward Cheyney, bishop of Gloucester, although holding Catholic doctrines, he took deacon's orders in the English Church. Inwardly "he took a remorse of conscience and detestation of mind," and in 1569 left Oxford to take part in a proposed restoration of Dublin university. Followed by suspicion, he at last escaped to Douai, where he joined William Allen (*q.v.*) and was reconciled to the Roman Church. After being ordained sub-deacon, he became a Jesuit at Rome in 1573. In 1580 the Jesuit mission to England was begun, and he accompanied Robert Parsons (*q.v.*) who, as superior, was intended to counter-balance Campion's impetuous zeal. In England he led a hunted life, preaching and ministering to Catholics in Berkshire, Oxfordshire, Northamptonshire and Lancashire. His *Decem Rationes* against the Anglican Church was privately printed and 400 copies were found on the benches of St. Mary's, Oxford, at the Commencement, on June 27, 1581. The sensation was immense, and the pursuit became keener. When preaching at Lyford, in Berkshire, on July 14 he was captured by a spy and taken to London, bearing on his hat a paper with the inscription, "Campion, the Seditious Jesuit." Committed to the Tower, he was examined in the presence of Elizabeth, who asked him if he acknowledged her as queen of England, and on his affirmative reply she made him offers of life, wealth and dignities on conditions which his conscience could not allow. He was kept a long time in prison, twice racked by order of the council, and every effort was made to shake his constancy. Despite the effect of a false rumour of retraction and a forged confession, his adversaries in despair summoned him to four public conferences (1st, 18th, 23rd and 27th of September), where his ease won the admiration of the audience. Racked again on Oct. 31, he was indicted at Westminster that he with others had conspired at Rome and Reims to dethrone the queen. On Nov. 20, when found guilty, he remarked: "If our religion do make traitors we are worthy to be condemned; but otherwise are and have been true subjects as ever the queen had." He received the sentence of the traitor's death with the *Te Deum laudamus*, and suffered the barbarous penalty on Dec. 1, 1581. Of all the Jesuit missionaries who suffered for their allegiance to the ancient religion Campion stands the highest. His life and his aspirations were pure, his zeal true and his loyalty unquestionable. He was beatified by Leo XIII. in 1886.

The last of the forty-seven editions of the *Decem Rationes* appeared with an Eng. trans. in vol. 6 of "The Catholic Library." See R. Simpson, *Edmund Campion* (1867); H. Foley, *Records of the English Province of the Society of Jesus* (1877).

**CAMPION, THOMAS** (1567-1620) English poet and musician, was born in London on Feb. 12, 1567, and christened at St. Andrew's, Holborn. He was the son of John Campion of the Middle Temple, who was by profession one of the cursitors of the chancery court, the clerks "of course," whose duties were to draft the various writs and legal instruments in correct form. His mother was Lucy Searle, daughter of Laurence Searle, one of the queen's sergeants-at-arms. Upon the death of Campion's father in 1576, his mother married Augustine Steward and died herself soon after. Steward sent him in 1581 to Peterhouse, Cambridge, as a gentleman pensioner. He left the university, it would appear, without a degree, but strongly imbued with those tastes for classical literature which exercised such powerful influence upon his subsequent work. In April 1586 he was admitted to Gray's Inn, but he does not appear to have been called to the bar. In 1591 he seems to have taken part in the French expedition under Essex, sent for the assistance of Henry IV. against the League; and in 1606 he first appears with the degree of doctor of physic. He practised as a physician until his death in London on March 1, 1620. A group of five anonymous poems by Campion was included in the *Songs of Divers Noblemen and Gentlemen*, appended

to Newman's surreptitious edition of Sidney's *Astrophel and Stella*, which appeared in 1591. In 1595 appeared under his own name the *Poemata*, a collection of Latin panegyrics, elegies and epigrams. This was followed in 1601 by *A Booke of Ayres*, the music of which was contributed in equal proportions by himself and Philip Rosseter, while the words were almost certainly all written by him. The following year he published his *Observations in the Art of English Poesie*, "against the vulgar and unartificial custom of riming," in favour of rhymeless verse on the model of classical quantitative poetry. The challenge thus thrown down was accepted by Daniel whose *Defence of Ryme* was published in the same year.

In 1607 he wrote and published a masque for the occasion of the marriage of Lord Hayes, and in 1613 he issued a volume of *Songs of Mourning* (set to music by Coperario or John Cooper) for the loss of Prince Henry. The same year he wrote and arranged three masques, the *Lords' Masque* for the marriage of Princess Elizabeth, an entertainment for the amusement of Queen Anne at Caversham House, and a third for the marriage of the earl of Somerset to Frances Howard, countess of Essex. If, moreover, as appears likely, his *Two Bookes of Ayres* (both words and music written by himself) belongs also to this year, it was indeed his *annus mirabilis*.

Some time in or after 1617 appeared his *Third and Fourth Booke of Ayres*; while to that year probably also belongs his *New Way of making Foure Parts in Counter-point*, a technical treatise which was for many years the standard text-book on the subject. It was included, with annotations by Christopher Sympson, in Playfair's *Brief Introduction to the Skill of Musick*, and two editions appear to have been bought up by 1660. In 1618 appeared *The Ayres that were sung and played at Brougham Castle* on the occasion of the king's entertainment there, the music by Mason and Earsden, while the words were almost certainly by Campion; and in 1619 he published his *Epigrammatum Libri II. Umbra Elegiarum liber unus*, a reprint of his 1595 collection with considerable omissions, additions (in the form of another book of epigrams) and corrections.

While Campion had attained a considerable reputation in his own day, in the years that followed his death his works were forgotten. The masque was practically extinguished by the Puritan revolution, which also, with its distaste for all secular music, put an end to the madrigal. Its loss involved that of many hundreds of dainty lyrics, including those of Campion, and it was only when Mr. A. H. Bullen published a collection of the poet's works in 1889, that his genius was again recognized.

Campion set little store by his English lyrics; they were to him "the superfluous blossoms of his deeper studies," but we may thank the fates that his precepts of rhymeless versification so little affected his practice. His rhymeless experiments are certainly better conceived than many others, but they lack the spontaneous grace and freshness of his other poetry. Not one of his songs is unmusical; moreover, the fact of his composing both words and music gave rise to a metrical fluidity which is one of his most characteristic features. Rarely indeed are his rhythms uniform, while they frequently shift from line to line. His range was very great both in feeling and expression, and whether he attempts an elaborate epithalamium or a simple country ditty, the result is always full of unstudied freshness and tuneful charm. In some of his sacred pieces he is particularly successful, combining real poetry with genuine religious fervour.

**BIBLIOGRAPHY.**—*Works*, etc. (1889), excluding *A New Way*, etc.; *Songs and Masques* (1903), with an introduction on Campion's music by Janet Dodge; *Poems*, etc. (1907); *Complete Works* (1908). The "Observations in the Art of English Poesie" are also published in Haslewood's *Ancient Critical Essays* and Gregory Smith's *Elizabethan Critical Essays*, vol. ii. (1903). (S. P. V.)

**CAMPISTRON, JEAN GALBERT DE** (1656–1723), French dramatist, was born at Toulouse of noble family. At the age of 17 he was wounded in a duel and sent to Paris, where he became an ardent disciple of Racine. In 1685 he scored his first success with *Andronic*, which disguised under other names the tragic story of Don Carlos and Elizabeth of France. Racine was asked by Louis Joseph, duc de Vendôme, to write the book of

an opera to be performed at a fête given in honour of the Dauphin. He handed on the commission to Campistron, who produced *Acis et Galathée* for Lulli's music. He wrote many tragedies and two comedies, one of which, *Le Jaloux désabusé*, has been considered by some judges to be his best work. In 1686 he had been made intendant to the duc de Vendôme and followed him to Italy and Spain, accompanying him on all his campaigns. If he was not a good poet he was an honest man under circumstances in which corruption was easy and usual. Many honours were conferred on him, and in 1701 he was received into the Academy.

**CAMPOAMOR Y CAMPOSORIO, RAMON DE** (1819–1901), Spanish poet, born at Navia (Asturias). Abandoning his first intention of entering the Jesuit order, he studied medicine at Madrid, found an opening in politics as a supporter of the Moderate party, and became governor of Castellón de la Plana, of Alicante and of Valencia. His conservative tendencies grew more pronounced with time, and his *Polémicas con la Democracia* (1862) may be taken as the definitive expression of his political opinions. His first appearance as a poet dated from 1840, when he published his *Ternesas y flores*, a collection of idyllic verses, remarkable for their technical excellence. These were followed by *Ayes del Alma* (1842) and *Fábulas morales y políticas* (1842). Campoamor's theatrical pieces, such as *El Palacio de la Verdad* (1871), *Dies Irae* (1873), *El Honor* (1874) and *Glorias Humanas* (1885), are interesting experiments; but they are totally lacking in dramatic spirit. He always showed a keen interest in metaphysical and philosophic questions, and defined his position in *La Filosofía de las leyes* (1846), *El Personalismo* (1855), *Lo Absoluto* (1865) and *El Ideismo* (1883). These studies are chiefly valuable as embodying fragments of self-revelation, and as having led to the composition of those *doloras*, *humoradas* and *pequeños poemas*, which the poet's admirers regard as a new poetic species. The first collection of *Doloras*, philosophic epigrams, was printed in 1846, and it cannot be denied that the poet's special gifts of irony, grace and pathos find their best expression in them. Taking a commonplace theme, he presents in four, eight or twelve lines a perfect miniature of condensed emotion, and by his choice of a vehicle he has avoided the fatal facility and copiousness which have led many Spanish poets to destruction. But his influence has not been always for good. His formula is too easily mastered, and to his example is due a plague of *doloras* and *humoradas* by poetasters who have caricatured their model. Though the title of a philosophic poet will be denied to him, he will survive, at least in extract, as a distinguished humorist, an expert in epigrammatic and sententious aphorism, and an artist of extremely finished execution. (J. F.-K.)

**CAMPOBASSO**, a city of Molise (see ABRUZZI E MOLISE), Italy, the capital of the province of Campobasso, 172m. E.S.E. of Rome by rail, situated 2,132ft. above sea-level. Pop. (1921) town 12,118; commune 16,330. The town itself has some fine modern edifices and a museum of Samnite antiquities. Its chief industry is the manufacture of arms and cutlery. Above the town are the picturesque ruins of a castle of 1458. The town, with the territory surrounding it, was under the feudal rule of counts until 1739.

**CAMPODEA**, a small whitish, wingless insect of the order Thysanura, sub-class Apterygota (*q.v.*) with long flexible antennae, and a pair of elongated caudal filaments. The best known species (*Campodea staphylinus*) is widely distributed in Europe and North America where it occurs under stones and logs, or in rotting leaves and soil.

**CAMPOMANES, PEDRO RODRÍGUEZ**, CONDE DE (1723–1802), Spanish statesman and writer, was born at Santa Eulalia de Sorribia, Asturias. From 1788 to 1793 he was president of the council of Castile; but on the accession of Charles IV. he retired from public life, regretted by the true friends of his country. During his tenure of office he had sought to reform taxation, to promote industry and trade, and to improve education. His principal works are two admirable essays, *Discurso sobre el fomento de la industria popular*, 1774, and *Discurso sobre la educación popular de los artesanos y su fomento*, 1775.

See the notice by A. Rodríguez Villa prefixed to the first edition of his *Cartas político-económicas* (1878).

**CAMPOS, ARSENIO MARTÍNEZ DE** (1831-1900), Spanish marshal, senator and knight of the Golden Fleece, was born at Segovia. He took part in the Morocco campaign of 1859-60, and in the expedition to Mexico under Prim. In 1869 he was sent to Cuba, where he was promoted to the rank of general in 1872. On his return to Spain he distinguished himself against the Cantonal Republicans and the Carlists. About that time he began to conspire with a view to restore the son of Queen Isabella. He joined Gen. Daban at Sagunto on Dec. 29, 1874, where he proclaimed Alphonso XII. king of Spain. From that date he was considered as a sort of supreme counsellor, being consulted by King Alphonso, and later by his widow, the queen-regent, in every important political crisis, and on every international or colonial question, especially when other generals or the army itself became troublesome. He took an important part in the military operations against the Carlists, and in the negotiations with their leaders, which put an end to the civil war in 1876. In the same way he pacified Cuba in 1878. On his return he was prime minister for a few months, but soon made way for Canovas. In 1881, with other discontented generals, he assisted Sagasta in obtaining office. After the death of King Alphonso, Campos steadily supported the regency of Queen Christina. In 1893 he commanded the Spanish army at Melilla, and negotiated with the court of Morocco, a treaty which averted a war. He was sent out by the Conservative cabinet of Canovas to cope with the rebellion in Cuba in 1895, but he failed in the field, as well as in his efforts to win over the Creoles. After the war with America, and the loss of the colonies in 1899, when Señor Silvela formed a new Conservative party and cabinet, the old marshal accepted the presidency of the Senate, though his health was failing fast. He died at Zarauz, a village on the coast of Guipuzcoa.

**CAMPOS**, an inland city of the State of Rio de Janeiro, Brazil, on the Parahyba river, 30 m. from the sea, and about 143 m. N.E. of the city of Rio de Janeiro. In 1926 the population of the city was 48,108. The river is navigable for small steamers above and below the city, but is closed to coast-wise navigation by dangerous sandbars at its mouth. The shipping port for Campos is Imbetiba (near Macahé), 60 m. south-west, with which it is connected by rail. There is also water communication between the two places by means of coastal lakes united by canals. The elevation of the city is only 69 ft. above sea-level, and it stands near the western margin of a highly fertile alluvial plain devoted to the production of sugar. The climate is hot and humid, and many kinds of tropical fruit are produced in abundance.

**CÂMPULUNG**, the capital of the department of Muscel, Rumania, and seat of a suffragan bishop; situated among the outlying hills of the Carpathian mountains on the river Tîrgului, a tributary of the Argeş. Pop. (1924), 18,500. Câmpulung is a popular summer resort. The Tîrgului supplies water-power for several paper-mills; annual fairs are held on July 20 and Oct. 20; and there is a considerable traffic with Transylvania and with the south by a branch railway to Ploesti. A German colony was established at Câmpulung in the 12th century but could not be maintained. Afterwards it was for a short time the first capital of Wallachia. The monastery and cathedral claim to have been founded by the Voivode Radul Negru in the 13th century.

**CAMPUS**, a Latin word meaning level plain. By the Romans the name was given to a number of open grassy spaces in and about the city. Of these the most famous was the Campus Martius on the north-west which became the property of the State after the expulsion of the Tarquins. It was the site of the comitia curiata, of the horse-races in honour of Mars, of athletic and military events, a place of reception for foreign ambassadors and a recreational centre.

American colleges, fond of classic terminology and richer in land than they were in buildings, early used the word campus to describe their grounds. Although yard is the term in vogue at Harvard and although yard and green long dominated at Yale, in common usage campus has prevailed over all others as a term

describing the land owned by a college or university and used for its purposes. A large and often beautiful campus forms frequently the most attractive feature of many American colleges and has become the centre of college traditions and the site of many distinctive customs. The connotations of the term gradually widened until in the second decade of the 20th century it tended to become synonymous for the non-scholastic life of an American college and descriptive of the athletic, social, dramatic and other extra-curricular activities. A man is spoken of, for instance, as a "campus leader"; "campus politics" form a training school for many a budding legislator; "campus activities" are those not concerned with books or study.

See Albert Matthews, "The Use at American Colleges of the Word Campus" (*Mass. Hist. Soc. Pub.*, vol. 3) and the *Nation* (vol. 66, 1898).

**CAMUCCINI, VINCENZO** (1773-1844), Italian historical painter, was born at Rome. He was educated by his brother Pietro, a picture-restorer, and Borubelli, an engraver. Camuccini belonged to the school of the French artist David. His works are rather the fruits of great cleverness and patient care than of fresh and original genius. He was appointed director of the Academy of San Luca and of the Neapolitan Academy at Rome, and conservator of the pictures of the Vatican. His chief works are the classical paintings of the "Assassination of Caesar," the "Death of Virginia," the "Devotion of the Roman Women," "Young Romulus and Remus," "Horatius Coclès," the "St. Thomas," which was copied in mosaic for St. Peter's, the "Presentation of Christ in the Temple," and a number of excellent portraits.

**CAMULODUNUM**, a British and Roman town, the modern Colchester (*q.v.*). It was the capital of the British chief Cunobelin and is named on his coins; after his death and the Roman conquest of south Britain, the Romans established (about A.D. 48) a *colonia* or municipality peopled with discharged legionaries, and intended to serve both as an informal garrison and as a centre of Roman civilization. It was stormed and burnt A.D. 61 in the rising of Boadicea (*q.v.*), but soon recovered and became one of the chief towns in Roman Britain. The town is named after Camulos, the Celtic Mars.

**CAMUS, ARMAND GASTON** (1740-1804), French revolutionist, was born in Paris. In 1789 he was elected by the third estate of Paris to the States General, and attracted attention by his speeches against social inequalities. Camus was a Jansenist, and a member of the ecclesiastical committee which presented the Civil Constitution of the Clergy to the Assembly in May 1790. Elected to the National Convention by the department of Haute-Loire, he was named member of the committee of general safety, and then sent as one of the commissioners charged with the surveillance of General C. F. Dumouriez. Delivered with his colleagues to the Austrians on April 3, 1793, he was exchanged for the daughter of Louis XVI. in Nov. 1795. He played an inconspicuous rôle in the Council of the Five Hundred. On Aug. 14, 1789, the Constituent Assembly made Camus its archivist, and in that capacity he organized the national archives, classified the papers of the different assemblies of the Revolution and drew up analytical tables of the *procès verbaux*. He was restored to the office in 1796. He remained an austere republican, refusing to take part in the Napoleonic régime. His principal work is *Code judiciaire, ou Recueil des décrets de l'Assemblée nationale et constituant sur l'ordre judiciaire* (1792).

**CAMUS DE MEZIERES, NICOLAS LE** (1721-1789), French architect, was born at Paris on March 26, 1721, and died there on July 27, 1789. He published several works on architectural and related subjects, including *Dissertation . . . en réponse au Mémoire de M. Paris du Verney, sur la Théorie et la Pratique des grès bois de charpente* (in collaboration with A. Babuty Desgodetz, 1763), and *Traité de la force des bois* (1782).

**CANA**, of Galilee, the scene of Christ's first miracle (John ii.), and an act of healing (John iv.); also the home of Nathanael (John xxi. 2). The evidence favours identification with *Kefr Kenna* about 4 m. N.N.E. of Nazareth on the road to Tiberias; pop. 1,175 (682 Moslems). There are Latin and Greek churches, the former occupying the site of an ancient basilica claimed to

be of the age of Constantine. Mosaic paving with an early Hebrew inscription has been discovered below its floor. The alternative identification, *Khirbet Kānā*, is a ruined site 9 m. N. of Nazareth with rock-cut tombs and cisterns but possessing no spring.

**CANAAN, CANAANITES.** Canaan is, in the view of the biblical writers the "Promised Land" which God had allotted to Abraham and his seed (Gen. xii. 7; xiii. 15, etc.); the holy land of the representatives of the three great monotheistic religions. This hilly country, poor for purposes of cultivation, seemed to the Israelites coming out of the wilderness, to be a land "flowing with milk and honey" (Exod. iii. 8; Deut. xi. 9, *sqq.*, etc.). If grape-honey is to be understood, this term is connected with two chief activities of the country, cattle breeding and wine-growing. But the mythological explanation is more likely: Canaan is as a Paradise, and "milk and honey" then means something similar to "Nectar and Ambrosia" (*cf.* Deut. xxxii. 13 *sqq.*, also Is. vii. 15). Actually, in view of the conquered but still feared former inhabitants, Canaan signifies for the Israelites the temptation to fall back into Nature-worship (*cf.* Ezek. xvi. 29; xvii. 4; Ps. cvi. 38, and Gen. ix. 25).

**The Land.**—Canaan in spite of its small area, is of remarkable variety in geographical and climatic character. Natural conditions necessitated its cleavage, both politically and otherwise, into more or less independent cities and peoples. As a "hinterland," of the Phoenician ports especially, west Jordan was always receptive of foreign influences, but although, without any marked cultural stamp, it was (especially in the South) capable of independent development. Comparatively seldom do we find Canaan as the name of a country in non-biblical writings. Nowhere, as far as yet known, is the name older than the time of the Egyptian New Kingdom (*i.e.*, after 1600 B.C.). In the Hittite cuneiform texts from Boghaz-keui, we find Canaan (Kinahḫe, the same form in the Amarna texts), in a record concerning Mitanni and several (non-Semitic) north Syrian kingdoms (Kinza, Dunip, Ugarit, Kaṭna, etc.). Probably the name originally denoted the plains on the coast, including the Phoenician commercial cities, the lowlands and plains of the interior (*cf.* Num. xiii. 29), and eventually the whole of west Jordan. The etymology is unknown: the meaning "Lowland" must be rejected. In the Egyptian inscriptions (after Seti I., about 1300 B.C.) we find the name invariably with the definite article, "the Canaan."

**The Inhabitants.**—The Canaanites are often mentioned in the Old Testament, as one of the peoples of the country, by the side of Hittites, Amorites, Perezites, Hivvites and Jebusites (*e.g.*, Exod. iii. 8; Deut. vii. 1). Behind this enumeration lurks a true recollection of racial blending in pre-Israelite times. In the "table of nations," Gen. x. 6, *sqq.*, Canaan does not appear with the Semites, but as a son of Ham (*cf.* ix. 18 *sqq.*). This may be attributed to the fact that geographical and ethnical considerations have been crossed by ethico-religious ones: with Ham were classified (in addition to the despised negroes), all those who were inimical and dangerous to the chosen people. It may be that there is historical ground for this belief. Palestine must have been settled by a people from the north about 1600 B.C.; with this people were mixed the Mitanni and Harri, and all were under the dominion of an Aryan population. We find in Amarna times (*see* below) Indo-Aryan names among the rulers of Canaan. It is possible, though not demonstrable, that the Canaanites were connected with these conquerors who may be historically regarded as the forerunners of the Philistines. Thus, the two commonly-used names of the Holy Land, Canaan and Palestine (*i.e.*, "land of Philistines"), originate with non-Semitic peoples who were merely temporary rulers there (*see* PHILISTINES).

**Archaeology.**—When the Israelites entered Canaan (probably in two divisions, 1400 and 1200 B.C.), the civilization, as far as it had been influenced by Egypt and Babylon, was already in decay. The invasion of the Israelites does not fall at the dawn of history, but in the dusk of a stormy evening. About 1200 B.C. the aspect changed. The peoples of youthful Europe overran Asia Minor and Syria, and even menaced Egypt. Out of the Syro-Arabian desert came a young people of Semitic stock, the Aramaeans. Israel stood on the border between two ages. The religion of

Sinai and the culture of Canaan were the two conflicting factors in its history. The culture of Canaan, however, is itself a complicated structure, the fruit of a long history.

In the Old Testament we find little about this; the biblical authors paid more attention to the ways of God with His chosen people than to the hated and accursed aborigines. Excavation, on the other hand comes to our aid. As early as 1865 the "Palestine Excavation Fund" had been founded, and subsequently noteworthy preliminary work in Jerusalem was done. Systematical excavations in the Holy Land began in 1890 with the uncovering of Tell el-Hesi Lachish (or preferably Eglon). Since Palestine became mandated territory, a friendly rivalry has existed between the nations. Archaeological methods have been improved, the courses of old city walls have been followed, and the ruins within are uncovered layer by layer. So we gain an impression of this culture from the latest to the earliest stratum. The vessels and potsherds serve as a norm for the chronology. Excavations, such as those of Gezer, Megiddo, Beth Shan, Shechem, Gibeon (or Mizpah?) and Kirjath-Sepher, supply much interesting material. But ancient Canaan is a "dumb" country: there are no inscriptions. This is due to the perishable nature of their writing material. Papyrus, wood and leather disappeared in the wet soil. Some few pieces of clay tablets in cuneiform script have been found at Taanach and most recently at Shechem; but from these it would seem that the Canaanites wrote in this more permanent form only during the period 1400–1200 B.C. But history-writing is impossible without written records. Therefore the basis of the following historical sketch must be the references to Canaan in Egyptian, Babylonian and (cuneiform) Hittite sources, and above all (for the period 1400–1350 B.C.) the very important Canaanite cuneiform records found at el-Amarna in Egypt (*see* below).

**The Oldest Period** (Up to 2500 B.C.).—Human settlements and culture go back as far as the beginning of the history of mankind. In caves near Tabgha—north of the sea of Genesareth—was found a fragment of a skull of Neanderthal type (*Homo primigenius*). Traces of early Palaeolithic flint-implements were found at Balata (Shechem) and elsewhere, as also in the extreme south of the country at Ain Kuseime (in the region of the biblical Kadesh-Barnea). Surprisingly enough we find at different places (at Jerusalem, Askalon, Gaza) a mixture of implements and weapons of the earliest and later types; this can only be explained by the mixture of different racial elements. All this, however, is of so remote an age as to be beyond our reach. Not until about 3000 B.C. does the dawn of history begin. The majority of the megalithic monuments (barrows, cromlechs, dolmens, etc.) must be synchronous with the Old Kingdom of Egypt, as also must the oldest city-foundations. The fact that the Old Testament (*e.g.*, Num. xiii. 32 *sqq.*, Amos ii. 9) describes the aborigines as giants may be ascribed to these monuments. Only giants, it was imagined, could have raised these huge boulders. But the skeletal remains of the first layer of Gezer definitely belong to a small race, smaller than the Semites, who differed from the Semites by their use of cremation.

The immigration of the Semites (from the south and southwest) must have taken place before 3000 B.C. These oldest Semitic peoples of Canaan must have been (in speech also) closely akin to the oldest Semitic dwellers in north Babylonia (the Akkadians). From this source also came the Canaanites' knowledge of metals (copper and bronze), of vegetables, domestic animals and many other cultural and spiritual acquisitions which had been much earlier developed and improved by the Sumerians in Mesopotamia and the Egyptians of the Old Kingdom. Egyptian influence was stronger in Byblos, the ancient trading port of Lebanon's export of cedar-wood. Copper came from the mines at Wadi Maghara of Sinai. Thus culture developed rapidly in the territory between these two areas.

**The Old Canaanite Period** (First Bronze Age, 2600–2000 B.C.).—In the tomb of Inti (Deshasheh, Upper Egypt), we find the first representations of the conquest of Canaanite cities by Egyptians. Neither in arms nor in clothes were the Canaanites much inferior to the victorious Egyptians. About 100 years later (6th dynasty; according to the shortest reckoning, 2450 B.C.),

the Egyptian Uni, recorded in his tomb his victorious campaigns against the "sand-dwellers," who occupied the country of Canaan. The inscription recounts a struggle against sturdy nomads, who invaded Canaan, so keenly coveted by the Egyptians. Only after the intervention of the Egyptian fleet was the decisive battle fought, probably near the promontory of Carmel (in the plain of Megiddo). It may be supposed that these struggles are connected with the advance of the Amorites (*q.v.*) from their original territory on the middle course of the Euphrates. These invasions did not mean, however, much retrogression in civilization. The Amorites had a great capacity for adaptation and wherever they came, they spread the Mesopotamian culture, which they had themselves absorbed. Subsequently, they too were subjugated. Sargon I. of Akkad seized the "upper land," that is, as far as the Amanus and Taurus (?). Soon, however, the Amorites pressed forward to the coveted cultivated lands near the mouth of the great rivers: Euphrates, Tigris and the Nile. Of this first intermediate period (between the Old and Middle kingdom) we have little information concerning Egypt (*cf.* H. Frankfort, *Journal of Egypt. Archaeol.* vol. xii. 1926, pp. 80-99).

The classical period of the Middle kingdom shows a national Egyptian reaction against the Canaanite (Amorite) influence. We obtain an invaluable glimpse of the condition of Canaan at this time (*c.* 2000 B.C.) in the (romantic) story of Sinuhe, an Egyptian fugitive of high rank, who describes his experiences and exploits in Upper Retenu (*i.e.*, the mountains of Canaan). We gain the impression of well-regulated conditions, although without any central government. Mention is indeed made of the Egyptian claims, but the Canaanite chiefs did not concern themselves much about these. The peaceful relations between the two lands were of much greater importance.

**The Middle Canaanite Period** (Second Bronze Age, 2000 to 1600 B.C.).—The above-mentioned "kingdom of Retenu" was then (according to the hypothesis of A. Alt) an independent territory, with the later Lod-Lyddā, west of Jerusalem, as its capital; according to another view, the name is preserved in that of Lot or Lotan (*Camb. Anc. Hist.* i. 235). Independent of it was, probably, the "land of Shechem" in the heart of the mountains of Samaria, which was conquered about 1850 B.C. by Sesostri III. It is probable that the country then already consisted of several political territories, with scattered township centres. Unfortunately, thenceforth no written information exists for nearly 300 years; and this is all the more to be regretted as it is just these centuries—as excavations show—which formed the first great period in the culture of this country. The Hyksos stand out as a new power which ruled over Egypt and the surrounding lands. The ground-stock of its population must have been Amorite; the heads of the ruling classes were probably already Indo-Iranian. For the first time, Syria and Canaan formed the centre of a mighty kingdom which stretched, in all probability, over a part of Asia Minor and the Aegean islands.

Using strategic methods hitherto unknown—the introduction of horses and chariots—these knightly warriors conquered a great part of the world then known, and a feudal nobility shared the sovereignty over the conquered peoples. This explains how, even after the fall of the great kingdom, there existed in Canaan an aristocracy composed of many varied elements—Semitic, Indo-Aryan and Hittite. Their leaders (just as they did in Homeric Greece) claimed the title of "king." Everywhere in the country there arose circular or square fortresses, with double walls of mud. This is the period in Canaan in which we may expect to find palaces and temples with colonnaded halls, while the terraced constructions discovered in 1926-27 at Shechem (Tell el-Balata) appear to belong to the next period.

**The Late Canaanite Period** (Third Bronze Age, 1600-1200 B.C.).—The Theban kings of the 17th and 18th dynasties regarded themselves as the heirs to the Hyksos kingdom in Asia. For three years the conqueror of the Hyksos, Ahmose (Amosis) besieged the town of Sharuhēn (present Tell el-Khuff). With the fall of this fortress, South Palestine was at the mercy of the Egyptian conquerors, but the work was completed by Thutmose III. (1555-1501 B.C.). In 16 campaigns, culminating in the capture of Meg-

iddo (Tell el-Mutesellim), the key position of north Canaan, and Kadesh on the Orontes (Tell Nebi Mendi), the capital of the Amorites, Canaan was completely subjected to Egypt. In this "New Kingdom" Egypt was the dominant power, but Asiatic influences were then progressing in Egypt with more vigour than Egyptian influences in Asia. Probably in the period of Amenhotep III., "the Magnificent," Canaan was also covered with palaces and temples. The foundations of these have recently been discovered in Beth-Shan, and, perhaps, in Shechem. The "kings of Canaan" became the loyal servants of Pharaoh. In the north, however, the Hittite empire became a dangerous rival of Egypt.

The diplomatic language in which the rulers of Canaan communicated with the Egyptian sovereign and officials, and even occasionally among themselves, was still Babylonian. The discovery of the Tell el-Amarna tablets came as a flash-light in the obscurity of the history and culture of Canaan in the first half of the 14th century B.C. These tablets, which were found in 1889 on the site of the residence of the "heretic" king, Amenhotep IV. (Akhnaton), are in the Babylonian language and written in cuneiform, on clay. The reign of this philosopher on the throne of the Pharaohs was for Canaan a time of internal and external troubles. Egyptian supremacy (which, in the Old Testament, is not even mentioned) was approaching its end. However, the great Pharaohs of the 19th dynasty once again tightened the loosened bonds. Hor-em-heb received (even at the time of his ascending the throne) an oath of allegiance from the Asiatics. Seti I. and Ramses II. erected their steles of victory at Beth-Shan. The first made a treaty of peace with the Hittite king, Mutallish, which secured the possession of Canaan once again to the Egyptians. The latter made a similar treaty with Khattushilish III., but this was less favourable to the Egyptians, as he himself had with difficulty escaped defeat at the battle of Kadesh on the Orontes (autumn, 1288 B.C.). From the 12th century B.C. onwards, Egyptian claims to Canaan were brought to an end by the new immigrations from both sides: the Israelites and, subsequently, the Philistines.

**Israel.**—The problem of the exodus of the Israelites from Egypt and their entry into Canaan is chronologically one of the most difficult, and agreement on this point has not yet been reached. Many scholars identify the Children of Israel with the "Khabiri," the people who invaded Canaan in the Amarna Age. It was against these people that rulers of Canaan vainly appealed to the Pharaoh. This identification is the more convincing as the word "Khabiri" may, philologically, be identified with the word for "Hebrew" (*Yibri*). Moreover, Pharaoh Merneptah mentions, only 150 years later (*c.* 1220), the people of Israel in conjunction with the peoples and cities of Canaan. Other difficulties, however, stand in the way of this identification.

Probably, two invasions of Hebrew tribes must be distinguished (Burney, Sellin and others). A considerable movement of tribes is described in the patriarchal narratives in Genesis xxxi.-xxxv. in the form of more or less idyllic family history. The older Hebrew group, with which may be reckoned Edom, Moab and Ammon, and, above all, the Leah-tribes with Jacob as representative, may be identified with the "Khabiri" of the Amarna letters, and the Leah-tribes, in particular, with the "Israel" of Merneptah. The invasion of the younger group, on the other hand (the Rachel-tribes, Ephraim, Manasseh and Benjamin), which attacked Canaan with fire and sword under Joshua, in league with the older tribes, cannot be placed before 1200 B.C. Archaeological research confirms this view; from the strata of ashes and other indications of the excavations it appears (according to W. F. Albright), that Canaan in the third Bronze age, that is, during the period 1600-1200 B.C., suffered two conquests: the second of which was more violent and complete, the first at the beginning and the second at the end of this period. For us the most important age in the long eventful history of the land of Canaan begins with the entry of the Israelites. (*See* JEWS; PALESTINE: History.)

Burney, *Israel's Settlement in Canaan* (*The Schweich Lectures*, 1917). (F. M. T. B.)

**CANACHUS**, a sculptor of Sicyon of the latter part of the 6th century B.C. He made two great statues of Apollo with a stag and a bow, one in bronze for the temple at Miletus, and one in cedar wood for Thebes. The former is represented on coins of Miletus.

**CANADA.** The Dominion of Canada comprises the northern half of the continent of North America and its adjacent islands, excepting Alaska, which belongs to the United States, and Newfoundland, which is a separate dominion of the British empire. The north-eastern coast of Labrador belongs to Newfoundland. Its boundary on the south is the parallel of latitude 49°, between the Pacific Ocean and Lake-of-the-Woods, then a chain of small lakes and rivers eastward to the mouth of Pigeon river on the north-west side of Lake Superior, and the Great Lakes with their connecting rivers to Cornwall, on the St. Lawrence. From this eastward to the state of Maine the boundary is an artificial line nearly corresponding to latitude 45°; then an irregular line partly determined by watersheds and rivers divides Canada from Maine, coming out on the Bay of Fundy. The western boundary is the Pacific on the south, an irregular line a few miles inland from the coast along the "pan handle" of Alaska to Mount St. Elias, and the meridian of 141° to the Arctic Ocean. For much additional information concerning Canada, see BRITISH EMPIRE.

### GEOGRAPHY AND GEOLOGY

**Physical Geography.**—In spite of these restrictions of its natural coast line on both the Atlantic and the Pacific, Canada is admirably provided with harbours on both oceans. The Gulf of St. Lawrence with its much indented shores and the coast of Nova Scotia and New Brunswick supply endless harbours, the northern ones closed by ice in the winter, but the southern ones open all the year round; and on the Pacific British Columbia is deeply fringed with islands and fjords with well-sheltered harbours everywhere, in strong contrast with the unbroken shore of the United States to the south. The long stretches of sheltered navigation from the Straits of Belle Isle north of Newfoundland to Quebec, and for 600 m. on the British Columbian coast, are of great advantage for the coasting trade. To the North Hudson Bay, an inland sea 850 m. long from north to south and 600 m. wide, with its outlet Hudson Strait, has long been navigated by trading ships and whalers, and may become an outlet for the wheat of western Canada, though closed by ice except for four months in the summer. Of the nine provinces of Canada only two have no coast line on salt water, Alberta and Saskatchewan. Ontario and Manitoba have a seaboard only on Hudson Bay, where Churchill Harbour on the west side may become an important grain port. What Ontario lacks in salt water navigation is, however, made up by the busy traffic of the Great Lakes.

More than half Canada's surface slopes gently inwards towards the shallow Hudson Bay, with higher margins to the south-east and south-west. In the main it is a broad trough, wider towards the north than towards the south and unsymmetrical, Hudson Bay occupying much of its north-eastern part, while to the west broad plains rise gradually to the foot-hills of the Rocky Mountains.

**Geology.**—The mountain structures originated in three great orogenic periods, the earliest in the Archaean, the second at the end of the Palaeozoic and the third at the end of the Mesozoic. The Archaean mountain chains, which enclosed the present region of Hudson Bay, are so ancient that they had already been worn down almost to a plain before the early Palaeozoic sediments were

laid down. This ruling geological and physical feature of the North American continent has been named the "Canadian Shield." Round it the Palaeozoic sands and clays, largely derived from its own waste, were deposited as nearly horizontal beds, in many places still almost undisturbed. Later the sediments lying to the south-east of this "protaxis," or nucleus of the continent, were pushed against its edge and raised into the Appalachian chain of mountains. The Mesozoic sediments were almost entirely laid down to the west and south-west of the protaxis, upon the flat-lying Palaeozoic rocks, and in the prairie region they are still almost horizontal; but in the Cordillera they have been thrust up into the series of mountain chains characterizing the Pacific coast region. The youngest of these mountain chains is naturally the highest, and the oldest one in most places no longer rises to heights deserving the name of mountains. Owing to this unsymmetric development of North America the main structural watershed is towards its western side, on the south coinciding with the Rocky Mountains proper, but to the northward falling back to ranges situated farther west in the same mountain region. The central area of Canada is drained towards Hudson Bay, but the two largest Canadian rivers have separate watersheds, the Mackenzie flowing north-west to the Arctic Ocean and the St. Lawrence north-east towards the Atlantic, the one to the south-west and the other to the south-east of the Archaean protaxis. While these ancient events shaped the topography in a broad way its final development took place during the glacial period, when the loose materials were scoured from some regions and spread out as boulder clay, or piled up as moraines in others; and the original water-ways were blocked in many places. The retreat of the ice left Canada much in its present condition and the region has a very youthful topography with innumerable lakes and waterfalls as evidence that the rivers have not long been at work.

**Lakes and Rivers.**—As a result of the geological causes just mentioned many parts of Canada are lavishly strewn with lakes of all sizes, from bodies of water hundreds of miles long and a thousand feet deep to ponds lost to sight in the forest. The largest and most thickly strewn lakes occur within five hundred or a thousand miles of Hudson Bay, and belong to the Archaean protaxis or project beyond its edges into the Palaeozoic sedimentary rocks which lean against it. The most famous are those of the St. Lawrence system, which form part of the southern boundary of Canada and are shared with the United States; but many others have the right to be called "Great Lakes" from their magnitude. There are nine others which have a length of more than 100 m., and 35 which are more than 50 m. long. Within the Archaean protaxis they are of the most varied shapes, since they represent merely portions of the irregular surface inundated by some morainic dam at the lowest point. They often contain islands, sometimes even thousands in number, as in Georgian Bay and Lake-of-the-Woods.

In the Cordilleran region on the other hand the lakes are long, narrow and deep, in reality sections of mountain valleys occupied by fresh water, just as the fjords of the adjoining coast are valleys occupied by the sea. The smaller lakes are often rimmed with marshes and are slowly filling up with vegetable matter, ultimately becoming peat bogs, the *muskegs* of the Indian. Most of Canada is so well watered that the lakes have outlets and are kept fresh, but there are a few small lakes in southern Saskatchewan, e.g., the Quill and Old Wives lakes, in regions arid enough to require no outlets. In such cases the waters are alkaline, and contain various salts in solution which are deposited as a white rim round the basin towards the end of the summer when the amount of water has been greatly reduced by evaporation. It is interesting to find maritime plants, such as the samphire, growing on their shores a thousand miles from the sea and more than a thousand feet above it. In many cases the lakes of Canada simply spill over at the lowest point from one basin into the next below, so that canoe navigation may be carried on for hundreds of miles, with here and there a waterfall or rapid requiring a portage.

The river systems are in many cases complex and tortuous, and very often the successive connecting links between the lakes receive different names, well illustrated by the St. Lawrence, which

may be said to begin as Nipigon river and to take the names St. Mary's, St. Clair, Detroit and Niagara, before finally flowing from Lake Ontario to the sea under its proper name. As these lakes are great reservoirs and settling basins, the rivers which empty them are unusually steady in level and contain clear water. The St. Lawrence varies only a few feet in the year and always has pellucid bluish-green water, while the Mississippi, whose tributaries begin only a short distance south of the Great Lakes, varies 40 ft. or more between high- and low-water and is loaded with mud. The St. Lawrence has provided the main artery of exploration and with its canals past rapids and between lakes serves as a great highway of trade between the interior of the continent and the seaports of Montreal and Quebec. It is probable that politically Canada would have followed the course of the States to the south but for the planting of a French colony with widely extended trading posts along the easily ascended channel of the St. Lawrence and the Great Lakes, so that this river was the ultimate bond of union between Canada and the empire.

North of the divide between the St. Lawrence system and Hudson Bay there are many large rivers converging on that inland sea, such as Whale river, Big river, East Main, Rupert and Nottaway rivers coming in from northern Quebec; Moose and Albany rivers with important tributaries from northern Ontario; and Severn, Nelson and Churchill rivers from the south-west. They are rapid and shallow, but the largest of them, Nelson river, drains the great Manitoban lakes, Winnipeg, Winnipegosis and Manitoba, which are frequented by steamers, and receive the waters of Lake-of-the-Woods, Lake Seul and many others emptying into Winnipeg river from Ontario; of Red river coming in from the United States to the south; and of the southern parts of the Rocky Mountains and the western prairie provinces drained by the great Saskatchewan river.

The northern part of Alberta and Saskatchewan and much of northern British Columbia are drained through the Athabasca and Peace rivers, first north-eastwards towards Athabasca Lake, then north through Slave river to Great Slave Lake, and finally north-west through Mackenzie river to the Arctic Ocean. If measured to the head of Peace river the Mackenzie has a length of more than 2,000 m., and it provides more than 1,000 m. of navigation for stern-wheel steamers, serving the northern fur-trading posts.

Second among the great north-western rivers is the Yukon, which begins its course about 18 m. from tide-water on an arm of the Pacific, 2,800 ft. above the sea and just within the Canadian border. It flows first to the north, then to the north-west, passing out of the Yukon territory into Alaska, and ending in Bering Sea, 2,000 m. from its head-waters. The rest of the rivers flowing into the Pacific pass through British Columbia and are much shorter. The Columbia is the largest, but after flowing north-west and then south for about 400 m., it passes into the United States. The Fraser, next in size but farther north, follows a similar course, entering the sea at Vancouver; while the Skeena and Stikine in northern British Columbia are much shorter and smaller, owing to the encroachments of Peace and Liard rivers, tributaries of the Nelson, on the Cordilleran territory. In most cases these rivers reach the coast through deep valleys or profound canyons, and the transcontinental railways find their way beside them, the Canadian Pacific following at first tributaries of the Columbia near its great bend, and afterwards Thompson river and the Fraser; while the Canadian National makes use of the valley of the Skeena and its tributaries.

The divide between the rivers flowing west and those flowing east and north is very sharp in the southern Rocky Mountains, but there are two lakes, the Committee's Punch Bowl and the Fortress Lake, right astride of it, sending their waters both east and west; and the melting snows of the Columbia ice-field drain in three directions into tributaries of the Columbia, the Saskatchewan and the Athabasca, so that they are distributed between the Pacific, the Atlantic (Hudson Bay) and the Arctic Oceans. The divide between the St. Lawrence and Hudson Bay in eastern Canada is flat and boggy instead of being a lofty range of mountains.

As most of the Canadian rivers have waterfalls on their courses,

they are of much importance as sources of power. The St. Lawrence system, for instance, generates many thousand horse-power at Sault Ste. Marie, Niagara and the Lachine rapids. All the larger cities of Canada make use of hydro-electric power, and many enterprises of the kind have been carried out in eastern Canada, especially in Quebec.

**The Archaean Protaxis.**—The broad geological and geographical relationships of the country have already been outlined, but the more important sub-divisions may now be taken up with more detail, and for that purpose five areas may be distinguished, much the largest being the Archaean protaxis, covering 1,825,000 square m. It includes Labrador and most of Quebec on the east, northern Ontario on the south; and the western boundary runs from Lake-of-the-Woods north-west to the Arctic Ocean near the mouth of Mackenzie river. The southern parts of the Arctic islands, especially Banksland, belong to it also. This vast area, shaped like a broad-limbed V or U, with Hudson Bay in the centre, is made up chiefly of Laurentian gneiss and granite; but scattered through it are important stretches of Keewatin, Timiskaming and Huronian rocks intricately folded as synclines in the gneiss. The Keewatin, Timiskaming and Huronian, consisting of greenstones, schists and more or less metamorphosed sedimentary rocks, are of special interest for their ore deposits, which include most of the important metals, particularly nickel, copper, silver and gold. The southern portion of the protaxis is opened up by railways, but the far greater northern part is known only along the lakes and rivers which are navigable by canoe. Though once consisting of great mountain ranges there are now no lofty elevations in the region except along the Atlantic border in Labrador, where summits of the Nachvak Mountains reach 5,500 ft. In other parts the surface is hilly, the harder rocks, rising as rounded knobs, or ridges, while the softer parts form valleys generally floored with lakes.

From the summit of any of the higher hills one sees that the region is really a somewhat dissected plain, for all the hills rise to about the same level with a uniform skyline at the horizon. The Archaean protaxis is sometimes spoken of as a plateau, but probably half of it falls below 1,000 ft. The lowland part extends from 100 to 500 m. round the shore of Hudson Bay, and reaches south-west to the edge of the Palaeozoic rocks on Lake Winnipeg. Outwards from the bay the level rises slowly to an average of about 1,500 ft., but seldom reaches 2,000 ft. except on the eastern and southern coasts of Labrador. In most parts the Laurentian hills are bare *roches moutonnées* scoured by the glaciers of the Ice age, but a broad band of clay land extends across northern Quebec and Ontario just north of the divide. The edges of the protaxis are in general its highest parts, and the rivers flowing outwards often have a descent of several hundred feet in a few miles towards the Great Lakes, the St. Lawrence or the Atlantic, and in some cases they have cut back deep gorges or canyons into the tableland. The waterfalls are utilized at many points to work up into wood pulp the forests of spruce which cover much of Labrador, Quebec and Ontario.

As one advances northward the timber grows smaller and includes fewer species of trees, and finally the timber line is reached near Churchill on the west coast of Hudson Bay and somewhat farther south on the Labrador side. Beyond this are the "barren grounds" on which herds of caribou (reindeer) and musk ox pasture, migrating from north to south according to the season. There are no permanent ice sheets known on the mainland of north-eastern Canada, but some of the larger islands to the north of Hudson Bay and Straits are partially covered with glaciers on their higher points. Unless there are mineral resources, the barren grounds can never support a white population and have little to tempt even the Indian or Eskimo, who visit it in summer to hunt the deer in their migrations.

**The Acadian Region.**—The "maritime provinces" of eastern Canada, including Nova Scotia, New Brunswick and Prince Edward Island, may be considered together; and to these provinces may be added, from a physical point of view, the analogous south-eastern part of Quebec—the entire area being designated the Acadian region. Taken as a whole, this eastern part of Canada, with a very irregular and extended coast-line on the Gulf of St. Law-

rence and the Atlantic, may be regarded as a northern continuation of the Appalachian mountain system that runs parallel to the Atlantic coast of the United States. The rocks underlying it have been subjected to successive foldings and crumplings by forces acting chiefly from the direction of the Atlantic Ocean, with alternating prolonged periods of waste and denudation. The main axis of disturbance and the highest remaining land runs through the south-eastern part of Quebec, forming the Notre Dame Mountains, and terminates in the Gaspé peninsula as the Shickshock Mountains, some of which rise above 4,000 ft.

The province of New Brunswick exhibits approximately parallel but subordinate ridges, with wide intervening areas of nearly flat Silurian and Carboniferous rocks. The peninsula of Nova Scotia, connected by a narrow neck with New Brunswick, is formed by still another system of parallel ridges, deeply fretted on all sides by bays and harbours. Valuable coal-fields occur in Cape Breton and other parts of the province. Gypsum is quarried on a large scale in both provinces. Asbestos is the principal mineral product of that part of Quebec included in the region now under consideration. Extensive tracts of good arable land exist in many parts of the Acadian region. Its surface was originally almost entirely wooded, and the products of the forest continue to hold a prominent place. Prince Edward Island, the smallest province of Canada, is low and undulating, based on Permo-Carboniferous and Triassic rocks affording a red and very fertile soil, much of which is under cultivation.

**The St. Lawrence Plain.**—As the St. Lawrence invited the earliest settlers to Canada and gave the easiest communication with the Old World, it is not surprising to find the wealthiest and most populous part of the country on its shores and near the Great Lakes to which it leads; and this early development was greatly helped by the flat and fertile plain which follows it inland for over 600 m. from the city of Quebec to Lake Huron. This affords the largest stretch of arable land in eastern Canada, including the southern parts of Ontario and Quebec with an area of some 38,000 sq. m. The whole region is underlain by nearly horizontal and undisturbed rocks of the Palaeozoic from the Devonian downward. Superimposed on these rocks are Pleistocene boulder clay, and clay and sand deposited in post-glacial lakes or an extension of the Gulf of St. Lawrence. Though petroleum and salt occur in the south-west peninsula of Ontario, metalliferous deposits are wanting, and the real wealth of this district lies in its soil and climate, which permit the growth of all the products of temperate regions. To the north the Laurentian plateau rises directly from the upper Great Lakes; so that the fertile lands of the east with their numerous cities and largely-developed manufactures were at one time cut off by a rocky and forest-covered Archaean region from the far more extensive farm lands of the west. The development of mines and the spread of settlement on the clay belt have now filled the gap between east and west.

**The Interior Continental Plain.**—Passing westward by rail from the forest-covered Archaean with its rugged granite hills, the flat prairie of Manitoba with its rich grasses and multitude of flowers comes as a very striking contrast, introducing the Interior Continental plain in its most typical development. This great plain runs north-westward between the border of the Archaean protaxis and the Rocky Mountains, including the southern parts of Manitoba and Saskatchewan and most of Alberta. At the international boundary in latitude 49° it is 800 m. wide, but in latitude 56° it has narrowed to 400 m. in width, and to the north of latitude 62° it is still narrower and somewhat interrupted, but preserves its main physical features to the Arctic Ocean about the mouth of the Mackenzie. Most of the plains are underlain by Cretaceous and early Tertiary shales and sandstones lying nearly unaltered and undisturbed although now raised far above sea-level, particularly along the border of the Rocky Mountains where they were thrust up into foot-hills when the range itself was raised. Coal and lignite are the principal economic minerals met with in this central plain, though natural gas occurs and is greatly used, and there are important oilwells in the southern foothill region. Its chief value lies in its vast tracts of fertile soil suitable for growing wheat. The very flat and rich prairie near Winnipeg is

the former bed of the glacial Lake Agassiz; but most of the prairie to the west is of a gently rolling character and there are two rather abrupt breaks in the plain, the most westerly one receiving the name of the Missouri Coteau. The first step represents a rise to 1,600 ft., and the second to 3,000 ft. on an average. In so flat a country elevation of a few hundred feet is remarkable and is called a mountain, so that Manitoba has its Duck and Riding mountains. The treeless part of the plains, the prairie proper, has a triangular shape with an area twice as large as that of Great Britain. North of the Saskatchewan river groves of trees begin, and somewhat farther north the plains are generally wooded, because of the slightly more humid climate. It has been proved, however, that trees if protected will grow well on the prairie, as may be seen around the older farmsteads.

**The Cordilleran Belt.**—The Rocky Mountain region as a whole, best named the Cordillera or Cordilleran belt, includes several parallel ranges of mountains of different structures and ages, the eastern one constituting the Rocky Mountains proper. The Cordillera is 400 m. wide and covers towards the south almost all of British Columbia and a strip of Alberta east of the watershed, and towards the north forms the whole of the Yukon Territory. Two principal mountain axes form its ruling features—the Rocky Mountains proper, above referred to, and the Coast Ranges. Between them are many other ranges shorter and less regular in trend, such as the Selkirk Mountains, the Gold Ranges, and the Cariboo Mountains. There is also in the southern inland region an interior plateau, once probably a peneplain, but now elevated and greatly dissected by river valleys, which extends north-westward for 500 m. with a width of about 100 m. and affords the largest areas of arable and pasture land in British Columbia. Similar wide tracts of less broken country occur in northern British Columbia and to some extent in the Yukon Territory, where wide valleys and rolling hills alternate with short mountain ranges of no great altitude. The Pacific border of the coast range of British Columbia is ragged with fjords and channels, where large steamers may go 50 or 100 m. inland between mountain walls as on the coast of Norway; and there is also a bordering mountain system partly submerged forming Vancouver Island and the Queen Charlotte Islands.

The highest mountains of the Cordillera in Canada are near the southern end of the boundary separating Alaska from the Yukon Territory, the meridian of 141° and they include Mount Logan (19,850 ft.) and Mount St. Elias (18,000 ft.), while the highest peak in North America, Mount McKinley (20,000 ft.) is not far to the north-west in Alaska. Near the height of land between British Columbia and Alberta there are many peaks which rise from 10,000 to 12,000 ft. above sea-level, the highest being Mount Robson (12,972 ft.). The next range to the east, the Selkirks, has summits that reach 11,000 ft. or over, while the Coast Ranges sometimes reach 13,000 ft. The snow line in the south is from 7,500 to 9,000 ft. above sea-level, being lower on the Pacific side where the heaviest snowfall comes in winter than on the drier north-eastern side. It gradually sinks as one advances north-west, reaching only 3,000 ft. on the Alaskan coast. The Rockies and Selkirks support hundreds of glaciers, mostly not very large, but some having 100 sq.m. of snowfield.

All the glaciers are now in retreat, with old tree-covered moraines, hundreds or thousands of feet lower down the valley. The timber line is at about 7,500 ft. in southern British Columbia and 4,000 ft. in the interior of the Yukon Territory. On the westward slopes, especially of the Selkirks and Coast Ranges, vegetation is almost tropical in its density and luxuriance, the giant cedar and the Douglas fir sometimes having diameters of 10 ft. or more and rising to the height of 250 ft. On the eastern flanks of the ranges the forest is much thinner, and on the interior plateau and in many of the valleys largely gives way to open grass land. The Coast Range was formed by a great upwelling of granite and diorite as batholiths along the margin of the continent in the Jurassic. The Rocky Mountains were raised after the close of the Cretaceous by tremendous thrusts from the Pacific side, crumpling and folding the ancient sedimentary rocks, and faulting them along overturned folds. The outer ranges in Alberta have usually the form

#### SCENES FROM FOUR PROVINCES OF CANADA

1. View of Moraine lake in the province of Alberta, Canada, situated in the valley of the Ten Peaks about 9 miles from Lake Louise. The ten peaks, each of which is at least 10,000 ft. high, surround the lake on the eastern and southern sides
2. A saw mill at Coal Creek, British Columbia
3. An experimental farm near Cochrane, Alberta. A field of oats is shown with the Rocky Mountains in the distance. Huge ranches are found in the lower part of this section, while on the higher terraces herds of cattle and sheep are raised
4. A view of the city of Moose Jaw in the province of Saskatchewan. This city, which is situated on the Moose Jaw river, is in the centre of the wheat growing district and is one of the largest milling points in the province
5. View of the harbour at Montreal, Quebec, situated at the confluence of the St. Lawrence and Ottawa rivers. Some of the wharves and docks, which are built of solid masonry and extend for miles, are shown
6. King street in Toronto, looking east. Toronto, situated on the northern shore of Lake Ontario, is the capital and largest city of Ontario

of tilted blocks with a steep cliff towards the north-east and a gentler slope, corresponding to the dip of the beds, towards the south-west. Near the centre of the range there are broader foldings, carved into castle and cathedral shapes. The most easterly range was pushed 7 m. out upon the prairies.

In the Rocky Mountains proper no ore deposits are known, but in the Cretaceous synclines which they enclose, valuable coal basins exist. The coking coals of the Fernie region supply the fuel of the great metal mining districts of the Kootenays in British Columbia, and of Montana and other states to the south. In the Coast and Gold Ranges there are important mines of gold, silver, copper and lead and in early days the placer gold mines of the Columbia, Fraser and Cariboo attracted miners from everywhere, but these have declined, and lode mines supply most of the gold as well as the other metals. The Atlin and White Horse regions in northern British Columbia and southern Yukon have attracted much attention, and the Klondike placers still farther north have furnished many millions of dollars' worth of gold, but are now almost worked out.

**Climate.**—In a country like Canada ranging from latitude  $42^{\circ}$  to the Arctic regions and touching three oceans, there must be great variations of climate. If placed upon Europe it would extend from Rome to the North Cape, but latitude is of course only one of the factors influencing climate, the arrangement of the ocean currents and of the areas of high and low pressure making a very wide difference between the climates of the two sides of the Atlantic. The Pacific coast of Canada, rather than the Atlantic coast, should be compared with western Europe, the south-west corner of British Columbia, in latitude  $48^{\circ}$  to  $50^{\circ}$ , having a climate very similar to the southern coast of England.

In Canada the isotherms by no means follow parallels of latitude, especially in summer when in the western half of the country they run nearly north-west and south-east, so that the average temperature of  $55^{\circ}$  is found about on the Arctic circle in the Mackenzie river valley, in latitude  $50^{\circ}$  near the Lake-of-the-Woods, in latitude  $55^{\circ}$  at the northern end of James Bay, and in latitude  $49^{\circ}$  on Anticosti in the Gulf of St. Lawrence. It is impossible to describe even the climate of a single province, like Ontario or British Columbia, as a unit, as it varies so greatly in different parts. Details should therefore be sought in articles on the separate provinces. South of the Gulf of St. Lawrence the maritime provinces average  $40^{\circ}$  for the year and over  $60^{\circ}$  for the summer months. The amount of rain is naturally high so near the sea, 40 to 56 in., but the snowfall is not usually excessive. In Quebec and northern Ontario the rainfall is diminished, ranging from 20 to 40 in., while the snows of winter are deep and generally cover the ground from the beginning of December to the end of March. The winters are brilliant but cold, and the summers average from  $60^{\circ}$  to  $65^{\circ}$ , with clear skies and a bracing atmosphere which makes these regions favourite summer resorts for the people of the cities to the south. The winter storms often sweep a little to the north of southern Ontario, so that what falls as snow in the north is rain in the south, giving a much more variable winter, often with little snow. The summers are warm, with an average temperature of  $65^{\circ}$  and an occasional rise to  $90^{\circ}$ .

As one goes westward the precipitation diminishes, most of it, however, coming opportunely from May to August, the months when the growing grain most requires moisture. There is a much lighter snowfall than in northern Ontario and Quebec, with somewhat lower winter temperatures. The precipitation in southern Saskatchewan and Alberta is much more variable than farther east and north, so that in some seasons crops have been a failure through drought, but large areas are now being brought under irrigation to avoid such losses. The prairie provinces have a distinctly continental climate with comparatively short, warm summers and long, cold winters, but with much sunshine in both seasons. In southern Alberta the winter cold is often interrupted by chinooks, westerly winds which have lost their moisture by crossing the mountains and become warmed by plunging down to the plains, where they blow strongly, licking up the snow and raising the temperature, sometimes in a few hours from  $20^{\circ}$  to  $40^{\circ}$ . In this region cattle and horses can generally winter on the grass of the ranges

without being fed. With sunshine for twenty hours out of twenty-four in June, growth is almost the same in the north as for hundreds of miles to the south, so that wheat and vegetables ripen in the Peace river valley in latitude  $56^{\circ}$ .

The climate of the Cordilleran region presents even more variety than that of the other provinces because of the ranges of mountains which run parallel to the Pacific. Along the coast itself the climate is insular, with little frost in winter and mild heat in summer, and with a very heavy rainfall amounting to 100 in. on the south-west side of Vancouver Island and near Prince Rupert. Beyond the Coast Range the precipitation and general climate are comparatively mild and with moderate snowfall towards the south, but with keen winters farther north. The interior plateau may be described as arid, so that irrigation is required if crops are to be raised.

The Selkirk Mountains have a heavy rainfall and a tremendous snowfall on their western flanks, but very much less precipitation on their eastern side. The Rocky Mountains have the same relationships but the whole precipitation is much less than in the Selkirks. The temperature depends largely, of course, on altitude, so that one may quickly pass from perpetual snow above 8,000 ft. in the mountains to the mild, moist climate of Vancouver or Victoria. North-west and north-east of Hudson Bay the climate becomes too severe for the growth of trees, and there may be perpetual ice beneath the coating of moss which serves as a non-conducting covering for the "tundras." Leaving out the maritime provinces, southern Ontario, southern Alberta and the Pacific coast region on the one hand, and the Arctic north on the other, Canada has snowy and severe winters, a very short spring with a sudden rise of temperature, short, warm summers and a delightful autumn with its "Indian summer." There is much sunshine, and the atmosphere is bracing and exhilarating. (A. P. Co.)

**Flora.**—The general flora of the Maritime Provinces, Quebec and Eastern Ontario is much the same, except that in Nova Scotia a number of species are found common also to Newfoundland that are not apparent inland. In New Brunswick the western flora begins to appear as well as immigrants from the south, while in the next eastern province, Quebec, the flora varies considerably. In the lower St. Lawrence country and about the Gulf many Arctic and sub-Arctic species are found. From the city of Quebec westwards there is a constantly increasing ratio of southern forms, and when Montreal is reached the representative Ontario flora begins. In Ontario the flora of the northern part is much the same as that of the Gulf of St. Lawrence, but from Montreal along the Ottawa and St. Lawrence valleys the flora takes a more southern aspect, and trees, shrubs and herbaceous plants not found in the eastern parts of the Dominion become common.

In the forest regions north of the lakes the vegetation on the shores of Lake Erie requires a high winter temperature, while the east and north shores of Lake Superior have a boreal vegetation that shows the summer temperature of this enormous water-stretch to be quite low. Beyond the forest country of Ontario come the prairies of Manitoba and the North-West Territories. In the ravines the eastern flora continues for some distance, and then disappearing gives place to that of the prairie, which is found everywhere between the Red river and the Rocky Mountains except in wooded and damp localities. Northwards, the flora of the forest and that of the prairies intermingle. On the prairies and the foot-hills of the Rocky Mountains a great variety of grasses is found. Besides the grasses there are many leguminous plants valuable for pasture.

About the saline lakes and marshes of the prairie country are found *Ruppia maritima*, *Heliotropium curassavicum*, natives of the Atlantic coast, and numerous species of *Chenopodium*, *Atriplex* and allied genera. The flora of the forest belt of the North-West Territories differs little from that of northern Ontario. At the beginning of the elevation of the Rocky Mountains there is a luxurious growth of herbaceous plants, including a number of rare umbellifers. At the higher levels the vegetation becomes more Arctic. Northwards the valleys of the Peace and other rivers differ little from those of Quebec and the northern prairies. On the western slope of the mountains, that is, the Selkirk and Coast
